The height of the support is so adjusted that a distance of 100 mm. intervenes between the bottom of the pin *s* and the top of the support, and then, the rod being allowed to fall, the time required for it to sink this distance is observed. There are three rods of the dimensions given above, which are composed respectively of brass, zinc, and glass, and weigh respectively 150, 100, and 50 grms. The glass rod is used for determining the consistency of the softest greases; the brass rod that of the most solid.

The author gives the following examples of the results obtainable by this method:—

Lubricating Grease.	Price per 100 Kilos.	Time (in Seconds) required in Sinking 100 Mm.		
		Brass Rod.	Zinc Rod.	Glass Rod.

The Varnish and Wax Productions of China. Consul Gardner. Foreign Office Annual Series, No. 888.

THE varnish exported from the district round about Hankow is the gum of a tree—the *Rhus vernicifera*. On this tree,

before daylight, incisions are made; the gum that runs out is collected in the dark and strained through a cotton-cloth bag, leaving behind a large amount of dirt and refuse. This operation can only be performed in the dark, as light spoils the gum and causes it to cake with all the dirt in it. It cannot be strained in wet weather, as moisture causes it to solidify. When the Chinese use this varnish they rub it on with a sort of mop, or swab, made of soft waste silk. It should only be used in wet weather, as if the atmosphere be dry when it is rubbed on it will always be sticky. As used by the Chinese this varnish takes about a month to dry. During the time it is drying it is poisonous to the eyes. Consul Gardner thinks it possible that the celebrated Cremona varnish may have had in it some of this gum as one of its ingredients, and he suggests that it might be worth the while of our musical instrument makers to make experiments with this gum with a view to producing a varnish that would give a mellow instead of a glassy sound. White wax is produced by a winged insect of the family of *Jalgoradi*, order *homoptera*. In the production of this commodity the insect at a certain stage of its development is moved from one kind of tree to another. It is believed that the trees on which the insect is reared are the *Ligustrum lucidum* and the *Ligustrum japonicum*. The wax is particularly hard, and is used in China for casing tallow candles. Two facts account for the decreased export in 1890, as compared with 1889, of 835,793 lbs., or nearly 40 per cent. First, the increased use by Chinese of kerosine oil, causing a decreased demand for tallow candles; and, secondly, in England, the extended use of paraffin candles and of electricity reduced the selling price of white wax in Shanghai to below its cost of production. It would seem, therefore, that unless a cheaper mode of production can be discovered, or other uses of the commodities be found, the interesting industry of producing white wax is a doomed one.

Vegetable-Oil Production in China. Report by Consul Warren on the Trade of Taiwan (Formosa).

CONSUL WARREN states that from the ground or pea nut, which is largely cultivated throughout the plain lying between the hills and the west coast of South Formosa, is expressed an oil which is in great request all over the island, both as an article of food and for lighting purposes. The supply of this is insufficient to meet the demand, and large quantities of nuts are imported by junk from the Pescadores, which are said to be of a finer quality than those produced in Formosa. The nuts are first dried in a brickwork tank, under which a slow fire is kept constantly burning; they are then crushed by means of a horizontal roller, forming the radius of the circle which it works in, the machine being driven by oxen. By this means the husks are broken up and the kernels cracked. It takes about six hours to crush 14 cwt. of nuts in an ordinary sized mill. The mass is then sifted to clear it of the larger portions of husk, which latter are again put under the crusher. The pulverised mass is made into circular cakes, which are wrapped round with rice-straw, twisted together at the rims. These cakes are then put into a press, which is formed by two semi-cylinders, resembling in form native cotton-balls, which, when placed together, form a complete closed cylinder, the two parts of the press being kept together by iron bands. Each of the cakes is surrounded with an iron ring, and they are arranged in loose, but regular, order throughout the length of the press. A wedge is then inserted between the last cake and the end of the press, and is driven home by means of a swinging-hammer. Another wedge is inserted and treated in a similar manner, and this is continued until the whole mass is so closely pressed together as to render further insertion of wedges impossible. As the oil drains out and the pressure slackens, more wedges are driven in until the whole of the oil has been expressed; 1 cwt. of nuts will give about 25 lb. of oil, worth 30s. The leaves and stalks of the plant are sometimes worked into the soil, and form very good manure; they are also largely used as food for cattle, and are extremely nutritious. The method of extracting pea-nut oil as above detailed seems somewhat cumbersome, taking a considerable time and involving great waste of material; but, seeing that labour is so cheap and that the

people have for so long a time been accustomed to the machine now in use, it appears doubtful whether the introduction of more elaborate machinery would be of any practical use. Such an introduction has been often proposed, but hitherto no effective steps have been taken to carry it out. Castor oil is another of the products of the south of Formosa to which little or no attention has been paid. The castor-oil plant (*Ricinus communis*) grows wild over the greater portion of the known districts of South Formosa. No attempt is made by the natives to cultivate it, and, with the exception of a small quantity of crude oil, which is expressed for use in mixing with ink for stamps and printing, as far as is known no effort has ever been made to obtain the oil in sufficiently large quantities to make it worth while exporting it. This is strange, seeing that the natives are well aware of the medicinal properties of the oil, and purchase and use freely that which is imported from foreign countries. As a lubricant castor oil is daily becoming in greater demand throughout the world, and there is no doubt that, considering the ease with which the raw material can be obtained, and the comparatively simple method necessary for extracting the oil, there is a large and profitable opening for capital and enterprise in this direction. Large tracts of land that are now considered useless for ordinary cultivation would suit admirably for the growth of the castor-oil plant, which, indeed, is often the only form of vegetation to be met with on them.

PATENT.

Improved Method of Decolourising Mineral, Animal, and Vegetable Oils, Fats, and the like, and the Employment of Silicic Acid for the Purpose. H. Stern, Warsaw, Russia. Eng. Pat. 7142, May 7, 1890. 6d.

When silica obtained by precipitation from soluble silicates is well washed and perfectly dried, it constitutes a cheap decolourising agent which has no chemical action on any oil but only retains the colouring material. The silica is added to the warm or cold oil and the mixture filtered, or the oil is passed through a filter-bed filled with silica. To regenerate the filtering material it is washed with a suitable solvent for the substance under treatment and if necessary ignited.—K. E. M.

Improvements in the Manufacture of Waterproof Boards, Paper, and such like Materials. C. Weygang, London. Eng. Pat. 3004, February 25, 1890. 8d.

Porous substances, such as moss peat, wood pulp or porous paper, boards, or more or less felted tarrys are saturated with preparations of resinous, oily, tarry, fatty, or similar substances, e.g., by saponifying common resin with tallow, then adding petroleum, or tar, &c., and afterwards diluting with water. Moss peat, wood pulp, &c., after being treated in this way, are ground in edge-runners and then added to ordinary paper stock in the beating engine. Free alkalis, if

present, have to be neutralised. Peat boiled with caustic alkali or a farinaceous substance (compare Eng. Pat. 7904, 1886) may be added to the materials while in the beater as a hardening or binding agent. Antiseptic, disinfecting or similar substances can be added as well if desirable. The pulp is manufactured into boards or paper in the ordinary way.—H. S.

An Improved Method of and Apparatus for Preparing Copal and other Gum Resins and Resins, and Manufacturing Varnish. A. F. St. George, Redhill. Eng. Pat. 5380, April 9, 1890. 8d.

This inventor employs a melting pot provided with cooling tubes or condensers, and communicating with a still or retort, and treats the gum resins or resins "by digestion in their own vapours or distillates," for the purpose of rendering them more readily soluble in oils or spirits.—E. G. C.

Improvements in or Appertaining to Paints, Colours, Varnishes, and Distempers, and in the Method of Applying them to Canvas or other like Surfaces. W. P. Thompson, Liverpool. From A. F. von Pereira, Stuttgart, Germany. Eng. Pat. 6805, May 2, 1890. 6d.

The medium with which the inventor mixes majolica colours, consists of glycerin, 40 grms., oleum rosarum palmarum, 10 drops, and liquid yellow honey, 60 grms. The varnish necessary for these paints is composed of rectified alcohol, $\frac{1}{2}$ litre, balsam of copaiva, 2 grms., mastie, 8 grms., rectified turpentine oil, 8 grms., and Venice turpentine, 6 grms. The canvas is coated with a mixture of white or red pipe clay, glue and honey.—E. G. C.

Improvement in the Manufacture of Varnishes. B. Piffard, Hemel Hempstead. Eng. Pat. S668, June 4, 1890. 4d.

This improved varnish consists of the lead salts of the isomeric acids constituting colophony and is prepared as follows:—2 parts of rosin are mixed with 1 part of lead oxide and $\frac{1}{12}$ to $\frac{1}{8}$ part beeswax or paraffin is added. The mixture is then heated in an oven at about 250 F. until combination is obtained and the excess of lead oxide has subsided. The product called "Artificial Copal," is allowed to cool and ground to a fine powder. The powder is then dissolved in turpentine or other suitable solvent in the proportion of 2 parts by weight of the lead salt to 3 parts fluid measure of the solvent. The varnish may be used either hot or cold and hardens rapidly.—B. H.

An Improved Ink. T. W. Just, R. Weiler, and O. Heidepriem, Melbourne, Australia. Eng. Pat. 16,757, October 21, 1890. 4d.

See under VI., page 541.

Improved Anti-Corrosive and Anti-Fouling Compounds. M. E. Dejonge, Stapleton, U.S.A. Eng. Pat. 19,160, November 25, 1890. 4d.

The materials used are colophony, paraffin, fusel oil, zinc dust, and tale or asbestos.—E. G. C.

Improvements in and relating to the Manufacture of Insulating Compositions for Electrical Uses. T. D. Bottome, Hoosick, U.S.A. Eng. Pat. 20,289, December 12, 1890. 4d.

Process for Converting Carbonate of Lead, obtained by Decomposition of Sulphate of Lead or other Compound of Lead with Carbonate of Sodium, into Basic Salt. J. N. Zeidler, Cannstatt, Germany. Eng. Pat. 2812, February 16, 1891. 4d.

This invention relates to a process for producing white lead from various salts of lead, principally the sulphate, obtained as by-products in different manufactures. The amount of lead is first determined in the product to be treated, and it is then converted into neutral carbonate of lead by treatment with the proper quantity of carbonate of sodium. The neutral carbonate of lead so obtained is then converted into basic carbonate ("white lead") by boiling it with the requisite amount of caustic soda lye, the following reaction taking place:—

The white lead is then separated from the solution, washed and dried.—B. H.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

The Theory of the Currying Process. W. Fahrion. Zeits. f. angew. Chem. 1891, 172—175.

CURRYING consists in dressing the properly prepared hides with train oil, and subsequently exposing them to the atmosphere. This will give rise to chemical reactions accompanied by an elevation of temperature, under the influence of which substances are formed, which possess the property of converting hide into leather.

The nature of this process may be elucidated by investigating the *dégras* (moëllon) or surplus oil remaining after pressing the hides.

Jean found (Monit. Scient. 15, 1889), that this *dégras* contains about 10—20 per cent. water, and that its property of forming emulsions with water depends on the presence of a "resinous substance." This he considered to be a product of the oxidation of train oil, and found it to be insoluble in petroleum ether. As any *dégras* is perfectly soluble in petroleum ether, it follows that this "resinous substance" must have been formed in the currying process.

According to Schreiner (Ledermarkt. 38, 51, 1888), the main product of the oxidation is a glyceride of dioxy palmitic acid.

Eitner (Der Gerber. 375, 1890), however, disputes the oxidising nature of the process, and finds that train oil in contact with animal fibre produces a nitrogenous substance, which on its part will give rise to a sort of after-tanning in the oiled leather. This "tanning substance" is to be found in train oils ready formed and in varying quantities.

Sinand describes this substance as the *dégras* former.

The author's investigations lead him to believe that Jean's old oxidation theory offers the correct explanation of the currying process. He oxidised cod-liver oil with nitric acid, extracted the saponified product with petroleum ether, and the residue with ether. The ether solution yielded, on nitrifying, yellow crystals, which melt at 35°, and which may also be isolated from tallow, olive oil, linsed oil, and palm oil, a proof that the ether solution consisted of an hydroxyoleic acid. The insoluble part yielded on nitrifying an amorphous yellow substance, which is characteristic of train oil. Its analysis shows that train oil contains in all likelihood an unsaturated fatty acid of the formula $\text{C}_{16}\text{H}_{32}\text{O}_2$, but besides this it may contain one or more unsaturated fatty acids.

The author succeeded in separating from the *dégras* and from the curried hide the above yellow crystals and the amorphous yellow substance, thus proving that the process is an oxidising one.

As to Eitner's "nitrogenous substance" or "tanning substance" the author finds that the nitrogen is due to impurities. On exposing curried and oiled hide to the atmosphere for about three months, and extracting part of

it with ether, a yellow fat will result, which, on saponifying and treatment with petroleum ether, will yield about 22 per cent. of the *dégras* former. This was found to contain nitrogen. However, on shaking the ether solution with water, filtering, and evaporating, the *dégras* former proved to be free from nitrogen. It is now evident that the *dégras*, in contact with the hide, takes up nitrogenous substances, which it retains with great tenacity. It will be also seen that old tann oil contains more of the *dégras* former than fresh oil, which again only strengthens the supposition that the *dégras* former is a product of oxidation. The substances known as "poisonous substance," "tanning substance," and *dégras* former, the author proposes to name "oxyfatty acids" or "oxyacids."—H. A.

Elephant Leather. Journal of Commerce, Boston.

The tanning of elephant hides is comparatively a new industry. The method employed is practically the same as in the tanning of cow hide, except that a stronger combination of the tanning ingredients is required, and greater length of time, about six months, is necessary to perform the work. When the hide is taken out of the vat it is $1\frac{1}{2}$ in. thick. Articles made of elephant hides are expensive luxuries. A small pocket-book of elephant's leather, without any silver or gold ornamentation, costs about 8*l*. A small satchel made of the same leather costs from 6*l*. to 8*l*. Cigar cases, card cases, and similar articles vary from 5*l*. to 20*l*. Floor rugs are also made out of the leather. In finishing the hide no attempt is made to glaze or polish it. Everything is done to preserve its natural colour and appearance. It is a very enduring leather, several years' wear having but little effect on it.

PATENTS.

Improvements in or relating to the Waterproofing of Leather or Pulp Boards and the like. C. L. Lawrence, Leicester. Eng. Pat. 19,216, November 26, 1890. 6*d*.

The leather or pulp boards, either in the sheet or cut out into blanks or soles, are waterproofed by putting them through a solution of paraffin wax in "benzoline," and then immediately passing them over hot plates or through hot air or over steam cylinders.—B. H.

A New or Improved Process for Utilising Leather Waste and Preparing therefrom a Material for Covering Floors, Walls, Roofs, and the like. W. Barton, Rixdorf, Germany. Eng. Pat. 2808, February 16, 1891. 4*d*.

The waste leather is first dried, by placing it in a steam-jacketed boiler and heating it, with constant stirring, for three hours. It is then passed between hot rollers. To reduce the waste to a still finer powder, it is again heated and dried, and then ground under stones, preferably granite.

The leather powder is then mixed with hand-boiled linseed oil, then with burnt and sieved lime, next with colouring matter, and finally with a mixture of colophony and petroleum. The resulting mixture is subsequently pressed between iron rollers upon jute, linen, or other suitable material.—B. H.

XV.—MANURES, Etc.

Removal of Vapours containing Fluorine in Manure Works. Chem. Ind. 13, 493.

A GOVERNMENT commission in Copenhagen has been investigating this question at a manure works in that city, and has adopted the following method, said to be effective, in preventing the nuisance arising from the bad-smelling and injurious vapours, containing hydrofluoric and hydrofluosilicic acids, which are produced invariably in superphosphate works where raw material containing fluorine compounds is acted on by sulphuric acid.

The bad-smelling vapours are drawn out of the mixing machine and mixing chamber by a fan, care being taken to avoid undue admixture with air. The gases are then mixed with steam from a jet and are led into a good-sized chamber where they are brought in contact with water-spray thrown from two or three Korting sprays or Grinnel's fire extinguishers. The fluorine compounds are dissolved by the water, and, together with the finely-divided silica, are deposited in the chamber. If the chamber is large enough the working is very effective. To remove the last traces of fluorine, the vapours are finally driven through a large filter made of pieces of quartz about the size of hazel nuts, so as to form a layer or bed about 1 metre thick, which is kept constantly moistened with cold water.

The slightly acid wash-waters are run directly into the sewers, but they can be run off without doing any harm in an open drain, or if need be, they can be neutralised with lime before running off. (See also this Journal, 1891, 338—340.)—H. S. P.

XVI.—SUGAR, STARCH, GUM, Etc.

Some Derivatives of Levulose-Carboxylic Acid. G. Düll. Ber. 24, 348—351.

Action of Ammonia.—If a strong solution of levulose-carboxylic acid be saturated with ammonia, and allowed to stand a short time, prismatic crystals of the ammonium salt are deposited. Acids forming lactones when treated thus sometimes yield amides. Dextrose-carboxylic acid behaves like the levulose derivative.

Oxidation.—Levulose-carboxylic acid is oxidised with dilute nitric acid at 40 °C. The solution is evaporated to a syrup and extracted with ether until all the nitric and oxalic acids have been removed. The residue is neutralised with potash and calcium chloride added until the precipitate which first forms is re-dissolved. On standing a difficultly soluble calcium salt is deposited as a crust. The purified salt has a composition corresponding to the formula $(C_7H_7O_{10})_2Ca_3 \cdot 6H_2O$. The free acid is obtained by decomposing the calcium salt with its equivalent of sulphuric acid and extracting with alcohol. The alcoholic solution is evaporated to a syrup, and from this large colourless crystals separate, which may be dried over sulphuric acid. Their composition corresponds with the formula $C_7H_9O_{10}$. It requires three equivalents of potash to neutralise it. This body is therefore a tribasic acid having the constitution—

and may be called tetrahydroxy-n-butenyl-tricarboxylic acid. It melts at 146—147°, and appears to form a lactone.

The acid forms well-crystallising salts. The potash salt is very characteristic, forming large prismatic crystals $2(C_7H_7O_{10})_2K_2 \cdot 3H_2O$. The acid yields a phenylhydrazide occurring in tufts of fine long yellow crystals; it is insoluble in cold water, alcohol, and acetic acid, it dissolves in cold concentrated sulphuric acid with a violet colouration. It contains two phenylhydrazine groups in the molecule.

—A. L. S.

Reduction of Saccharic Acid. E. Fischer and O. Piloty. Ber. **24**, 521—528.

THE authors have already (this Journal, 1890, 638), shown that saccharic acid on reduction yields an acid closely resembling glucuronic acid. They now prove that these bodies are identical.

Synthesis of Glucuronic Acid.—Saccharic acid is reduced by sodium amalgam, the solution being cooled in ice and kept always acid with sulphuric acid. The reduced solution is neutralised, concentrated, and poured into hot alcohol. The acid contained in the alcoholic liquid is purified by first preparing its barium salt and then its lead salt; the purified concentrated solution of the acid deposits, crystals of the lactone of glucuronic acid, which is identical with the lactone prepared from other sources, melting point 175.8° $[\alpha]_D = +19.1$ in a 4 per cent. solution.

d-Gulonic Acid.—By the further reduction of glucuronic acid, or preferably by the reduction of saccharic acid, an acid is obtained which the authors have called gulonic acid. When the reduction has proceeded until the solution has lost the power of reducing Fehling's solution, all the glucuronic acid has been reduced. The reduced solution is acidified and poured into hot alcohol, the alcoholic solution is concentrated, neutralised with baryta, and evaporated to a syrup; the syrup is dissolved in a little water, and the unaltered barium saccharate crystallises out, the barium is removed from the mother-liquor by sulphuric acid, and the syrup which remains deposits crystals of the lactone of gulonic acid. The purified lactone melts at 180° , and has $[\alpha]_D = +55.1$. It forms a phenylhydrazide, melting point 147° — 149° , which is soluble in hot water and alcohol.

d-Gulose is produced by the reduction of gulonic acid by sodium amalgam. It forms a colourless syrup, easily soluble in water and difficultly soluble in absolute alcohol. It is with difficulty, if at all, fermentable by beer yeast. When oxidised both *d*-gulose and *d*-gulonic acid yield saccharic acid; *d*-gulose yields an osazone totally different from *d*-glucosazone. The following formulae show the relation of these new products to glucose, gluconic, and saccharic acids:—

—A. L. S.

On Xylose. E. Fischer and R. Stahel. Ber. **24**, 528—529.

THE authors have recently shown that a carboxylic acid may be prepared from xylose in the usual way (this Journal, 1890, 1053; also 1891, 473). This acid now proves to be the optical opposite of *d*-gulonic acid (see previous abstract), and may be therefore called *l*-gulonic acid. The composition of its lactone is expressed by the formula $\text{C}_6\text{H}_{10}\text{O}_6$, melting point 185° . Its solution is levorotatory, having $[\alpha]_D = -55.3$. It forms beautifully large crystals of the lactone, which have been measured. It is easily soluble in hot water, but only with difficulty in cold water and alcohol. It has a sweet taste and neutral reaction; on standing its solutions become acid, owing to the hydration of the lactone. It forms a phenylhydrazide, melting point 147° — 149° , and which is much more soluble in water than the corresponding compounds of gluconic and mannonic acid.

l-gulose is obtained by reducing the above lactone by sodium amalgam, the solution being kept acid by sulphuric acid. The reduced solution is neutralised and concentrated and poured into hot absolute alcohol; the alcoholic solution is distilled and the sugar obtained as a colourless syrup. It has a sweet taste, is unfermentable, and slightly dextrorotatory. It yields a hydrazone forming white needles, melting point 143° , easily soluble in warm water, but only moderately so in cold water and absolute alcohol. The sugar also yields an osazone, forming a yellow crystalline mass, melting point 156° . It is appreciably soluble in hot water, and thus differs from the osazones of all the natural hexoses, and resembles those of arabinose and xylose, and very closely *β*-acrosazone; and it is possible that this may be the inactive form of it.

l-gulonic acid lactone is obtained by mixing solutions of equal quantities of *d*- and *l*-gulonic acids. On concentration the inactive lactone separates out in well formed crystals.

Oxidation of l-gulonic acid.—When oxidised by nitric acid *l*-gulonic acid yields *l*-saccharic acid.

Reduction of l-gulose.—It is preferable to start with the lactone of *l*-gulonic acid and reduce this as far as possible by sodium amalgam; during the latter part of the reduction the solution is allowed to become just alkaline. When the reduction is complete the solution no longer reduces Fehling's solution. As dextrose and ordinary saccharic acid when reduced yield sorbitol, *l*-gulose would probably yield *l*-sorbitol. The product of the reduction closely resembles sorbitol and is purified by means of the benzaldehyde compound; this compound also resembles the corresponding one of sorbitol. The alcohol obtained appears to be *l*-sorbitol, as it differs in no way from natural sorbitol except that a solution of it containing borax is levo-rotatory whilst a similar solution of the natural product is dextro-rotatory.

Constitution of gulonic acid.—As *d* gluconic and *d* gulonic acids yields the same saccharic acid, and the same holds good for the two *l*-acids, the constitution of gulonic and gluconic acids can only differ as the two following formulae:—

Constitution of xylose.—The ease with which xylose yields furfural renders it probable that this sugar contains a normal carbon chain. The above results render this certain, and show that it belongs, like arabinose, to the *l*-mannitol or *l*-sorbitol group. It appeared possible that xylose might be related to arabinose like gluconic and gulonic acids are to one another; in this case both sugars should yield the same alcohol on reduction; this, however, is not the case. Xylose is reduced by sodium amalgam, and the reduced alcohol purified by means of the benzaldehyde compound, the purified alcohol, xylitol, is quite different from arabitol. It could not be obtained crystallised.—A. L. S.

On d- and l-Manno-saccharic Acid. E. Fischer. Ber. **24**, 539—546.

KILIANI (Ber. **20**, 341) obtained by the oxidation of arabinose-carboxylic acid, an acid forming a well crystallising double lactone, and which he called meta-saccharic acid. As arabinose-carboxylic acid has been shown to be *l*-mannonic acid, it is preferable to call meta-saccharic acid, *l*-manno-saccharic acid. Fischer has prepared the corresponding *d*- and *l*- varieties of this acid as follows:—

d-Manno-saccharic acid is prepared by oxidising *d*-mannonic acid by nitric acid. The calcium salt of the new acid is prepared, this crystallises out and from this the calcium is removed by oxalic acid, and the double lactone of *d*-manno-saccharic acid crystallises from the solution. It forms colourless long needles, having the formula $\text{C}_6\text{H}_8\text{O}_6$, melting point 180° — 190° .

It reduces Fehling's solution, is easily soluble in hot water, but not very in cold, in which it differs from the *l*-acid of Kiliani which is fairly soluble in cold water. It is dextro-rotatory, having $[\alpha]_D = +201.8$; the author has examined

the *D*-acid and finds it just as strongly rotatory, but in the opposite direction. The two acids combine to form an optically inactive acid. The *D*-acid is most conveniently prepared from mannose. Shaken with ammonia, the double lactone of *D*-mannosaccharic acid yields a diamide, of which the formula is $C_6H_8N_2O_4$. It forms colourless crystals, melting point 189°. With phenylhydrazine this acid forms a monophenylhydrazide, forming colourless microscopic needles, easily soluble in hot water, but with difficulty in cold, melting point 190°—191°; and a diphenylhydrazide crystallising in glistening plates, melting point 212°.

Mannosaccharic acid may be prepared by mixing the two active acids or by the oxidation of *D*-mannonic acid. It crystallises in fine long prisms, melting point 190°, easily soluble in warm water but with difficulty in alcohol. Its compounds closely resemble those of the *D*-acid described above. The diamide forms tabular crystals, melting point 183°—185°. The monohydrazide is fairly easily soluble in hot water, melting point 190°—195°; the dihydrazide forms fine colourless plates, melting point 220°—225°.

Of the 10 theoretically possible acids of the hexoses containing a normal carbon chain, there are already six known, namely, two active saccharic acids, two active mannosaccharic acids, mucic acid, and Tieman's tri-saccharic acid. The author has obtained a seventh by heating galactonic acid with quinoline to 145°, when it becomes changed into an isomeric body and oxidising this. The acid will be described in a future communication.—A. L. S.

The Quantitative Estimation of Penta-glucosins in Plants. G. de Chalmot and B. Tollens. Ber. 24, 694—695.

On the Adulteration of Gum Arabic. A. Jacksch. Chem. Zeit. 15, 77.

THE disturbances in the Soudan and other countries of Inner Africa are well known to be the only cause that good gum is at present rare and expensive (compare this Journal, 1890, 905). The consequence is that other substances are introduced from Australia, South America, and other countries as a substitute. None of them, however, are as good as the genuine gum arabic. Besides these, other substances have been sold which are insoluble by ordinary means, and the quality of which is very bad. Lately such inferior materials have been brought into the market mixed with gum Ghezi and sold as "gum in granulis," and many times have been deceived in consequence. It is impossible to recognise this by simply dissolving the substance, as the gelatinous parts are suspended in the solution and remain invisible, but the adulteration can easily be detected by the following test.—Some of the substance is mixed with 10 times its quantity of hot water, and allowed to stand for three or four hours. During this time it must be stirred at intervals. After the insoluble parts have settled down one half of the liquid is poured off, the same quantity of cold water added, the whole again stirred, and then allowed to stand. In the course of the next hour this must be repeated twice. The last of these mixtures after a short time separates into two parts, the upper one of which consists of water, and the lower of a gelatin-like substance. As little as 5 per cent. of the adulteration can be detected in this way with accuracy.

—H. S.

Pine Tree Honey Dew and Pine Tree Honey. H. W. Wiley. Amer. Chem. J. 1891, 24—29.

HONEY at one time was supposed to be practically nothing else but invert sugar, with a doubtful trace of cane sugar. In order to detect the adulteration with starch syrup, it was considered sufficient to examine a sample with the polariscope, to take its copper-reducing power, and to calculate from these data the percentage of both dextrose and levulose. If the first predominated, this was considered

sufficient evidence of adulteration with starch syrup, supposing pure invert sugar to contain equal quantities of both.

When analysts began to pay more attention to the matter, it soon appeared this was all *theory*; in fact many a 10 per cent. solution of undoubtedly genuine honey was found not to show any polarisation at all, proving a natural slight excess of dextrose. At one time analysts also thought that, if more than 2 per cent. of cane sugar was found in a sample of honey, this might be taken as an absolute proof of adulteration with cane sugar; but although this is true in a sense, it has now been ascertained beyond reasonable doubt, by the investigation of Benemann, that the bees themselves may be the real culprits, because when in the neighbourhood of sugar refineries, they swarm there in their thousands to regale themselves on the sugar. The honey they produce often contains as much as 16 per cent. of cane sugar, which Benemann thinks is caused by their lack of sufficient acidity (formic acid?) to properly invert the sugar. The analysis of honey grows in fact more and more complicated every year. Another constituent has now made its appearance. Anthor and Stern have proved that undoubtedly genuine honey may contain a fair percentage of dextrin, if the bees get a chance to feed on malt in breweries. The presence of this body cannot be proved by the simple alcohol test, as it has been proved by the investigation of Van der Marek that this test altogether fails, unless the amount of dextrin in vegetable products is considerably over 10 per cent. Anthor and Stern allowed the honey to ferment, and tested for dextrin in the resulting fluid, by a very complicated but reliable process, which was originally published in the Zeits. f. angew. Chem. 1889, 575. The present author examined the original honey-dew of the pine tree, and found it to contain 45.59 per cent. of solid matter, including 17.44 per cent. of glucose. Examined in a Ventzke's polariscope, it showed an angular deviation of 36.56° sugar-scale. Supposing the glucose to have consisted of pure invert sugar, its levogyrate influence would be equal to 4.97° of the cane sugar scale. Adding this number to the direct polarisation, will give the figure 41.53. Deducting from this the right-handed polarisation due to sucrose, viz., 8.16, we get 33.7 right-handed rotation, due to foreign bodies in the dew. Deducting this from the total solids present, viz., 45.59, this leaves us 19.99 per cent. of solid matter, of right-handed polarisation.

The author fully expected to confirm the researches of other investigators, who had found the honey produced by the bees from such dew to be also strongly right-handed, but the sample which he investigated actually showed a left-handed rotation of not less than 13° sugar scale; showing the bees had thoroughly inverted the substance.

The author will not of course draw too many conclusions from the analysis of a single sample. He hopes to further investigate the matter. Up to the present time he has, however, not come across a genuine sample of American honey which showed a right-handed polarisation, and he therefore still looks upon such samples with the greatest suspicion.—L. de K.

PATENTS.

Improvements in Washing and Cleaning Raw Sugar. G. F. Redfern, London. From M. Weinrich, St. Louis, Missouri, U.S.A. Eng. Pat. 5282, April 5, 1890. 6d.

THE raw sugar to be purified is mixed with clear syrup, and with 8—30 per cent. of some light material, such as cork, corn cobs, wood, bagasse, wood or bone char, &c., in pieces of about $\frac{1}{4}$ to $\frac{1}{2}$ of an inch in diameter, and as regular as possible. The mixture is run into a series of cylindrical vessels, resembling and connected like the cells of a diffusion battery, and is washed by means of a current of pure syrup drawn from a tank placed 40—80 ft. above the level of the apparatus. In order to prevent the separation of the sugar from the cork or other material during washing, the mass in each cylinder is covered by a perforated iron disc, moving up and down on guides. The process is worked continuously,

the clear liquor tank being always connected to that cell of the battery in which the washing of the sugar is most advanced. The washed sugar is finally separated from the admixture of inert material by sifting, or solution in water.

—H. T. P.

Improvements in the Manufacture of Sugar. G. F. Redfern, London. From M. Weinrich, St. Louis, U.S.A. Eng. Pat. 5283, April 5, 1890. 6d.

The invention relates to the filtration of sugar solutions, and to facilitate the operation the saccharine liquor is treated with any one of the following materials or with mixtures of them:—(1.) With bagasse, comminuted to a fine meal or flour. (2.) With the crude cobs of maize, comminuted to a fine meal or flour. (3.) With the charred cobs of maize, comminuted into small pieces like bone charcoal or ground to meal or flour. (4.) With ground oak bark or with any other bark containing tannin or with ground cork. (5.) With sugar cane, sorghum cane, or sugar beet comminuted to slips or slices and then dried. After treatment the solutions may be filtered by any of the usual processes.—A. J. K.

Production of a New Glutinous Material similar to Gum Arabic and other By-Products from the Seed Kernels of the Fruit of the Carob Tree (Ceratonia). A. Niemöller, Gutersloh, Germany. Eng. Pat. 7737, May 17, 1890. 8d.

The fruit of the carob tree, known as "St. John's bread," has long been cultivated as human and cattle food. The kernel consists of a red-brown and slightly lustrous shell, which encloses two hard yellowish slightly transparent discs, between which lies the germ, together with a mealy disc or layer. The two yellow transparent discs contain the glutinous body, which is very nearly equal to gum arabic in quality. The discs are ground to powder, and the glutinous substances extracted by digesting with hot water and evaporating to any desired concentration. The shell produces a colouring matter, and the mealy portion is ground up into a food-stuff.—A. J. K.

An Improved Process for Treating Vegetable Cellular Membranes with the object of obtaining Glutinous Substances. E. Steiger, E. Schulze, and C. Auer. Zürich, Switzerland. Eng. Pat. 8029, May 22, 1890. 6d.

CARBOHYDRATES occur in the most diverse cellular membranes of vegetable origin and can be converted into glutinous substances bearing a great resemblance to gum arabic. The substances principally used are the waste of field-crops of any kind, lixiviated beetroot slices, residuary liquors from the distillation of spirits, &c. The bodies are boiled with a suitable acid of one-twentieth to one-tenth per cent., or with milk of lime, with or without pressure, or with any other alkaline earth or an alkali. The liquor is now expressed, decolorised, filtered through bone-black, and evaporated to the desired consistency. If the glutinous substances be required in a very pure state, the protein substances which occur with the cellular membrane must be previously removed in the cold state by treatment with culinary salt or alkalis.—A. J. K.

XVII.—BREWING, WINES, SPIRITS, Etc.

Addition of Sugar and Water to Acid Wine. C. Amthor, Chem. Zeit. 15, 222—223.

A REASONABLE addition of sugar and water to new acid wines cannot be considered an adulteration, as it produces no injurious effects whatever, and may be a great improvement to the quality of the wines. But as an unlimited permission of adding sugar and water to wine would exert by no means a good influence upon the trade, a congress

recently held at Wiesbaden (Germany) adopted the resolution that the addition of sugar and water shall be allowed only before the new wine is drawn off for the first time. As regards the maximum quantity of sugar and water to be added, nothing has as yet been settled. Fresenius, on the above-mentioned congress, was of opinion that the proportion of 60 parts of water to 100 parts of wine should be the utmost, and the author (who founds his view on practical experience) is for a further restriction, viz., that the proportion of one part of water to two parts of wine should be the maximum, and that certain limits for the quantities of extracts, acids, and perhaps also of mineral substances in wines should be legally fixed, in order to prevent all unfair dilutions and manipulations which would prove a great drawback to the beneficial effect of adding a reasonable amount of sugar and water to new acid wine.

—H. S.

PATENTS.

Improved Appliance for Aërating Brewers' Yeast and Mixing the same with Wort and other Ingredients. F. M. Maynard, Southampton West. Eng. Pat. 6075, April 22, 1890. 8d.

THE apparatus consists of a conical or cylindrical upright vessel, inside of which is placed a second cylinder, open at both ends. The outer vessel is fitted with a steam and water-jacket. The top of the inner cylinder carries a perforated tray, whilst an agitator, shaped like a screw-propeller, is placed near its lower end. The central spindle of the agitator passes through the tray and may be turned by hand or otherwise. When the vessel is filled with wort and yeast, the agitator being rotated forces the liquid up between the outer and inner cylinders, causing it to overflow into the tray placed over the inner cylinder. The wort, passing through the holes in the tray, descends in a shower of drops, and thus becomes perfectly aerated. A tap near the bottom of the outer vessel serves for the withdrawal of the liquid after aeration.—H. T. P.

Improvements in or relating to the Preparation of Yeast and Malt, and the Fermentation of Amylaceous Matter. A. J. Boulton, London. From the "Société Générale de Maltose," Brussels, Belgium. Eng. Pat. 7098, May 7, 1890. 6d.

THE improvement in question consists in the employment of hydrofluoric acid or its salts. In order to manufacture yeast, malted grain is mashed in the usual way for three-quarters to one hour. The wort is cooled to 18°–22° C., and from 6 to 10 grms. of hydrofluoric acid, or an equivalent weight of a suitable fluoride, are added to every 100 litres of it. Yeast is then added and fermentation carried on in the ordinary way. The advantages claimed are: (1.) The usual preliminary acidification of the wort may be dispensed with and the whole process finished in 8–12 hours. (2.) The yeast forms in a uniform and reliable manner and contains much unexhausted diastase which, owing to its saccharifying action on dextrin and starch, renders this yeast peculiarly suitable for distilleries. Hydrofluoric acid may be employed in malting as follows:—8–12 grms. of the acid, or an equivalent amount of a fluoride, are added to every 100 litres of the steep liquor, germination and other operations being performed in the ordinary way. The malt obtained contains much less acid than ordinary malt, and is free from injurious ferments. As regards beer brewing, 5 grms. of hydrofluoric acid may be added to every 100 litres of wort, preferably, just before pitching.

Improvements in Machinery or Apparatus for Drying Distillers' or Brewers' Draft or Dreg, but which is also applicable for Drying other similar Materials. J. Mitchell, Edinburgh. Eng. Pat. 7728, May 17, 1890. 8d.

THIS is a slightly simpler arrangement than that described on the next page (Eng. Pat. 5004 of 1891).—A. L. S.

A Process for Preparing Raw Grain or other Amylaceous Substances for Mashing in Brewing or Distilling Operations. H. T. Brown and G. H. Morris, Burton-on-Trent, and F. R. Moritz, London. Eng. Pat. 7880, May 20, 1890. *4d.*

THE raw grain or other starchy material, previously ground or finely pulped, is mixed with water, and with 10–15 per cent of its weight of green or air-dried malt. Instead of using the green or air-dried malt itself, an infusion of green or air-dried malt may be employed. The materials are well mixed in a vessel provided with an agitator, and jacketed for altering the temperature of its contents, which should not exceed 120° F. After some time the walls of the starch cells become dissolved leaving the starch amenable to diastatic action; and rendering the material fit for use in conjunction with malt for the production of wort by mashing in the usual way.—H. T. P.

Improvements in the Manufacture of Whisky and other Spirits. J. J. Taylor, London. Eng. Pat. 8850, June 7, 1890. *6d.*

THE distilled spirit as it comes from the still is collected in a vessel having an opening at the bottom, through which the spirit passes at such a rate that the vessel remains full of spirit. This vessel then retains the lighter part of the distillate, which is also the most impure.—A. L. S.

Reek Dissipator for Improving Malt Kilns. H. W. Joyce, Great Yarmouth. Eng. Pat. 9233, June 14, 1890. *6d.*

THIS invention relates to an attachment to a malt kiln consisting of a pear-shaped air-heating chamber which is suspended above the fire in the furnace of the kiln. The chamber is supplied with cold air by a pipe passing through the wall of the kiln. The hot air ascends from the heating chamber through a vertical pipe which passes through the heat-disperser and malt floor and projects about 2 ft. above the latter. The end of this pipe is widened out considerably, forming a funnel-shaped orifice. In the enlarged end of the pipe is suspended a conical plug, similar to it in shape, but smaller in diameter, so that a space of, say 1 in., is left all round between the two. By this means the hot air is spread all over the floor of the kiln, and quickly disperses the "reek" or steam that arises from the malt.—H. T. P.

Improvements in the Process of and Apparatus for Purifying Alcoholic Liquors. D. A. Boullanger, Canteley, France, and A. Schenbert, Dresden, Germany. Eng. Pat. 9910, June 26, 1890. *8d.*

PURIFIED hydrogen is passed through the alcoholic liquids; this converts the fusel oils into resinous and insoluble matters. Air or oxygen is then passed through to free the liquid from the bad odour, and the liquid is then filtered and distilled if required.—A. L. S.

Apparatus for Distilling and Rectifying. A. G. Burkhardt, Stuttgart, and G. Schulz, Hohenheim, Germany. Eng. Pat. 1214, January 23, 1891. *6d.*

See under L, page 329.

Improvements in and relating to the Manufacture of Alcohol and in Apparatus therefor. H. H. Lake, London. From Guignard and A. Hedonn, Paris, France. Eng. Pat. 2294, February 7, 1891. *8d.*

THE juice which is to be fermented is first sterilised by heating to 125° C.; it is then cooled to 20° C. by passing it through a pipe immersed in cold water; from this it passes through a closed filter, previously sterilised by steam,

and the filtered juice is passed in a fine spray through another sterilised vessel which is supplied with sterilised air. The aerated juice then passes to a closed fermenting vessel where it is fermented with a pure culture of a selected yeast. When the juice is fermented it is separated from the yeast by a sterilised filter. The yeast is then collected in a pure form and may be used for other fermentations.

The fermented liquor is neutralised and distilled, an alcohol is thus obtained free from acid; the alcohol is redistilled from an acid solution and the result is said to be a very pure product.—A. L. S.

A Method of Improving Wine and other Alcoholic Liquors. H. J. Haddon, London. From J. Batallé, Barcelona, Spain. Eng. Pat. 2936, February 18, 1891. *4d.*

THE process consists in exposing the wine or other liquid to sunlight, the liquid being contained in bottles or, preferably, in shallow glass vessels only partially filled with it. The precipitate, which is continuously formed under these conditions, is filtered off at intervals more or less frequent according to the result required. In absence of sunlight, electric or other light, or even heat may be employed. By the above process, a degree of ageing is produced in 3–9 months, which under ordinary conditions could only be attained in 10–100 years.—H. T. P.

Improvements in Machinery or Apparatus for Drying Distillers' or Brewers' Draff or Dreg, but which is also applicable for Drying other similar Materials. J. Mitchell, Edinburgh. Eng. Pat. 5001, March 20, 1891. *8d.*

ONE or more series of horizontal troughs are arranged in a suitable air chamber. The troughs are heated by steam-jackets, and a current of air is kept through them by means of a fan. Through each trough a shaft passes, carrying a number of blades. The wet material enters on to one end of the first of a series of troughs, and is fed along and tossed up by the revolving blades to the other end of the first trough, where, by a peculiar arrangement of the blades, it is thrown into the end of the adjacent trough of the same series, and it is then passed in a zig-zag direction through each of the troughs of the series, until it is dropped from the end of the last trough into a similar series of troughs below, where it is passed through the said series in a similar manner, and so on until it is dried.—A. L. S.

Improved Means and Appliances for Preserving Flesh Food. W. S. Simpson, London. Eng. Pat. 6102, April 22, 1890. *6d.*

THE inventor proposes to preserve meat, in a raw or partly raw condition, in tins or cans of especial construction, there being an inner and an outer tin, with a space between, serving as an insulator for the protection of the contents of the inner can from the effects of atmospheric variations.

—E. G. C.

An Improved Process of Preserving Milk and Cream. W. J. Clarke, London. Eng. Pat. 6883, May 3, 1890. *4d.*

THE milk or cream is "scalded" in a water-bath, until it acquires a temperature of about 160° F., care being taken to slowly agitate it during the operation. The scalded milk or cream is then at once transferred to vessels which

have been first heated to 160°, and these "are to be completely filled and tightly stoppered, so as to exclude the air. The milk or cream having been allowed to cool in these vessels for about 24 hours, the scalding operation is to be repeated at the same temperature and in the same way as before," and the milk or cream is then sealed up in glass or earthenware vessels.—E. G. C.

(C).—DISINFECTANTS.

Antiseptic Treatment of Building Materials. Résumé by E. Dollfus of a communication from V. Bovet. Bull. Soc. Ind. Mulhouse, 1890, 546—549.

THE author points out the necessity, on hygienic grounds, for the use, in building and decorating dwelling-houses, of thoroughly aseptic materials, and for public buildings, such as hospitals and barracks, of materials rendered, by impregnation or admixture with suitable substances, as antiseptic as possible. The antiseptic substances which may be used for this purpose are limited to such as are inoffensive to health. For this reason the employment of corrosive sublimate, sometimes recommended by medical men, is inadmissible. The new antiseptic compounds, zinc salicylate and hydroxynaphthoic acid, are recommended by the author as possessing special advantages. A one per cent. solution of the first salt not merely prevents the putrefaction of fresh meat, but effectually arrests decomposition when it has already commenced. The salt, moreover, is not dangerous to health. Injections of it administered subcutaneously to rabbits did not make the animals ill. Its action on those who dip their hands into solutions of it is confined to a partial destruction of the skin. It may be advantageously used for impregnating wall-papers, hangings, &c. For use in mixing plaster, a five per cent. solution is recommended; woodwork should be well moistened several times with a four per cent. solution. Plaster to which zinc salicylate has been added sets well, but takes a pink colouration, which, however, disappears under the influence of light.

Hydroxynaphthoic acid, on account of its feeble solubility, must be mixed in the powdered state with the plaster before adding water. It communicates to the plaster a brown colour, which is destroyed by exposure to light. The salts of this acid have no antiseptic power. It has not been determined whether the acid is completely innocuous.

According to Bovet, the additional expense of the antiseptic treatment of building materials does not amount to more than 2 per cent. of the total cost of construction.

Dollfus, being unable to test the antiseptic properties of the new compounds in the direction indicated, has tried one of them, namely, zinc salicylate, with respect to its suitability for use in calico printing and finishing. He reports that it is quite unfitted for use in the latter process, on account of the decided pink colour it imparts to the pastes, and is, moreover, less efficient than sodium bisulphite as a preservative of starch paste and glue size. Further, it is unsuited for preserving solutions of blood albumen and casein, since it partially coagulates these bodies.

Dollfus adds that, with an addition of 1 per cent. of a solution of sodium bisulphite at 17° B. to glue solutions and starch pastes, he has succeeded in keeping the same in good condition for upwards of a month, whereas without such an addition they decompose in the course of a few days.

—E. B.

XIX.—PAPER, PASTEBOARD, Etc.

On the Composition of Woody Matter and the Influence of Alkalis and Calcium Bisulphite on Wood. A. Ihl. Chem. Zeit. 15, 201—202.

WOOD consists of about equal parts of cellulose and lignin. What lignin is cannot at present be decided with certainty. Singer has found in woody matter vanillin, coniferin, wood gum, and another body soluble in water which shows a yellow colouration by hydrochloric acid. The tests with aniline sulphate and with phloroglucinol are well known, and according to the author an alcoholic pyrrhol solution is the most sensitive reagent for woody matter (compare Chem. Zeit. 14, 304 and 438, and this Journal, 1890, 555 and 770). The author has shown that delicate colour reactions exist between phenols and wood in the presence of acids. Alcoholic solutions of oreinol and resoreinol especially, show such reactions on wood in presence of hydrochloric acid. As all these reactions differ from those on vanillin and on coniferin, there must be still other substances contained in woody matter. Now, the author has found that some ethereal oils, such as clove oil, pimento oil, and more especially cinnamon oil, show the same colour reactions as lignin (compare Chem. Zeit. 13, 264, 560, and 831; this Journal, 1889, 421 and 640). Cinnamon oil consists of a carbohydrate and cinnamic aldehyde, and the latter shows almost the same colour reactions as lignin with the following substances:—Pyrrhol, aniline sulphate, phloroglucinol, oreinol, resoreinol, and other phenols, sulphuric acid, urea, lepidine, and antipyrine, and therefore it is very probable that cinnamic aldehyde is contained in woody matter; and this assumption is supported by the fact that the urine of plant-eating animals contains more hippuric acid than that of the carnivora, and it is proved that hippuric acid is secreted when cinnamic acid has been taken as a medicine (compare Beilstein, p. 899). The author therefore draws the conclusion that physiologically cinnamic aldehyde is first converted by oxidation into cinnamic acid and then into hippuric acid. It is not impossible that besides cinnamic aldehyde other derivatives of allylbenzene, such as eugenol, safrol, and anethol, which show similar colour reactions as lignin, are contained in small quantities in woody matter. All these organic compounds are derivatives of the same carbohydrate, viz., allylbenzene, and have the following formulae:—

Allylbenzene	$C_6H_5 \cdot CH:CH \cdot CH_3$
Cinnamic aldehyde . .	$C_6H_5 \cdot CH:CH \cdot COH$
Eugenol	$C_6H_3 \begin{cases} < OH \\ < OCH_3 \\ < C_3H_5 \end{cases}$
Safrol	$C_6H_4 \begin{cases} < O \\ < O > CH_2 \\ < C_3H_5 \end{cases}$
Anethol	$C_6H_4 \begin{cases} < OCH_3 \\ < C_3H_5 \end{cases}$
Coniferyl alcohol . .	$C_6H_3 \begin{cases} < OH \\ < OCH_3 \\ < C_3H_4 \cdot OH \end{cases}$
Vanillin	$C_6H_3 \begin{cases} < OH \\ < OCH_3 \\ < CHO \end{cases}$

It is not likely for cinnamic aldehyde to be present in lignin in a free state, as it cannot be extracted from wood by the usual solvents. But the author ascertained by experiments that also cinnamon itself does not contain free cinnamic aldehyde, and he is of opinion that cinnamon oil, as well as clove, pimento, and saffras oil, are formed only if the several plants are distilled with water containing salt. In cinnamon the cinnamic aldehyde probably forms a compound with a carbohydrate, which compound may perhaps contain still other components, clove oil consists of eugenol and a sesquiterpene, $C_{15}H_{24}$, &c. Probably the aromatic substances of lignin, viz., cinnamic aldehyde, eugenol, vanillin,

&c., form similar compounds with terpenes, resins, camphor, and gum, and perhaps also with cellulose. These compounds are decomposed by boiling with alkalis or acids, especially if great pressure is employed. A partial decomposition already takes place if wood is boiled in water. The author places lignin, because of its composition, amongst the class of the so-called "gum-resins," although resinous substances are only of quite minor importance in lignin. Some balsams and resins show almost the same reactions with phloroglucinol and aniline sulphate as lignin does. But the gummy matters, on the other hand, are of very great importance in lignin, most of the incrusting substances consisting of them. They show a great similarity with arabin, and are found in the products of the sulphite process as well as of the caustic soda process. If sulphite lye which has been used for pine wood is carefully evaporated, a yellowish-brown and transparent resinous substance is obtained, which is described by the author as the calcium salt of the "arabic acids" of the wood. This substance shows similar properties and reactions as gum arabic. These "arabic acids" of the wood are soluble in hot water, and form, with metallic oxides, compounds which are easily soluble in water, but precipitated by alcohol.

Moreover, these arabic acids are comparatively strong acids, and decompose carbonates, sulphites, and sulphides, especially under pressure, a property which is of importance in the explanation of the sulphite process, as the salts of the arabic acids are the chief components of lignin. If wood is boiled under great pressure with caustic soda, the lignin is decomposed. The gummy matters, resins, and phenols are dissolved, and the volatile compounds, *e.g.*, terpene, &c., escape. Cinnamic aldehyde and vanillin polymerise, and coniferin is decomposed. It is well known that sulphurous acid has a decomposing or polymerising effect upon many groups of organic compounds. In the sulphite process it first decomposes lignin, then the free arabic acids decompose the sulphite of lime, hereby forming the calcium salt of the arabic acids, which remains in solution, whilst the free sulphurous acid escapes. The author is of opinion that the sulphite process is, in the main, hereby explained. The terpenes and aldehydes mostly polymerise and escape together with the other volatile aromatic compounds of the woody matter as well as the sulphurous acid, whilst the non-volatile substances, *e.g.*, the resins, are left, parts of which remain as the calcium salt of the resin acids. (See also "Wood Sugar and Wood Gum," this Journal, 1891, 173.)—H. S.

On the Quantitative Determination of Mechanical Wood Pulp in Paper. R. Benedikt and M. Bamberger. *Chem. Zeit.* 15, 221-222.

See under XXIII., page 576.

Celluloid and its Manufacture. Industries, 1891, 10, 571-572.

In France celluloid is made from a solution of camphor and nitro-cellulose in alcohol, whilst in Germany, in addition to the alcohol, ether is employed as a solvent.

The paste formed in this way is gently warmed, and then rolled out into thin sheets, and in this state loses the last portions of its volatile solvents. The product so formed is a brittle, transparent, horny mass, consisting of either an intimate mixture of camphor and pyroxyline or possibly of a chemical compound of these two bodies. H. Bockmann gives the following analyses of two samples of this material:—

	German.	English.
Nitro-cellulose.....	64.89	74.70
Camphor.....	32.80	22.70
Colouring matter.....	2.35	4.51
Total.....	100.00	100.00

The former of these is met with in commerce in rods, whilst the latter occurs in blocks.

The nitro-cellulose used for this manufacture is obtained by nitrating paper, cotton wool, or wood shavings. A mixture of two parts sulphuric acid and one part fuming nitric acid at a temperature not exceeding 22° C. gives the best results. In some works a mixture of 115 parts of sulphuric acid, sp. gr. 1.84, and 93 parts of nitric acid is heated to 80° C., and cotton wool plunged into this bath for a few minutes, and then withdrawn and well washed. This product is entirely soluble in alcohol. Should the nitration be incomplete, a mixture of alcohol and ether will fail to completely dissolve the nitrated cellulose.

Unless the cellulose used has been previously bleached, it is absolutely necessary to perform this operation after nitrating. The nitro-cellulose is disintegrated, washed with carbonate of soda, then with water, and finally transferred to truncated bleaching tubs holding about 10 cubic metres (2,200 gallons). These vats are provided with perforated copper bottoms, through the centre of which pass agitators. The washed nitro-cellulose is added, with three times its volume of water containing 2 per cent. of potassium permanganate; it is left for about an hour, when a fresh quantity of water is added. Then, after standing for half an hour, a strong brine is added, together with some hydrochloric acid. This mixture is allowed to react on the pyroxylin for an hour; then the whole mass is thoroughly washed, first with water and finally with sulphuric acid, to remove all foreign matters.

The pyroxylin thus prepared, when freed from acid, is carefully dried, cut into small fragments by special machinery, mixed with camphor, and reduced in a suitable mill to a fine powder, about 40 per cent. of water being added to prevent the pyroxylin taking fire. The meal obtained is compressed by a hydraulic press into cakes, which are subsequently broken into fragments and transferred to a closed vessel, where they come in contact with from 15 to 35 per cent. of alcohol of 96 per cent. In twenty-four hours a gelatinous mass is obtained, which is then generally spread out by hollow rollers heated internally by steam to keep the temperature of the exterior surface at about 60° C.; this rolling is continued between cylinders more and more closely set together until a sheet is obtained about 12 mm. thick, having the required resistance and consistency.

In order to expel air bubbles from these sheets, heat and a hydraulic press are used, and finally the celluloid is again compressed in the cold into large blocks, which can be easily stored. When the celluloid is sent out into commerce, these blocks are split into leaves, more or less thick, by means of special planes, or by circular saws moistened with steam. After this treatment the cut leaves are placed in ventilated drying rooms, kept at about 90°. At the end of twelve hours the material is dry enough for sale. Crude celluloid is a transparent horny substance of a pale yellowish colour, with a characteristic odour of camphor; its specific gravity varies between 1.25 and 1.45. It is softened by heat, and is then capable of receiving an impression. At 90° C. it becomes very plastic; further heat softens it, and a temperature of 140° C. decomposes it into pyroxyline and camphor aldehyde. At 195° C. the decomposition is instantaneous; the nitro-cellulose inflames and the camphor is vaporised.

Celluloid is readily inflammable and burns with a crackling flame; on blowing, the flame is easily extinguished, but the mass continues to burn, liberating thick vapours of camphor. It is not affected by concussion, and does not detonate even in contact with fulminates. Sulphuric acid decomposes it rapidly on warming; hydrochloric acid has a much slower action. Nitric acid attacks it slowly in the cold, very rapidly when warmed, and soda lye acts similarly. If it is desired to imitate either marble, ivory, or tortoise-shell in celluloid, it must be coloured uniformly or with layers of different tints. In the first case the colouring matter is incorporated with the mixture of pyroxyline and camphor, for which purpose mineral colours are generally employed. In the second case, different tinted celluloids in the gelatinous state are prepared, and then united to form the desired object having a required colour, the harmonious

blending of the colours depending entirely upon the skill of the workmen.

The amount of camphor in a sample of celluloid can be estimated by F. Foerster's process, described in Ber. 23, 2981—2989 (this Journal, 1890, 1159—1160).

On the Action of Nitrosulphuric Acid on Vegetable Fibres.
J. Lifschütz. Ber. 24, 1186—1192.

THE object of the author's experiments has been the complete isolation of cellulose from vegetable fibres, and at the same time to obtain a good yield of it. He finds that the best results are obtained by treating the fibre with a mixture of nitric acid of 25 to 30 per cent. strength and sulphuric acid. The specific gravity of the acid mixture is from 1·34—1·36, and the mixture itself contains 32 per cent. of H_2SO_4 , and 18—20 per cent. of HNO_3 . For the experiments pine wood was used and the following process is recommended. One part of pine wood free from knots and bark was cut into cubes, the sides of which were 10—15 mm., were covered with 10—15 parts of the acid mixture, and heated for 14 to 16 hours. After this time evolution of gas had ceased. The product was taken out whilst still warm and washed, first with cold and then with warm water, and afterwards boiled with dilute solution of soda until the fibres were separated. It was then removed from the brown lye and washed with water and vigorously shaken up with water. After filtering and washing until the filtrate is quite colourless, pure cellulose is obtained which is white and silky in appearance, is perfectly neutral, shows no reaction for lignin, is strong, and easily felted. It contains 1·5—1·8 per cent. of ash and no trace of nitro-cellulose, and the yield of cellulose from this operation is from 38 to 41 per cent. The residual bright yellow acid mixture remained clear on dilution with water. It contained a considerable amount of oxalic acid and smaller quantities of other fatty acids. It reduced Fehling's solution, thus indicating cellulose sulphuric acid. The original amount of sulphuric acid was still present, but the solution was poorer in nitric acid by about the weight of the wood which had been treated in it. In order to convert the cellulose sulphuric acid as much as possible into oxalic acid, this mixture was used for 4—5 other operations, the relative proportions between nitric acid and wood being maintained. The process was conducted as before, except that at each operation the temperature was raised 5° higher than in the preceding one. In this way all the nitric acid was utilised; its action was the same in the last as in the first operation. This acid liquor on standing for 24 hours deposited a considerable amount of oxalic acid crystals. From these processes the average yield of cellulose was 38 to 40 per cent., and of oxalic acid 25 to 30 per cent. on the weight of dry wood used. The remaining acid liquor contains 1·5 to 2 per cent. of oxalic acid, and can be regenerated by the addition of nitric acid, and when necessary some sulphuric acid, and used again for the treatment of wood. The following table shows the results of treating pine wood in the above manner with regenerated acid mixture. 112 kilos. of the mixture of sp. gr. 1·32, containing 32 per cent. of sulphuric acid, 12·5 per cent. nitric acid, and 1·25 per cent. oxalic acid, was caused to react upon:—

I.	7·0 kilos. of pine wood containing 34·0 per cent. H_2O				
II.	5·0 " " "	30·3	"	"	"
III.	4·5 " " "	30·0	"	"	"

	Kilos. Dry Wood.*	Weight of Resulting.	Oxalic Acid.		Cellulose dried at 100° from 100 Parts of Wood.
			Calculated on 100 Parts of Wood.	Calculated on 100 Parts of missing Cellulose.†	
I.	4·62	1·39	32·2	152	38·80
II.	3·48	0·87	25·0	132	40·87
III.	3·15	0·08	30·4	127	36·00

* The former figures are calculated to dry wood in the table.

† Pine wood, after deducting 12 per cent. of water, contains about 60 per cent. of cellulose.

The gases given off during the reaction contain solely N_2O , NO , and NO_2 , with a small quantity of carbonic acid, and can therefore be easily converted into nitric acid.

—W. M.

New Material for the Manufacture of Paper. Moniteur des Produits Chimiques, May 10, 1891.

FOR a long time past search has been made in all civilised countries for a substitute for rags, which was formerly the only material known from which paper could be manufactured. The consumption of paper having taken formidable proportions, the store of rags has sensibly diminished in all parts of Europe. Attempts have been made to substitute for rags such substances as wood-paste, straw, alfa, &c., but these, with the exception perhaps of alfa, have failed to produce any but inferior kinds of paper.

The manufacture of alfa for this purpose has already assumed considerable proportions in Algeria, and now another grass, related to alfa, has been discovered to possess qualities which may very advantageously be employed in the manufacture of paper. This plant is *diss*, the *Ampelodesmos tenax* of botanists.

MM. Caselmann and Wetterlé, of Souk-Ahras, have placed before the prefecture of Constantine a request for a patent relating to a process, invented by them, by which paper-paste of a great delicacy, possessing the same qualities as alfa, can be produced from *diss*. The advantage of the new material is that, owing to the simplicity of the processes to be employed, it can be manufactured in Algeria at half the price of alfa-paste manufactured in France or in England.

The abundance of *diss* in the north of Africa would easily permit the production of from 50,000 to 100,000 tons per annum. *Diss* is found in Algeria in the Tell, the mountains, where it grows without being cultivated, whilst alfa is found on the high plateaux—that is to say, at a greater distance from the sea-ports—and in regions very much more difficult to deal with, on account of the lack of water and of means of transport. *Diss* occupies in Algeria an area 150 kilometres in extent, parallel to the sea. It can easily be mown with a scythe; alfa, on the other hand, requires to be picked, and the cost of this manual labour is much more considerable. Various attempts have been made in France and in England to withdraw the cellulose part of the *diss*, but hitherto without success, *diss*, once dry, becoming hard and brittle, its resinous silicious parenchyma offering a great resistance to chemical agents. The process of Caselmann and Wetterlé allows the *diss* to be used when it is freshly mown, by means of chemical products which only cost half of those which are used for the manipulation of wood, straw, or alfa. The amount of cellulose produced by *diss* is much greater than that by alfa.

PATENTS.

Improvements in the Manufacture of Waterproof Boards, Paper, and such like Materials. C. Weygang, London. Eng. Pat. 3004, February 25, 1890. 8d.

See under XIII., page 556.

Improvements in Glazing Paper and in Machinery or Apparatus therefor. J. Robertson, Pollokshaws. Eng. Pat. 4360, March 20, 1890. 6d.

THE object of this invention is to produce a glaze or finish on that side of the paper left rough in the process of manufacture on a "Yankee" machine. It is attained by the addition of extra cotton rolls fitted outside the main glazing cylinder.—E. J. B.

Improved Processes for the Nitration and the Denitration of Cellulose and for Regaining the Acids Employed and Apparatus Employed in connection therewith. H. D. Chardonnet, Paris, France. Eng. Pat. 5376, April 8, 1890. 8d.

THE nitration is effected in the ordinary way. The nitro-cellulose and mixture of acids are placed in a centrifugal machine, by which means about three-fourths of the acids are recovered and may be again used after being strengthened with fresh acids. Or it may be heated and the nitric acid which distils may be collected, while the residual sulphuric is further heated to free it from water.

The acids remaining in the nitro-cellulose are removed by washing. The washings are neutralised with lime, and the solution of nitrate of lime is decomposed with sulphate of soda. The nitrate of soda thus obtained is used for the preparation of nitric acid. The nitro-cellulose obtained is bleached with a solution of bleaching powder.

Denitration is effected by means of warm nitric acid, alkaline sulphides, or sulpho-carbonates.—E. J. B.

Improvements in and relating to the Treatment of Paper-making Fibre Materials. J. Johnston and Peter Culter, Aberdeen, and G. Johnston, Wells. Eng. Pat. 6644, April 30, 1890. 8d.

WHEN the esparto or other fibrous material has been boiled and partially washed, the boiler is filled with cold water and a current of air is forced in under the perforated bottom. This agitates the material completely, removes residual alkali, and at the same time oxidises the fibres. Drawings showing the necessary appliances accompany the specification.—F. J. B.

Improvements in Machinery or Apparatus for Coating the Surface of Paper or other Flexible Material with Gum or other Adhesive Substances of the like kind, and for Sizing, Staining, and the like, or Varnishing such Material. W. B. Silverlock, London. Eng. Pat. 6735, May 1, 1890. 8d.

THE sheets of paper, &c. to be treated are placed upon a continuously revolving horizontal cylinder, having openings provided with gripping strips or bands and with pins or studs, by which the sheets are carried round the cylinder, and automatically removed after being gummed, &c. Below the cylinder a moveable vessel containing gum or other adhesive liquid is attached in such a way as to be easily removed and substituted by others when required. This vessel (which may be kept warm by a water-bath, &c.), contains a slowly revolving roller or some similar arrangement, covered with a soft material or a brush which coats the sheets of paper, &c. with the liquid as they are being carried round upon the cylinder. By bars, pads or scrapers, &c., fitted parallel with the roller, the coating is equalised upon the sheets, which are then automatically removed from the cylinder to endless travelling bands. The vessels and rollers being adjustable and removable, different ones can in turn be used for gumming, sizing, staining, varnishing, &c.—H. S.

Improvements in Coating Iron, Steel, or other Metals or Materials with Portland or other Cement. C. Kellner, Vienna, Austria. Eng. Pat. 6932, May 6, 1890. 6d.

ONE hundred pounds of blue slate finely ground are mixed with 30 to 40 lb. of silicate of soda at 100° Tw., and applied to the surface to be protected in a layer about $\frac{1}{4}$ in. thick. A second coating of similar thickness and composed of equal parts of ground slate and Portland cement made into a paste with water is then applied, and the protecting layer is completed by one of Roman, or preferably Portland, cement alone.

The treatment is recommended for lining vessels or tanks made of brickwork, such as "stuff chests" and rag engines used in the manufacture of paper, where heat, acids, or alkalis have to be resisted (see this Journal, 1891, 380). For protection against acids it is, however, better to use for

the second coating a mixture consisting of equal parts of ground glass, ground slate, and Portland cement, and to dispense with the third coating.—B. B.

Improved Apparatus for Separating or Disintegrating Fibres in the Manufacture of Paper Pulp. C. Kellner, Vienna, Austria. Eng. Pat. 6993, May 6, 1890. 6d.

THE patentee has constructed a machine consisting of a horizontal roller toothed externally and surrounded by an internally toothed cylinder. When the roller revolves these two sets of rings of teeth thoroughly rub and bruise the fibres, but do not cut them. The evenness of the pulp and the quality of the paper are thus improved. Before placing the fibres into this apparatus, they have to be digested in the usual manner and mixed with a suitable quantity of water.—H. S.

Registering Apparatus for Paper-Making Machines. C. J. Richardson, Gateshead-on-Tyne. Eng. Pat. 7598, May 15, 1890. 8d.

THE apparatus consists of two drums, one of which revolves ten times as fast as the other. They are driven by the paper machine itself at any convenient place. One revolution of the slow drum corresponds to a definite length of paper.—E. J. B.

Improvements in the Manufacture of Paper Pulp. J. F. N. B. Simons, Stratford, and S. Smith, Walthamstow. Eng. Pat. 10,259, July 2, 1890. 4d.

THE object of this invention is to render bamboo more suitable as a paper-making material. This is brought about by detaching the outer skin of the bamboo to a depth of about one-sixteenth inch. The part so removed is rejected and the residue is treated in the usual way.

—E. J. B.

Improvements in or Relating to the Treatment of Vegetable Parchment and the like. A. Wilbaux, Brussels, Belgium. Eng. Pat. 17,268, October 28, 1890. 4d.

THIS invention consists in rendering vegetable parchment non-hygroscopic, and at the same time adhesive by applying to it, either on one or on both sides, layers of oil or oil colour of uniform consistency and softness, or of varnish and the like. When these layers are dry the material may be ornamented by printing, embossing, stamping, and then varnished and glazed in an oven, or otherwise treated to improve its quality and appearance. Thus treated it is said to be capable of being used in many ways not before contemplated, e.g., in the leather, carriage building, book-binding and various other trades.—H. S.

Improvements in Purifying Wood-Pulp and in Apparatus therefor. J. C. Juell and E. Ryan, Fredrikstad, Norway. Eng. Pat. 2349, February 9, 1891. 6d.

THE apparatus consists of a centrifugal machine into which the liquid pulp is fed. Any heavy impurities contained in the pulp are separated from the lighter pulp.—E. J. B.

Improvements in and relating to the Manufacture of Distinctive Paper for Bonds, Notes, Checks, and other Securities. J. Macdonough, New York, U.S.A. Eng. Pat. 3791, March 3, 1891. 6d.

THE inventor incorporates with the pulp before it reaches the paper machine a number of "planets" or pieces of paper punched from sheets of manufactured paper. These may be of any size or colour.—E. J. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Constitution of Nicotine. F. Blan. Ber. **24**, 326—329.
(Compare Pinner and Wolfenstein, this Journal, 1891, 381.)

THE fact that the dipiperidyl (hexahydronicotine) prepared by Liebrecht (Ber. **19**, 2587) from nicotine, boils at a relatively low temperature (250°—252°) compared with the *aa*-dipiperidyl (boiling point 259°) obtained by the author from *aa*-dipyridyl (Monatsh. 1889, 294) is contrary to expectation, since, in all probability, the *aa*-compound boils at a lower temperature than any of the six isomeric dipiperidyls theoretically capable of existence. The author has prepared the *ab*-dipiperidyl from metaphenylenediamine, as described by Skraup and Vortmann; it boils at 295.5°—296.5° (corr.), and on reduction, first with sodium and alcohol, and then with sodium and amyl alcohol, it is converted into *ab*-dipiperidyl. This compound boils at 268°—270° (corr.), melts at about 30°, and is hygroscopic; the hydrochloride and the platinohydrochloride are readily soluble in water, but more sparingly in alcohol; the aurochloride crystallises well and melts at 202° with decomposition. As Liebrecht's dipiperidyl from nicotine is a liquid, and its aurochloride melts at 131—132°, the two bases are certainly not identical.

From a study of the boiling points of the known dipiperidyls and dipiperidyls, it seems highly probable that the as yet unknown *β*-dipiperidyls, namely, the *ββ*- and the *βγ*-derivatives will boil at a higher temperature than the *ab*-compound; as the latter boils at a higher temperature than the *aa*-compound, it seems probable that Liebrecht's hexahydronicotine, which boils at a lower temperature, is not really a dipiperidyl, and consequently that nicotine is not a dipiperidyl derivative.

Further experiments on the constitution of nicotine are in progress.—F. S. K.

Digitonin and Digitogenin. H. Kiliani. Ber. **24**, 339—347.

IN the present paper the author describes the preparation and properties of pure digitonin, one of the glucosides contained in commercial digitalin (this Journal, 1890, 820).

Digitonin crystallises very readily from 85 per cent. alcohol (sp. gr. 0.831 at 20°), but from stronger alcohol it separates in an amorphous condition; from weaker alcohol it is not deposited so completely, and generally in an amorphous state. As the percentage of digitonin in commercial digitalin (pur. pulv.) is variable, it is advisable to make several small experiments in order to ascertain what quantity of 85 per cent. alcohol gives the best results. In the case of a sample of digitalin obtained from Boehringer and Sons, of Waldhof, it was found advantageous to employ 4 parts of alcohol to 1 part of the crude material; after heating from 50°—60° to ensure complete solution, and then allowing to cool slowly (without previously filtering from a small quantity of a voluminous insoluble substance), the digitonin is deposited in crystals, and after about 12 hours crystallisation is at an end. The crystals are then separated by filtration, washed with 85 per cent. alcohol, and dried: the yield of the crude crystalline product is from 43 to 45 per cent., but by a rather complicated process an additional 6 to 8 per cent. can be obtained from the mother-liquors. For further purification the glucoside is dissolved in 12 parts of boiling 85 per cent. alcohol, the solution heated for two minutes with animal charcoal, filtered, and then allowed to cool slowly, when compact crystals of the pure compound are deposited. The weight of the first crop of crystals is only about 45 per cent. of the crude product, but further quantities can be obtained by concentrating the mother-liquors. It may be remarked, however, that spontaneous evaporation usually gives an amorphous product, and also that when the solution is not going to be filtered, only 10 parts of alcohol should be taken to dissolve 1 part of the glucoside.

Pure digitonin dried at 100° has the composition—

It softens at 225°, and gradually melts and turns yellow as the temperature rises to 235°. It is levo-rotatory, a 2.8 per cent. solution in 75 per cent. acetic acid having approximately the rotatory power $[\alpha]_D = -50^\circ$; digitonin and its derivatives have no action on the heart. The crystalline compound is only sparingly soluble in cold water, but much more readily on warming, the solution showing an opalescence similar to that observed in the case of inulin and glycogen. It gives with concentrated sulphuric acid a reddish colouration, which is rendered more intense on the addition of a drop of bromine-water, and when heated with dilute hydrochloric acid as previously described (*loc. cit.*) it yields almost the theoretical quantities of dextrose, galactose, and digitogenin, $C_{15}H_{21}O_9$. It does not yield either methyl or ethyl iodide when heated with hydriodic acid and amorphous phosphorus. When boiled with acetic anhydride and sodium acetate it is converted into a colourless, crystalline, acetyl-derivative which melts at 178° and has the composition $C_{13}H_{20}O_3 \cdot CO_2CH_3$; this compound is *acetyldigitogenin*, and its formation seems to indicate that digitonin is a glucoside of milk-sugar.

When digitonin (1 part) is oxidised with chromic acid (1.4 parts) in acetic acid solution at the ordinary temperature it yields, amongst other products, a monobasic acid of the composition $C_{11}H_{12}O_6$, which the authors name *digitogenic acid*. This substance melts at 146°—150°, has a very bitter taste, and is insoluble in water but readily soluble in chloroform and hot glacial acetic acid. On oxidising digitogenic acid with an alkaline solution of potassium permanganate it yields *oxydigitogenic acid*, $C_{10}H_{10}O_6$, and *digitic acid*, $C_{10}H_{10}O_4$. Both these acids are monobasic; the former melts at about 250°, and is very sparingly soluble in all ordinary solvents, whereas the latter melts at 192°, and is moderately easily soluble in alcohol, chloroform, and glacial acetic acid.—F. S. K.

Cytisine. A. Partheil. Ber. **24**, 634—640.

THE author confirms the formula $C_{11}H_{11}N_3O$ which he had previously (this Journal, 1891, 63, 383) established for cytisine, and shows that the formula $C_{11}H_{10}N_3O$ proposed by Plugge and v. d. Moor (Ann. Chem. Pharm. **229**, 48) is incorrect.

Cytisine crystallises from alcohol in large, odorless, prismatic crystals, free from water. Its melting point is 152—153°C. The presence of methoxyl in the cytisine molecule could not be confirmed. Cytisine is mono- and di-basic, and furnishes two series of salts. *Cytisine hydrobromide*, $C_{11}H_{11}N_3O \cdot HBr$; *hydriodide*, $C_{11}H_{11}N_3O \cdot HI$; *nitrate*, $C_{11}H_{11}N_3O \cdot HNO_3$, and *sulphate*, $(C_{11}H_{11}N_3O)_2 \cdot H_2SO_4$, crystallise well, and are obtained by neutralising the base with the respective acids. The identity of Gerrard's *ulexine* (from *Ulex europaeus*) with cytisine was proved by comparing the two bases and their respective derivatives. Ulexine may be prepared by the following process:—The coarsely-powdered seeds of *Ulex europaeus* are extracted with alcohol acidified with acetic acid. The solution is distilled to remove the alcohol, and the residue is dissolved in hot water and filtered to separate oil and resin. The liquid is precipitated with acetate of lead, filtered, and the filtrate is mixed with an excess of soda solution and repeatedly extracted with chloroform. The chloroform extract on evaporation yields crude ulexine, which may be purified by repeated crystallisation from water or alcohol. The yield of ulexine is about 1 per cent. *Cytisine methyl iodide* forms fine white needles. *Cytisine ethyl iodide* forms colourless crystals. Cytisine methyl iodide, when heated with a 30 per cent. solution of potash, yields the corresponding base, which may be extracted by chloroform. This base gives a reddish-brown precipitate with bismuth potassium iodide, and yields a sparingly soluble platinum salt crystallising in golden yellow leaves. An alkaline solution of potassium permanganate liberates ammonia from cytisine, and substituted ammonias from iodo-alkyl derivatives of cytisine. The author is continuing his researches (see next page).—H. T. P.

Alcoholates. J. W. Brühl and H. Biltz. Ber. **24**, 649—650.

ALCOHOLATES of sodium may be readily prepared from methyl, ethyl, or others of the lower alcohols by dissolving the anhydrous alcohol in toluene or xylene, and treating the solution at 170—180° C. with the theoretical amount of metallic sodium. A considerable length of time is necessary for the complete solution of the sodium, because the metal becomes covered with a protecting crust of alcoholate, but the latter is finally obtained as a snow-white mass suspended in the hydrocarbon, and quite free from alcohol.—H. T. P.

Constitution of Leucin. E. Schulze and A. Likiernik. Ber. **24**, 669—673.

THE authors have succeeded in proving that inactive leucin, obtained by heating the active modification with baryta at 160°, is identical with α -amidoisobutyl acetic acid prepared synthetically from isovaleraldehyde; the two compounds have the same solubility in water, they both yield the same product, namely, active leucin, when submitted to the action of *Penicillium glaucum*, and they are converted into one and the same hydroxyacaproic acid on treatment with nitrous acid.

The inactive leucin employed in these experiments was obtained from the vegetable albuminoid *Conglutin*; since it is possible that different animal and vegetable products may yield different kinds of leucin, the above statement must be held to refer only to the compound obtained from *Conglutin* and to those preparations with which it is identical in properties.—F. S. K.

Cytisine. K. Buehka and A. Magalhães. Ber. **24**, 674—680.

A FURTHER investigation of the poisonous substance cytisine (compare this Journal, 1891, 63, 383 and 567) has shown that its composition is expressed by the formula $C_{11}H_{13}N_2O$; it forms two crystalline hydrochlorides, having the composition $C_{11}H_{13}N_2O \cdot HCl + H_2O$ and $C_{11}H_{13}N_2O \cdot 2HCl + 2\frac{1}{2}H_2O$ respectively, and two platinumchlorides, namely—

and—

but only one aurochloride of the composition—

Cytisine combines with methyl iodide to form *methyl cytisine hydriodide*, $C_{11}H_{13}N_2O \cdot CH_3 \cdot HI$; this compound melts at 253.5°, and when treated with alkalis it is converted into *methylcytisine*, $C_{11}H_{13}N_2O \cdot CH_3$, a colourless crystalline substance melting at 245°. The *hydrochloride* of methylcytisine melts at 249—250°, and has the composition $C_{11}H_{13}N_2O \cdot CH_3 \cdot 2HCl + 1\frac{1}{2}H_2O$; the *aurochloride*, $C_{11}H_{13}N_2O \cdot CH_3 \cdot HAuCl_4$, is a yellow crystalline compound melting at 196°.

Acetylcytisine, $C_{11}H_{13}N_2O \cdot CO \cdot CH_3$, obtained by heating cytisine with acetic anhydride, forms colourless crystals and melts at 208°; *nitrosoacetylcytisine*, $C_{11}H_{13}N_2O \cdot NO$, crystallises in colourless needles and melts at 174°.

Ulexine, prepared from the seeds of *Ulex europaeus*, is probably identical with cytisine; its aurochloride melts at 205°, and its acetyl derivative at 202—204°, the corresponding cytisine-derivatives melting at 213 and 208 respectively. These slight differences in the melting points may be due to impurities; as, however, the compound obtained from ulexine by the action of methyl iodide melts at 290°, whilst that prepared from cytisine in like manner melts at 253.5°, the question of the identity of the two bases is left undecided, although further investigation will probably answer it in the affirmative. (See Partheil, Ber. **24**, 634—640, preceding pages.)—F. S. K.

Anhydro-geraniol: Olefine Terpenes, a new Class of Terpenes; and Benzene Ring Formation. F. W. Semmler. Ber. **24**, 682—685.

THE author has previously shown (this Journal, 1890, 889, 1145; 1891, 269, 382) that ethereal oils contain open-chain compounds of the formula $C_{10}H_{18}O$, $C_{10}H_{16}O$, or $C_{10}H_{14}O$, which, on dehydration either retain their open character or are converted into benzene derivatives. Geraniol belongs to the former class. The complete dehydration of geraniol by means of potassium bisulphate and sodium results in the production of a hydrocarbon, *anhydro-geraniol*, possessed of the following properties: Boiling point, 172—176° C.; specific gravity at 20° C., 0.8232; n_D^{20} , 1.4835 at 20° C. Analysis shows it to have the formula $C_{10}H_{16}$. Physically, anhydro-geraniol differs from the terpenes, which have a density of 0.84—0.86. Its molecular refraction calculated by the formula $\frac{(n^2 - 1) \cdot V}{(n^2 + 2) \cdot d}$ is 47.23.

A body of the formula $C_{10}H_{16}$, with three double carbon linkings, would have a theoretical molecular refraction of 47.12, which agrees very well with the number observed. Anhydro-geraniol, therefore, cannot be a benzene derivative, and this is confirmed by its chemical behaviour. On reduction it yields a body of the formula $C_{10}H_{22}$, and with bromine it forms the substance $C_{10}H_{16}Br_2$. The author proposes to name hydrocarbons of this type *olefine terpenes*. They have been obtained from coriandrol, linalool, &c.

The occurrence of benzene derivatives in plants may be explained on the assumption that they are produced by the dehydration of open-chain compounds. It is, therefore, well to consider the conditions which must be fulfilled in order that such an action may take place. 1. Only aldehydes are suitable. 2. The aldehyde oxygen must not be able to take two hydrogen atoms from the adjacent carbon atoms to form water, i.e., the grouping must be as follows:—

3. The fifth carbon atom, reckoning from the aldehyde carbon, must be united to two hydrogen atoms, which may subsequently form water with the aldehyde oxygen. From this it follows that one hydrogen atom of the benzene ring formed under the above conditions must always remain as such. Calling the carbon to which this particular hydrogen atom is attached 6, the author prefers to designate that carbon atom of the benzene ring as 1, to which is joined some fatty side-chain, generally C_3H_5 . If this theory be correct, no substituted benzene derived from a vegetable organism should possess the structure 1:2:6. The position 6 should always be unsubstituted. All vegetable benzene derivatives hitherto examined by the author have conformed to this requirement. Similar but more complicated considerations may be deduced regarding terpenes, i.e., hydrogenised benzene derivatives. The author is continuing his researches.—H. T. P.

Sparteine. E. R. Ahrens. Ber. **24**, 1095—1097.

SPARTEINE on oxidation yields a base $C_{13}H_{21}N_2O$ *Oxy-sparteine*, which can be extracted from the product of the reaction by means of chloroform. After distilling off the solvent, the base remains as a thick yellow-brown oil which can be obtained in a crystalline condition by converting it into the platinum double chloride and decomposing the latter by sulphuretted hydrogen and caustic soda successively. Thus purified it forms hygroscopic white needles, melting at 83—84°, readily soluble in water, alcohol, ether, and chloroform; the solutions have a strongly alkaline reaction. The hydrochloride of the base forms readily soluble needles having the composition $C_{13}H_{21}N_2O \cdot 2HCl \cdot (2)H_2O$ which at 48—50° melt in their water of crystallisation. The hydrobromide crystallises in rhombohedra, whilst the sulphate forms readily soluble needles. Oxy-sparteine forms two platinum double chlorides—

and—

of which the latter is the more soluble. They both form clear glittering crystals which became opaque when dried over sulphuric acid, but still retain one molecule of water of crystallisation. They melt with decomposition at 209° C. and 221°–223° C. respectively. The gold double chloride, $C_{15}H_{24}N_2O_5 \cdot HCl \cdot AuCl_3$, can be recrystallised from water, forming glittering plates or needles which decompose gradually on heating. The mercuric double chloride melts at 57°–58° C., the picrate at 176°–178° C., but both soften before the melting point is reached.

Analytical data point to the correctness of the above formulae.—C. A. K.

The Formation of Nitrogenous Organic Bases by the Decomposition of Albumen in Plants. E. Schulze. Ber. **24**, 1098–1101.

THE shoots of *Lupinus luteus*, *Soja hispida*, and *Cucurbita pepo*, after they have been cultivated for from 12–14 days in the dark, when extracted with water yield (after the removal of the albumen) precipitates when treated with phosphotungstic acid. These precipitates are decomposed by lime-water with the formation of organic bases. The base obtained both from *Lupinus* and *Cucurbita* has been shown by the author to have the formula $C_6H_{11}N_4O_5$, and has been named *Arginine* (Ber. **19**, 1177). It only occurs to a small extent in the latter plant, but in such great quantity in the former that it must have been formed at the cost of the albuminoid substances contained. *Soja hispida* contains either the same or a similar base.

That the arginine is really formed as a decomposition product of the albuminoid matter contained in the seeds of *Lupina* is shown by a special experiment, full details of which are given.

By the action of hydrochloric acid and zinc chloride upon casein E. Drechsel obtained a basic substance, *Lysatine*, $C_6H_{13}N_3O_5$, together with ammonia and amidic acids (Ber. **23**, 3098), which differs from *Arginine* as regards its empirical formula only in having one atom of hydrogen and one atom of nitrogen more than the latter.

—C. A. K.

Shikimic Acid. J. F. Eykman. Ber. **24**, 1278–1303.

SHIKIMIC acid is the name given to a non-poisonous acid occurring in the fruit of *Illicium religiosum* (Jap. Shikimi), to the extent of several per cent. Its isolation has been previously described by the author (Rec. d. trav. Chem. de Pays Bas. 1885, 32) who has also detected its presence in the fruit of the real Chinese star-anise.

The acid forms a crystalline powder consisting of fine needles which melt at 184°, and have a specific gravity of 1.599 at 14° C. Its solubility in water is about 18:100; in absolute alcohol, ether, chloroform, and benzene it is almost insoluble. It decomposes carbonates readily, prevents the precipitation of several metallic oxides by bases, does not reduce alkaline, silver or copper solutions, but decolourises potassium permanganate solution readily in presence of sodium carbonate. Analyses of the free acid and of its calcium and silver salts, as well as a determination of the molecular weight by the cryoscopic method point to the formula $C_7H_{10}O_5$, and to the mono-basidity of the acid. The acid is strongly optically active, the specific rotatory power being $[\alpha]_D = -246.3^\circ$; the rotatory power of the ammonium salt is still greater. This salt forms well-defined rhombic crystals, readily soluble in water. Of the other salts of the acid, all of which are also readily soluble in water, those of the fixed alkalis could only be got in an amorphous condition. The calcium salt when subjected to dry distillation forms phenol, with evolution of carbon dioxide and water; catechol appears also to be formed in the reaction.

Acetic anhydride and its homologues react with shikimic acid with the formation of tri-acetyl and similar compounds, thus pointing to the presence of three hydroxy-groups in the acid. The specific rotatory powers of these esters, which have only been obtained in an amorphous condition, is greater than that of the free acid, and increases with the number of CH_3 groups contained in the acid radicle. Heated with hydrochloric acid shikimic acid yields

1:4 hydroxybenzoic acid, together with other products that have not been identified. On reduction with sodium amalgam a dihydro-acid, $C_7H_{12}O_5$, results which was obtained both in an amorphous and in a crystalline state, the former differing from the latter in the ease with which it is decomposed by hydrochloric acid with the formation of benzoic acid. With bromine a crystalline dibrom-shikimic acid, $C_7H_{10}Br_2O_5$, is formed, which melts with decomposition at 188°; its aqueous solution when evaporated, or better when treated with silver oxide, loses hydrobromic acid to form a lactone, $C_7H_8BrO_5$, which crystallises from water in hexagonal needles melting at 235°. Treated with baryta water the dibromolactone is converted into a dihydroxy acid, $C_7H_{10}(OH)_2O_5$, which begins to melt at 156°, and is fairly soluble in cold water, readily in hot; it has no appreciable rotatory power. A comparison of the relative properties of quinic acid, $C_7H_{12}O_6$, quinide, $C_7H_{10}O_6$ (obtained by the removal of a molecule of water from quinic acid), and shikimic acid follows, the paper concluding with a discussion of the constitutional formula of shikimic acid. Its decompositions point to its being a trihydroxytetrahydrobenzene monocarboxylic acid, having probably the following formula—

but the position of two of the three hydroxyl groups requires further confirmation.

Tables giving the rotatory power, electrical conductivity and crystallographic measurements of the acid and of its derivatives are given in detail.—C. A. K.

Nicotine. A. Pinner and R. Wolfenstein. Ber. **24**, 1373–1377.

By the action of benzoyl chloride on nicotine, Will obtained a crystalline compound to which he assigned the formula $C_{10}H_{14}N_2 \cdot 2C_6H_5 \cdot CO \cdot Cl$. In repeating this experiment the authors obtained a basic hydrochloride of nicotine $C_{10}H_{14}N_2 \cdot HCl$ mixed with a little benzoate, the formation of which salts is traced to the decomposition of the benzoyl chloride into benzoic acid and hydrochloric acid by the moisture of the air. The nicotine was dissolved in anhydrous ether, and in one experiment in which the mixture was kept in a closed vessel over strong sulphuric acid, i.e., in a perfectly dry atmosphere, no crystalline product was formed.

Although no compound of nicotine and benzoyl chloride could be obtained according to the method described by Will, the two substances do combine when heated on the water-bath for about 20 minutes to form a thick colourless syrup, hardly attacked by caustic soda in the cold but which behaves as a mon-acid base, being readily soluble in dilute hydrochloric acid. The base could not be obtained in a crystalline condition, but an analysis of the picrate, the only salt that could be obtained crystalline, points to the formula $C_{10}H_{14}N_2 \cdot C_6H_5 \cdot CO \cdot Cl$ for the base. This salt is scarcely soluble in water and melts at 139° C.—C. A. K.

What is Aristol, and how is it Manufactured? G. M. Beringer. Am. Jour. Pharm. April, 1891; Pharm. J. 1891, 1135–1137.

A FORMULA based upon the experiments of Messinger and Vortmann would be—

	Grms.
Thymol	15
Soda	20
Iodine	50.8
Potassium iodide	66.4

The thymol and soda are dissolved in 250 cc. water. The iodine and potassium iodide in 1,000 cc., and gradually added to the first solution, continually stirring. The precipitate is collected, washed, and dried. The precipitate obtained by this formula was at first of a purple-brown colour, but while drying gradually became lighter in colour, until when dry it was of the same yellow-red colour as the commercial article. The filter on which the precipitate was collected and dried was stained with iodine. The filtrate gave no indication of free iodine, and a portion acidulated and extracted with ether yielded no thymol, showing that the reaction was complete. It is not believed that this is the process adopted by the manufacturers, as it requires the use of a large amount of iodide of potassium and iodine, the greater portion of the latter being lost in the drying of the precipitate.

The following formula is offered as an economical process.—

	Grams.
Thymol	15
Soda	20
Iodine	6.35
Potassium iodide	8.3
Solution of chlorinated soda, a sufficient quantity.	

The thymol and soda are dissolved in 250 cc. of water. The iodine and iodide of potassium are also dissolved in 250 cc. of water and the two solutions mixed, resulting in an opalescent solution with a distinct green tint, the slight precipitate first formed being redissolved. Solution of chlorinated soda is now added gradually while stirring, until no further precipitation is produced, and a slight excess is indicated by the odour. About 650 to 700 cc. will be required. The precipitate, a light red-brown in colour, is collected, washed, and dried by spreading on bibulous paper in a suitable room where it can be protected from the light, at a temperature not exceeding 50° C. The filtrate showed the absence of iodides in any quantity, and a portion acidified and extracted with ether yielded no thymol. The yield by this and the preceding formula was about 29 grms., corresponding in colour, melting point, and solubilities, with the aristol in the market, and closely approximating the theoretical yield 29.285 grms. calculated from the formula $C_{10}H_{14}O \cdot 2 H_2O$.

The thymol used in this formula must be free from essential oil of thymene, or there is produced some iodoform in the reaction, which remains as a contamination of the finished product. As most of the commercial thymol contains a small portion of hydrocarbon it must be first purified, which is easily accomplished by percolating the powdered thymol with a small quantity of purified petroleum spirit, which dissolves of course a portion of the thymol as well as the thymene, but it can be recovered by evaporation of the solvent and used for other purposes. The solution of chlorinated soda used should contain no excess of chlorinated lime, and in its preparation for this purpose it is advisable to use an excess of sodium carbonate, as an excess of this latter salt does not affect the product.

In the "Repertoire de Pharmacie," 1890, 355, M. Louis Boule turns the following formula for the preparation of aristol. Crystallised thymol, caustic soda and potassium iodide each 5 grms., dissolved in 50 cc. of water and then poured into 250 cc. concentrated solution hypochlorite of soda. It will be observed on calculating the quantities used that there is an insubstantial amount of iodine supplied by the potassium iodide to furnish a product of the above composition. In the absence of sufficient iodine a certain amount of the thymol combines with the chlorine. Upon adding solution of chlorinated soda to an alkaline thymate solution, there is precipitated a compound of a pinkish tint soluble in ether, alcohol, and chloroform, and precipitated from its alcoholic solution by water. The filtrate from this precipitate yields but a slight trace of thymol upon acidifying and extracting with a solvent. A similar product is obtained by passing chlorine into an alkaline solution of thymol until there is a decided excess of chlorine.

These are evidently chlorine compounds with thymol, most likely a dithymol compound, and worthy of further investigation.

Formosa Camphor. Report by Consul Warren on the Trade of Taiwan (Formosa). Pharm. J. 1891, 1137.

Formosa camphor is obtained from the *Laurus camphora*, immense forests of which extend over most of the lower ranges of hills in the island, extending up the lower slopes of the mountains inhabited by the savage tribes. Many of these forests have not been touched, and the statement that the camphor supplies in South Formosa are becoming exhausted, applies only to those districts which are purely Chinese. The supply from other parts is practically inexhaustible. Even in purely Chinese districts it is only at certain places that the supply is falling off in consequence of the reckless manner in which the trees have been destroyed, partly for the sake of the timber and camphor, and partly, no doubt, simply to clear the ground for cultivation.

It has been often stated that the method of obtaining crude camphor in Formosa is by steeping the chopped branches in water, and boiling until the camphor begins to adhere to the stick used for stirring, when the liquor is strained, and by standing the camphor concretes. By this method it does not necessarily follow that the tree is destroyed, in fact with a little care there is no need that it should be. But although this method may have been in use in former days, it certainly is not now. On the contrary, the writer was assured by several natives engaged in the trade, whom he had questioned on the subject, that the yield of camphor from the branches was too small to repay the labour of extraction.

The method in general use now is as follows: The camphor expert selects a tree and scrapes into the trunk in different places, using an instrument somewhat resembling a rake, with the view of ascertaining whether it contains sufficient camphor to repay the labour of extraction. A tree is said not to be worth anything for camphor purposes until it is 50 years old, and the yield is very unequal; sometimes one side only of the tree contains enough camphor to satisfy the expert, and in this case that side alone is attacked. The trunk is scraped to as great a height as the workmen can conveniently reach, and the scrapings are pounded up and boiled with water in an iron vessel over which an earthenware jar, specially made for the purpose, is inverted. The camphor sublimes and condenses on the jar, which is removed from time to time, scraped, and replaced. The root of the tree and the trunk, for some eight feet up, contain, as a rule, the greatest quantity of camphor. If the scrapings from the trunk yield well, the chipping is continued until in the end the tree falls. The roots are then grubbed up as it is certain they will give a proportionately good return. If, however, the scrapings do not turn out well, the tree is abandoned, and work is commenced on another. No attempt is made to extract camphor from the fallen trunk or from the branches. In some cases the trunk is sawn up into timber, but this depends on the locality; from many districts, owing to absence of roads, timber would not pay for its transport.

It is impossible to imagine a more wasteful method of procedure, and it is fortunate that the camphor forests of Formosa are practically inexhaustible.

The quantity of camphor produced depends, of course, on the amount of labour employed in the business. Ten of the iron pots mentioned above and their accompanying jars make up what is called a "set," and are worked by four men. One set will produce about 65 lb. in 10 days, or, say, $1\frac{1}{2}$ cwt. a month, but this only under the most favourable circumstances, a fair average is about $1\frac{1}{4}$ cwt.

Recently a great change has been made in the camphor monopoly. It is now proposed by the Chinese authorities that the camphor stills should be licensed before they are permitted to work. The cost of the license will be equivalent to a tax of about 22s. 6d. per cwt., a heavy tax, seeing that the actual value of the camphor at the place of production is very little over this amount.

PATENTS.

Manufacture of Artificial Tartaric Acids by Means of Cellulose, Saccharine, or Amylaceous Substances. A. U. Brehier and B. G. Talbot, Bordeaux, France. Eng. Pat. 3240, February 28, 1890. 6d.

THE process is based upon the production of oxygen by the decomposition of an alkaline permanganate in the presence of chlorine, and the action of the nascent oxygen upon the glucose bodies, converting them into tartaric acid. The glucose solution at 10° to 15° B. is contained in a closed cylindrical receptacle, and is subjected in the cold for four or five days to the action of alkaline permanganate and chlorine gas under slight pressure, and in absence of air. The solution is now exposed to the air in a chamber where the temperature is not below 20° C., and the process of oxidation and acidification is here completed. A clear limpid solution of tartaric acid is thus obtained, the particular form of tartaric acid varying according to the nature of the raw material used in its production.—A. J. K.

Improvements in the Production and Application of the Solution of Calcium Phosphate in Carbonic Acid Water for Use as a Beverage, or in Medicine or Pharmacy. T. H. Williams and W. H. Symons, London. Eng. Pat. 8454, May 31, 1890. 4d.

CALCIUM phosphate is dissolved in water by the aid of carbonic acid under a pressure of 100—120 lb., the excess of carbonic acid allowed to escape, and the settled liquor drawn off for use as a beverage or in medicine. The liquid may be charged with an excess of carbonic acid and bottled. —H. A.

A Process or Processes for the Manufacture of Artificial Musk. F. Valentiner, Plagwitz-Leipzig, Germany. Eng. Pat. 15,687, October 3, 1890. 4d.

A MIXTURE of equivalent proportions of isobutyl-, isopropyl-, or isoamyl-alcohol and xylene, turpentine or cymene is added gradually to concentrated sulphuric acid, care being taken that the temperature does not rise above 45° C. The product is added to fuming nitric acid and the dinitro-compound produced is precipitated with water, washed and purified by repeated crystallisation from alcohol. Thus obtained, the dinitro-compound can be used as a substitute for musk.

In order to obtain a perfume soluble in water and therefore suitable for perfuming soap, the product before nitration is heated at 150°—160° with strong and fuming sulphuric acid; the sulphonic acid produced is then nitrated and a soluble product obtained having an intense musk-like odour.—A. K. M.

Improvements in the Manufacture of Artificial Perfumes. G. Link, Wiesbaden, and R. Avenarius, Gaudesheim, Germany. Eng. Pat. 48, January 1, 1891. 4d.

TERTIARY amyl chloride, bromide, or iodide is boiled with three-quarters of its weight of chloride or bromide of iron until the evolution of acid has ceased. The product is then distilled with steam, dried and fractionated, and that portion passing over at 200°—208° which contains tertiary amyl-toluene, $C_{12}H_{18}$, is collected. One part of this is mixed with six parts of nitric acid of sp. gr. 1.5, 20 parts of fuming sulphuric acid, and heated on the water-bath for 20—30 hours. The melt is poured on to ice forming a viscid oil of a light brownish-yellow colour which solidifies, and after several crystallisations from alcohol yields light yellow prisms having a musk-like odour.—T. A. L.

Improvements in the Manufacture of Artificial Perfumes. G. Link, Wiesbaden, and R. Avenarius, Gaudesheim, Germany. Eng. Pat. 115, January 3, 1891. 4d.

THIS is a process for obtaining tertiary butyltolylmethane and its homologues and a hydrocarbon of the formula $C_{15}H_{24}$ and its homologues; further the conversion of these hydrocarbons into trinitro-derivatives which have an intense musk-like odour.

Iron chloride (0.75 part) or bromide is added by degrees to a mixture of isodibutylene hydrochloride (1 part) hydrobromide or hydroiodide with toluene (7 parts), and the whole is boiled with reflux condenser as long as acid is evolved. The product is subsequently fractionated, the portion distilling between 190° and 205° containing tertiary butyltolylmethane, whilst the fraction 230°—250° contains the hydrocarbon $C_{15}H_{24}$ —

When the homologues of toluene are employed in the place of the latter hydrocarbon, homologous products, e.g. $C_{13}H_{20}$, $C_{16}H_{26}$, &c., are obtained.

To obtain artificial musk the butyltolylmethane is treated with a mixture of 6 parts of nitric acid (sp. gr. 1.525) and 20 parts of fuming sulphuric acid.—A. K. M.

Washing Platinum Prints. A. Huszar. Der. Amat. Phot. 5, 74—75.

A ONE per cent. solution of crystallised copper sulphate may be used in place of hydrochloric acid for washing platinum prints.—C. H. B.

Some New Addition Compounds of Thiocarbamide, which afford evidence of its Constitution. J. Emerson Reynolds. Proc. Chem. Soc. 1891 [97], 78—79.

IN the course of the author's work on silicon compounds, a thiocarbamide derivative containing silicon tetrabromide was obtained which broke up on treatment with ethyl alcohol, affording among other products the fine crystalline substance $(H_4N_2CS)_4H_4NBr$. The same compound was subsequently obtained by direct union of its components, as was described in a former paper (Trans. Chem. Soc. 53, 857).

Thiocarbamide combines with ammonium bromide, iodide and chloride at the temperature of boiling alcohol, forming characteristic compounds of the type $(H_4N_2CS)_4H_4NBr$. But no compounds were formed under the conditions specified which contained fewer than four molecular proportions of amide to one of ammonium salt.

The author demonstrates on the basis of experimental results that the view that thiocarbamide is $CS(NH_2)_2$ is untenable, but these results are altogether in favour of the unsymmetrical structure $HN:C(SH)NH_2$.

It is pointed out that an interesting practical application of the compound $(H_4N_2CS)_4H_4NBr$ has recently been made by Colonel Waterhouse to the production of direct positive

photographs. So effective is the agent in securing the reversal of the photographic image, that the presence of only $\frac{1}{1000}$ th of a grain per ounce of "erikogen" developer causes the negative image that first appears to change into a rich-coloured positive.

In the discussion which followed, Mr. Groves, referring to the reversed photographs exhibited by Professor Reynolds, drew attention to the curious fact that the silver deposit which, in the early stage of development, apparently behaved like that forming an ordinary negative image, in the later stage became soluble.

The Decomposition of Silver Chloride by Light. Arthur Richardson. *Proc. Chem. Soc.* 1891 [97], 81-82.

The author describes experiments which have been made with a view to determine whether silver chloride which has been darkened by exposure to light under water contains oxygen. The nature of the change which occurs during decomposition of the chloride was also studied with reference to the part played by water.

Pure silver chloride was prepared by addition of dilute hydrochloric acid to a solution of pure silver nitrate, the precipitate being washed by decantation till free from acid. The following facts were observed during exposure:—

(1.) Oxygen was evolved, a part of which was present as ozone.

(2.) When small quantities of water were present, chlorine and hydrogen chloride were found in solution.

(3.) When a large volume of water was taken, hydrogen chloride, but no chlorine, was detected.

The influence of hydrogen chloride in retarding the decomposition of silver chloride is considered, and is explained from experimental results given, which show that even minute quantities of hydrogen chloride exercise a marked influence on the stability of chlorine water when exposed to light, the rate of decomposition of the silver chloride being dependent on the readiness with which the chlorine in solution and water interact to form hydrogen chloride.

In the examination of the darkened product for oxygen, a portion of the substance was taken which had lost 8 per cent of its total chlorine during exposure. After it had been dried at 110° C. till it ceased to lose weight, it was heated in a current of pure hydrogen, the gaseous products of the reduction being passed through a weighed phosphorus pentoxide tube. Before using this substance as an absorbent of moisture, it was ascertained that hydrogen chloride was not absorbed by it after contact for a few hours only.

The results show that the gain in weight of the drying tubes after the decomposition of the silver compound, which lasted from 7-8 hours, is so small as to preclude the possibility of the presence of an oxygen compound in the darkened product. The darkening of the carefully dried chloride was also observed to take place when exposed to light in a tube containing dry carbon tetrachloride from which all air had been removed by boiling. From these facts the author concludes that the darkened silver compound is of the nature of a subchloride rather than an oxychloride.

PATENTS.

An Improved Sensitised Flexible Film for Photographic Purposes. E. W. Foxlee, London. Eng. Pat. 3393, March 4, 1890. 6d.

A roll or web of heavily calendered or "surface" paper is coated with mola rubber or some other waterproof material, and then with gelatin containing sufficient alum to make it wholly or partially insoluble. When the gelatin is dry it is coated with collodion or other pyroxylin compound in a fluid or plastic condition, and when the latter is dry it is coated with sensitive gelatine bromide emulsion. After the emulsion has dried the back of the paper is moistened with the solvent originally employed with the

waterproofing material and the sensitised film is separated from the paper. The claim made is for the combination of these processes and not for any one of them separately.

—C. H. B.

Improvements in or relating to Flexible Phototype Plates. G. Balagny. Eng. Pat. 4178, March 17, 1890. 6d.

A FLEXIBLE support of collodion, gelatin, celhloid, paper, parchment, oilcloth, leather, &c. is coated with a film of gelatin or silver gelatino-bromide, or an emulsion prepared with any organic body forming a surface sensitive to light when sensitised with potassium dichromate. The films, after being dried, can be kept for a long time. When required for use they are sensitised by immersion for five minutes in a 3 per cent. solution of potassium dichromate, and are dried. They are then exposed in ordinary printing frames, and, since the film is flexible, it can be examined during the process of printing. When silver salts are present, the image is much darker than with dichromate or organic matter alone, and hence the proper depth of printing is more easily secured. The print is washed in water, supported on a lithographic stone or planed steel block, and inked up in the usual manner.—C. H. B.

Improvements in Photographic Printing Apparatus for Producing Photographic Copies at a Rapid Rate. W. F. Greene and F. H. Varley, London. Eng. Pat. 1956, March 29, 1890. 8d.

AN apparatus for obtaining, on a continuous sensitised band, rapid consecutive reproductions of photographic prints from photographic negatives of various subjects. Claims are made for the use, in combination, of a continuous roll of suitable paper, a series of sensitising, developing, toning, fixing, washing, and other tanks, with means for supplying the requisite solutions, and means for drawing off the waste liquids; means for squeezing the liquid from the band as it passes from each tank; means for exposing one face of the sensitised band, and means for simultaneously exposing both faces, the band being kept stationary during exposure, and released immediately afterwards; means for continually feeding the printing frame with the exact length of sensitised band required for each print.—C. H. B.

Improvements in Apparatus for Use in Developing Photographic Plates or Films. E. Fairweather, Forest Hill. Eng. Pat. 5742, April 16, 1890. 8d.

THE apparatus is designed for the development of photographic plates, &c. without the use of a dark room. It consists of a dish with a transparent non-actinic bottom and top, the top being removable in order to allow of the introduction of the plate. At the side, or in any other convenient position, are one or more funnels communicating with the inside of the dish; and there is also a waste-pipe, to allow of the dish being emptied. Development is watched through the top, or if a piece of mirror is placed under the dish, at an angle of 45°, development, &c. can also be watched through the bottom.—C. H. B.

Improvements in Photographic Baths for Developing and like Purposes. J. B. Brooks, Birmingham. Eng. Pat. 9413, June 18, 1890. 8d.

WITH a view to prevent the spilling of liquids, staining of hands, &c., the upper edges of the dishes (which may be made of ebonite, wood, metal, china, &c.) are provided with a hollow beading terminating in a flange or overhanging part directed inwards. The corners of the dish (or a special spout) have wings or flanges turned inwards. A movable spout or corner attachment, consisting of a cover plate with spring clips or other holders, may also be used.

—C. H. B.

Improvements relating to Films for Use in Photography. V. Planchon, Boulogne-sur-Mer, France. Eng. Pat. 14,189, September 9, 1890. 8d.

Rigid frames of suitable size and shape are fastened by simple pressure or by means of some adhesive substance to films, sensitive or insensitive, prior to the evaporation or oxidation of the solvents. When the film is completely dry the frame keeps it tight and smooth.—C. H. B.

An Improved Preparation of Chemicals adapted to the Development of Photographic Plates and the like. A. McDonald, Silloth. Eng. Pat. 15,091, September 24, 1890. 4d.

ONE part of sodium oxide, four parts of sodium carbonate, and eight parts of sodium sulphate, are fused together and made into sticks or pellets of convenient size or weight. Any proportions other than those given may be used if preferred. The sticks or pellets are dissolved in a measured quantity of water, together with a definite amount of solid pyrogallol.—C. H. B.

An Improved Process of Printing in Colours. W. Schumacher and L. C. Raegener, New York, U.S.A. Eng. Pat. 3342, February 24, 1891. 4d.

THIS invention relates to an improved process of printing in colours in such a way that the well-known character of a water-colour painting is closely imitated. The different colours of the picture are reproduced in wash tints by means of lithographic ink or crayon on the surface of as many separate transfer sheets as there are colours to be printed, these sheets being made of celluloid or other suitable hard unimpressible surface. The several tints are then transferred to separate stones or plates having grained surfaces. The printing surfaces are next coated with a layer of gum solution, dried, washed off, and rolled up in the usual way with transfer ink. They are then prepared with gum and acid, like a crayon drawing. Finally the different colours are printed from these prepared surfaces in register to correspond with the colours of the original picture.—W. E. K.

XXII.—EXPLOSIVES, MATCHES, Etc.

The Annual Report (Fifteenth) of Her Majesty's Inspectors of Explosives for 1890.

THE report of Her Majesty's Inspectors of Explosives just issued states that there has been no falling off in the high standard hitherto attained in the state of the factories and magazines visited under the Act. One new factory was licensed during the year, but no new explosives have been added to the list of authorised explosives. Five years ago there were 108 factories employing 7,484 persons, now there are 123 factories giving employment to 9,820 workers. During the year there were accidents during manufacture causing the death of eight persons. In regard to importation there has been an extraordinary decrease in the amount of foreign dynamite brought into this country compared with former years, only 371,650 lb. being imported last year as against an average of 1,000,000 lb. a year for the previous eight years. Part of this decrease is doubtless to be accounted for by an increase in the amount of the gelatinous forms of nitro-compounds imported, but still the total amount of nitroglycerin explosives imported was more than 400,000 lb. less than during the previous year. Dr. Dupré, in his report to the inspectors on the chemical work of the department, points out that although the gelatinised preparations are displacing the original Kieselguhr dynamite, they have dangers of their own which the manufacturer

has not yet completely overcome. The chief of these is their liability to exude a thin gelatin which is liquid at ordinary temperatures, and it seems also more difficult to insure absolute stability under the most trying conditions of temperature and storage. No authentic case of the spontaneous ignition of dynamite is on record, whereas there are several such in regard to gelatinous preparations. In the hottest climates these should be stored in water, when practicable, and carefully inspected periodically. Many of the imported samples of blasting gelatin failed to pass the prescribed tests, but the condition of the other explosives was, on the whole, very satisfactory. The French chalk to be used in the heat test will, in future, be defined as follows: "French chalk.—Commercial French chalk is carefully washed with distilled water, dried in a water oven, and then exposed under a bell jar to moist air until it has absorbed about 0.5 per cent. of moisture at the most. The chalk is then thoroughly mixed and bottled for use." The useful effect which the Explosives Act has exercised is seen from the facts that the average number of deaths during the last 10 years is eight per annum, whereas during the seven years preceding the Act the average number of deaths was 39.5 per annum; at that time there were only 55 factories, now there are 123.

Under the heading of Foreign Explosions the report notices that at Dupont's gunpowder factory, near Wilmington, U.S.A., about 80 tons of brown prismatic powder exploded. This is the largest amount of gunpowder accidentally exploded within the experience of the inspectors. An explosion which took place in a pieric acid factory at Mannheim possesses several interesting points. The accident is considered to have originated in the ignition (by friction or otherwise) of some pierate of lime which had been formed by the action of the pieric acid upon the whitewash and mortar of the walls. It was also found that 2,510 kilos. of pieric acid burnt away without explosion. The report also notices the more important explosions and fires which were due to petroleum.—W. M.

PATENTS.

A New Combustible Compound. W. Ruckteschell, St. Petersburg. Eng. Pat. 1349, December 16, 1885. Second Edition. 6d.

THIS is an invention for producing a special kind of nitrocellulose for actuating an explosion-engine patented by the same inventor. Wood fibre is first boiled with potash and then with dilute nitric acid. One part of the purified wood-fibre is then nitrated by treatment with one part of nitric and one part of sulphuric acid.—W. M.

Improvements in the Manufacture of Explosives. C. O. Lundholm and J. Sayers, Stevenston. Eng. Pat. 12,338, August 3, 1889. Second Edition. 4d.

THE inventors combine nitroglycerin and so-called insoluble nitrocellulose by means of heat and pressure. As this product is sometimes brittle, some soluble nitrocellulose or nitroxy-cellulose or nitrocellulose is added to the insoluble nitrocellulose. One per cent. of a camphor or mono- or dinitro-derivative of the aromatic group has a distinct effect in reducing brittleness and facilitating gelatinisation. The heat employed may be from 40° to 100° C., and the pressure at least one ton per square inch. (See also this Journal, 1889, 414, 764, and 893.)—W. M.

Improvements in the Manufacture of Gunpowder. H. Kolf, Bonn, Germany. Eng. Pat. 8811, June 7, 1890. 6d.

THIS invention consists in nitrating "carbon hydrates or plants or their waste products, which possess the qualities of carbon hydrates in a nitrogenous condition," under a pressure of from 2 to 5 atmospheres. After washing and drying, the mass is treated with sulphuretted hydrogen or a solution of potassium or sodium sulphides, &c., under a pressure of about 5 atmospheres; after again washing, the

material is treated under 4 or 5 atmospheres with a solution of an alkaline nitrate. The product is next treated with a solution of a "binitro-carbon hydrate" and moulded into suitable forms.—W. M.

Improvements in Blasting Cartridges. T. Puskas and I. Schlenker, Budapest, Austria-Hungary. Eng. Pat. 10,662, July 9, 1890. 6d.

The invention consists in making cartridge shells of every possible shape thicker along the surface or side further from the object to be blasted, whilst the opposite surface or side is made thin, so that the gases of the exploding blasting material have more difficulty in bursting the strong surface further from the object to be destroyed and less difficulty in bursting the thin surface nearer the said object, whereby the whole effect of the gases produced is directed towards the object to be burst, which is of great advantage.—W. M.

Improvements in the Manufacture of Matches. C. R. E. Bell, London. Eng. Pat. 330, January 7, 1891. 4d.

This invention consists in the use of coloured paraffin for coating matches, so that a glance is sufficient to show whether the matches have been properly paraffined or not.—W. M.

Improved Lucifer Matches. G. A. Rosen Rotter, Groningen, Holland. Eng. Pat. 3679, February 28, 1891.

This invention consists in using washed turf, peat, or moss, with or without addition of clay or resin, &c., pressed into suitable forms in place of the usual wood splints.—W. M.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

A Method of Determining the Consistency of Lubricating Grease. R. Kissling. Chem. Zeit. 1891, 15, 298—299.

See under XII., page 355

A Convenient Apparatus for the Determination of Melting Points. R. Ebert. Chem. Zeit. 15, 76.

The results obtained by different apparatus, several of which have been introduced lately (compare this Journal, 1890, 894) vary to a considerable extent, and the author recommends the following modification of the method with a sulphuric acid bath, which he has found accurate and convenient during a period of seven years. The apparatus consists of a test cylinder of about 25 mm. diameter, 15 mm. from the bottom of which a piece of perforated platinum foil is fitted, in order to prevent unequal heating. The cylinder is closed with lead foil or asbestos, in which the thermometer and the capillary tubes are fixed. The thermometer is about 15 mm. distant from the platinum foil, and the capillary tubes, which are longer than usual, are placed as near as possible to the bulb of the thermometer. Another capillary tube, bent at right angles at the lower end and passing through the lead foil or underneath the asbestos, reaches below the thermometer near the platinum foil, and serves to introduce a slow current of air. In working with this apparatus a small flame only is used, and the rising of the temperature is slow but equal. A further advantage is that no shaking of the liquid is necessary. The same sulphuric acid may be used many times, especially when the air passes through a calcium chloride tube before entering the apparatus. The cylinder employed should be of sufficient length, so that no inconvenience may be experienced from the escape of the sulphuric acid vapours.—H. S.

INORGANIC CHEMISTRY.— QUANTITATIVE.

Determination of Carbon in Steel. A. A. Blair. J. Anal. and Appl. Chem. March, 1891.

THE author has repeated Dudley's experiments in connexion with the use of ammonium copper chloride as a solvent when estimating carbon in steel and confirms Dudley's results (this Journal, 1891, 67—68) to the effect that the double chloride contains carbonaceous matter, and that when used the quantity of carbon found diminishes with each crystallisation of the double salt, and is also lower when neutral than when acid solutions of the double salt are used. This latter occurrence is, in Langley's opinion, due to the precipitation of carbon from the acid solution of the double salt, whereas the author thinks that the neutral solution becomes slightly alkaline and dissolves some of the carbonaceous residue; he also attributes the carbon present in this salt to hydrocarbonaceous matter derived from the gas-liquor from which the ammonium salt is prepared; he finds, however, that this source of trouble may be entirely avoided by the use of potassium copper chloride which in experiments proved not only quite efficient, but also a safer and more desirable solvent than the ammonium copper salt.

For the combustion of the carbonaceous residue from the steel, the author employs a platinum tube 26 in. long and $\frac{3}{16}$ ths of an inch diameter, the front part in the furnace is filled for 6 in. with granulated copper oxide kept in position by platinum gauze plugs, a similar plug being used behind the platinum boat; the latter is 6 in. long and just large enough to go in the tube; and for the direct combustion of steel in oxygen it is provided with a platinum foil cover having half circles cut through at intervals of half an inch, and in use the semi-circular flaps thus formed are set up at an angle of 45° so as to direct the current of gas down into the boat. The oxygen and air are admitted under pressure, passing through potash and over fragments of pumice before entering the tube. The issuing gas is in the author's opinion most conveniently and safely purified by the following arrangement:—Two of the U-tubes ordinarily employed for such purposes are used; the larger bulb of the first tube is filled with fragments the size of split peas of dry cuprous chloride for absorbing hydrochloric acid and chlorine, the remaining part of the tube being charged with granular anhydrous copper sulphate and a plug of asbestos; in the small bulb of the next tube a plug of cotton is placed and moistened with one, or at the outside two, drops of water, to adjust equilibrium of moisture, the other portion of this tube being filled with dried, not fused, calcium chloride; the author fears the presence of lime in the fused salt. The experiments also indicate the great value of using a standard iron of known carbon content for such investigations as these.—D. A. L.

Errors in the Volumetric Determination of Zinc by Potassium Ferrocyanide and how to avoid them. D. F. Moldenhauer. Chem. Zeit. 15, 223—224.

THE extreme sensitiveness of copper sulphate paper as an indicator (this Journal, 1890, 108—109) has enabled the author to make observations on the above subject. The potassium ferrocyanide solution which has to be used for the titration of zinc, is first colourless, but soon some ferric oxide is precipitated and the liquid assumes a yellow colour. This may be prevented by adding 1—2 grms. of caustic alkali to 1,000 cc. of the solution, and keeping the latter in opaque bottles and dark places. The correctness of the volumetric determination is not affected by calcium, strontium, aluminium, lead, and ferric oxide; much ferric oxide, however, may produce a slight difference. But in the presence of magnesium 3—6 per cent. more than the correct quantity of potassium ferrocyanide may be necessary for the titration. Manganese oxide produces a similar difference which however seldom exceeds 4 per cent.

To avoid these errors the author recommends the following method:—

2.50 grms. of zinc ore are dissolved in hydrochloric acid, some nitric acid added, and the liquid diluted without

filtration to 250 cc. A Geissler's burette is rinsed and filled with this liquid, 50 cc. of which are mixed in a flask with 10 cc. of ammonia and 5 cc. of a solution, 100 cc. of which contain 5 grms. of ammonium carbonate, 5 grms. of ammonium chloride and 10 cc. of ammonia. The mixture is heated until a precipitate is formed and is then allowed to stand until cool. Meanwhile 25 cc. are poured off from the burette, and mixed with 10 cc. of ammonia and titrated approximately; another 25 cc. of the original liquid are added, and then an accurate titration is made. To the liquid in the first flask, when cool, between 1 and 2 cc. (not more) of sodium phosphate solution of 10 per cent. strength is added, and the mixture shaken, manganese oxide and magnesia, if present, being thereby precipitated; then another titration is made, the final reaction of which has to be controlled after a short time. The difference between this and the first titration gives the amount of magnesia or manganese oxide present. The advantages of this method are, that no filtrations are necessary, that the titrations can also be made by artificial light, and that the final reaction is very delicate.—H. S.

Arsenic in Crude Acids. Chem. Zeit. 15, 43.

In reply to a complaint that crude acids often contain large quantities of arsenic, the following figures are given which show that, as a rule, this is by no means the case:—

Arsenic in 120 Kilos. of Sulphuric Acid.		Arsenic in 100 Kilos. of Hydrochloric Acid.	
Grms. 1·3		Grms. 2·4	
4·4		3·1	
2·3		10·4

ORGANIC CHEMISTRY.—QUALITATIVE.

A Test for Strophanthin. Holbing. Schweiz. Wochenschr. f. Pharm. 25, 239.

If a trace of strophanthin, dissolved in a drop of water, be mixed with ferric chloride and a drop of sulphuric acid added, a reddish-brown precipitate forms, which either at once or after standing some hours turns to an emerald green colour.—H. S. P.

Gayon's Test for Aldehyde. H. Bornträger. Zeits. Anal. Chem. 30, 208.

As a test for aldehyde in spirit, Gayon (Compt. Rend. 105, 1182; this Journal, 1888, 238) recommends the use of a solution of magenta, which has been decolourised by means of a little hydrochloric acid and a large quantity of acid sodium sulphite. The author finds this method unreliable, partly because the action of the air induces the oxidation of the acid sodium sulphite to acid sodium sulphate and causes the reappearance of the magenta colour. On the other hand the presence of acetal which occurs in nearly every spirit that has not been very well rectified, and especially in Russian spirit, destroys the colour of the magenta, so that when a little aldehyde is present together with much acetal, no colour reaction takes place.—H. S. P.

Ihl's Tests for Lignin: A Question of Priority. M. Niggel. Chem. Zeit. 15, 298.

THE author considers that Ihl ignores the existence of the greater portion of literature concerning the chemical reactions of lignin, since that chemist continues to describe as new reactions which are already well known. Thus, Ihl in a recent article (Chem. Zeit. 15, 201; see page 563), refers to a paper published by himself in 1885, in which the property possessed by phenols of yielding colour-reactions with lignin is pointed out. This property was discovered several years before that date by v. Höhnelt (Sitzungsbericht. d. Akad. d. Wissensch. Wien, 76.), who observed the reaction with phenol, and subsequently by Wiesner, who showed that such colour-reactions were produced with catechol, resorcinol, pyrogallol, and phloroglucinol. The author, again, in 1881 drew attention to these reactions in an article discussing the chemical nature of lignin.

The pyrrol reaction (see this Journal, 1887, 306; 1888, 51; 1889, 121, 640, 914, 1012; 1890, 418, 555, 770; 1891, 165), also, to which Ihl gives preference as being the most delicate test for lignin, was known and described before it was discovered by Ihl. It is mentioned, for instance, by Behrens in his work (Hilfsbuch zur Anleitung Microscopischer Arbeiten, 1883), a book in which descriptions are given of most of the "new" reactions discovered by Ihl. The author has long since replaced pyrrol in his investigations by indole, which is a more stable and delicate reagent; Singer, Behrens, Tschireh, and Zipperer have all testified to the superiority of indole.

Further, to avoid mistaking membranes which are merely lignified for true lignin, the necessity for concurrent microscopical investigation, whilst making the chemical tests, is pointed out. Ihl appears to have overlooked this.

On the Determination of Pine-Rosin in Bees-wax.

H. Röttger. Chem. Zeit. 15, 45.

To effect such determination various methods are known, the degree of accuracy of which is different.

1. *Donath's Method.*—Some of the wax is boiled in a test tube for 15 minutes with concentrated nitric acid, and then cold water added in a fine jet, by which the wax is solidified. The liquid is now poured off and, when cold or if water is added to it will, if pine-rosin is present, yield a yellowish flocculent precipitate which dissolves in ammonia, giving a red-brown colouration. The author finds that this method gives accurate results, but that the following is more convenient.

2. *E. Schmidt's Method.*—Five grms. of wax are boiled with four or five times as much crude nitric acid (1·32–1·33 sp. gr.). After one minute the mixture is diluted with cold water to twice its volume, and then ammonia must be added until a strong odour of ammonia is given off, the liquid during the operation being frequently shaken. The liquid, which has to be poured off from the solidified wax, is yellow, if the wax was pure, but if it was adulterated by pine-rosin, it shows a more or less red-brown colouration (in consequence of the nitrogenous products which have been formed). This method is a very good one, and the author confirms the statement, that as little as 1 per cent. of pine-rosin can be determined with perfect accuracy. It can be made still more accurate if the alcoholic extract described in the subsequent test be used.

3. *Hager's Method* is modified by the author as follows:—A sample of the wax to be tested is boiled with 15 times its volume of dilute alcohol (of 50 per cent. strength volumetrically), and when perfectly cold filtered, if necessary. Then the liquid is diluted with water to double its volume. If the wax is pure, this diluted liquid is clear, but if pine-resin be present it is of a milky appearance, and not clear. As little as 2 per cent. of pine-resin can with accuracy be detected by this method.

4. *Sedna's test*, which consists in dissolving the wax in chloroform and adding lime water, is, according to the author, of no value whatever, as he never succeeded in obtaining the grey-brown flocculent substance which Sedna describes as indicating the presence of pine-resin. (See also this Journal, 1890, 83 and 771; and 1891, 165.)

—H. S.

On the Composition of Woody Matter and the Influence of Alkalies and Calcium Bisulphite on Wood. A. Thl. Chem. Zeit. 15, 201—202.

See under XIX., page 563.

On the Quantitative Determination of Mechanical Wood Pulp in Paper. R. Benedikt and M. Bamberger. Chem. Zeit. 15, 221—222.

Two methods have hitherto been usually employed for this purpose, viz.:

1. Godeffroy's method (compare Mittheil. d. k. k. Techn. Gew. Museums, 1888, 18, 66—77, and 1889, 9—11; this Journal, 1888, 863—864; 1889, 574—576). The paper to

be tested has to be extracted in consecutive order by the following liquids: cold and boiling water, hot solution of

THE DETERMINATION OF METHOXAL IN LIGNIN.

tartaric acid in alcohol of 80 per cent. strength, hot water and cold water, and, finally, alcohol and ether. After that the residue is boiled with a dilute solution of gold chloride, and the gold which is hereby obtained, weighed, as

Size.	Water.	Ash.	Methyl Number.	Mechanical Wood-Pulp found.	Actual Composition of Paper.

Vegetable size	7.76	1.90	11.95	54.05	50	50 per cent. of cellulose.

mechanical wood-pulp has the property of reducing 11.285 per cent. of gold on the average. Ehimann has proved that this method gives fairly good results, but the great number of extracts which have to be made, if a reliable result is expected, render this method very inconvenient.

2. *Techl's method* (see Jahresber. d. Wiener Handelsak. 1890, 159). This test is based upon the observation that mechanical wood-pulp, if digested with a mixture of 60 per cent. of sulphuric acid and 40 per cent. of water, is said always to yield a residue of 24.5 per cent. But this observation cannot be considered conclusive, as it is based only upon two determinations.

Now the authors have recently shown that lignin has a rather high "methyl number" (compare this Journal, 1889, 735 and 925; 1890, 659 and 1156—1157), and they have already pointed out that it will be possible to calculate the

quantity of mechanical wood-pulp in paper by finding the methyl numbers of lignin contained in it. Although the methyl numbers of different kinds of wood have been found to vary, those woods which are mostly used in the manufacture of mechanical wood-pulp do not differ much in this respect, and, besides, the different kinds of wood may be ascertained by a preceding microscopical examination of the paper and the corresponding methyl numbers chosen. The following table contains some of the woods which are of practical value:—

	Methyl Number of Woods dried at 100 °C.
Pine.....	22.6
Red fir.....	22.5
White fir.....	21.5
Ash.....	22.6

The determinations have been made with the apparatus of Benedikt and Grüssner (see this Journal, 1889, 735—736; 1891, 163) which is modified, however, in the following way (see Fig.):—The two glass tubes *a* and *b* reaching to the bottom of *A* are connected by india-rubber tubes of large diameter with a copper vessel *B* of the shape indicated in the Figure. *A* and *B* are filled with water, and *B* is heated by a Bunsen burner. As soon as the water in *B* boils, the opening at the end of the tube *a* is closed with the finger for a short time, and the consequence is that *b* fills with water, and as soon as *a* is opened again a regular circulation takes place from *A* through *b* to *B* and from there through *a*, back to *A*. Instead of the copper vessel described, a glass flask may be used, arranged like an ordinary washing bottle, the longer glass tube being bent downwards.

The determination of the methyl number should be made as carefully as possible, as a difference of one in this number represents 5 per cent. of mechanical wood-pulp. The test is finished only when the silver nitrate solution remains perfectly clear above the precipitate (compare this Journal, 1889, 736). For each test 1.5 to 2.0 grms. of the substance and 30 cc. of hydriodic acid of 1.70 sp. gr. are used. Small quantities of sulphur, as may be contained in the animal or vegetable sizes of the paper, do not interfere with the test, but a larger amount of sulphur makes the methyl number smaller by forming mercaptan. This method therefore cannot be used for papers containing gypsum or barium sulphate. The table on previous page shows the results obtained by this method, as compared with the actual composition of different kinds of paper.

The method may further be used for finding the amount of lignin in cellulose.—H. S.

Estimation of Fatty Bodies in Vegetable Organisms. W. Maxwell. Amer. Chem. J. 1891, 13—16.

The author chiefly experimented with cotton seed, which had been reduced to the greatest state of fineness, and extracted in the Knorr apparatus. It was found that in order to ensure complete extraction the ether ought to act for at least 15 hours. The same sample when treated for 8½ hours yielded 37.39 per cent. of extract, calculating on the dry substance, but a 15 hours' extraction gave 38.38 per cent.

The substituted glycerides, or lecithins, have lately become of some analytical importance, as their presence enables an analyst to testify as to the presence, and even to approximately estimate the quantity, of several fatty matters, such as the oily substance of the seeds of the vetch, and horse-bean, or even of yolk of egg. The ethereal extract has only to be burned with mixed alkali salts (nitrate and carbonate?) and the ash examined for phosphoric acid. From its amount the percentage of lecithin may be calculated by multiplying by the factor 10.87.

The author has, however, found that only about one-half of the lecithin is readily extracted by the direct treatment with the ether. The residue must again be extracted with boiling alcohol, and the extract once more immediately exhausted with ether, when it will give up the remainder of the lecithin.—L. DE K.

On the Behaviour of the Fatty Bodies and the Role of the Lecithins during Normal Germination. W. Maxwell. Amer. Chem. J. 1891, 16—24.

The author, after pointing out the difficulties in the way of estimating the normal glycerides in vegetable organisms, owing to the presence and solubility of cholesterin, &c., remarks that the lecithins may be estimated in germinated materials from the organic phosphorus, separated with ether and alcohol. This is supported by proof that the phosphorus is present as a lecithin since cholin is yielded as a decomposition product. The seeds experimented upon were those of *Phaseolus vulgaris*, *Gossypium*, and *Lea Mays*; and germination was stopped at certain stages of development, not at certain periods, as is usual.

In the first named the increase of lecithin was 15.9 per cent. at the end of the first stage. In *Gossypium* the amount rose and fell again, showing that some was again decomposed, as the plant further developed. From these results the author concludes that new lecithins were formed from the inorganic phosphorus compounds, but it is not clear that the whole of the amount discovered was reorganised. In fact the question as to what happens to the original lecithin in the mature seed must be solved hereafter.

—L. DE K.

The Quantitative Estimation of Penta-glucoses in Plants. G. de Chalmot and B. Tollens. Ber. 24, 691—695.

The authors have modified Günther and Tollens' method (this Journal, 1890, 903) of estimating penta-glucoses, in so far that they precipitate the furfural produced by the distillation of certain carbohydrates with hydrochloric acid, as furfural hydrazone. Precipitation is effected in presence of acetic acid by means of a solution of phenylhydrazine acetate. The precipitate is collected in an asbestos filtering tube and dried by suction at 50—60° C. A correction is applied to the weight of furfural found to allow for the slight solubility of the precipitate in the liquid. The average yield of furfural obtained by the distillation of various sugars with hydrochloric acid is as follows:—

	Per Cent.
Arabinose.....	48.72 of furfural.
Xylose.....	56.25 of furfural.
Penta-glucoses.....	52.5 of furfural.

A number of carbohydrate substances were analysed by the above process, the furfural found being calculated into the corresponding amount of arabinose or xylose. The results obtained are given below:—

	Per Cent.
Cherry gum (new, of good quality).....	45—46 of arabinose.
Wheaten straw.....	24.9 of xylose.
Oat straw.....	22.6 of xylose.
Beech wood.....	19.7 of xylose.
Pine wood.....	7.8 of xylose.

(See also this Journal, 1891, 473.)—H. T. P.

Determination of Turpentine in Paints and Varnishes. H. J. Phillips. Chem. News 1891, 63, 275.

When paints or varnishes are distilled in air, it is known that oxidation-products are formed giving a low result for turpentine, while the residue of linseed oil, &c. is rendered useless for further examination owing to the formation of the inert linoxyn, &c. In ordinary cases the distillation may be conveniently carried on in a gentle current of coal-gas.

The figure represents the apparatus used by the writer. *B* is a three-way tube fitted into the tubulure of the retort *A*, through a cork, the end of the tube being about half an inch

from the surface of the sample; into the part *B* a thermometer, *E*, is fitted, supported by a rubber plug at *C*. *D* is connected with a supply of coal-gas. *F* is a tared receiver,

which is to be kept in a basin containing cold water. G is a small tube for allowing the gas to escape. About 150 grms. of the sample are weighed into the retort, and connected to the tared receiver as in sketch. The retort is now suspended in a glass air-bath (a beaker with its bottom cut out is convenient) over wire-gauze on a tripod stand. Before proceeding with the distillation a gentle current of coal-gas is made to pass through the apparatus, and when all the air has been driven out the issuing gas is lighted at G, and the gas turned down until the flame is about the size of a pea. A rush of gas must be avoided, or there would be a loss of turps. A small flame is now placed under the retort, and the distillation proceeded with gently. The turpentine should drop into the receiver without affecting the gas issuing at G. The temperature necessary for the complete expulsion of turps may be about 220° C. When all the turpentine has come over, detach F and plug the end of the retort with a cork, leaving the gas still turned on until it be required to examine the residuum, which is thus kept free from oxidation.

The Volumetric Determination of Hydrocarbon Vapours.

W. Hempel and L. M. Dennis. Ber. **24**, 1162—1164.

THE authors have compared Bunsen's and E. St. Claire Deville's (this Journal, 1889, 972—973) methods for the determination of the hydrocarbon vapours (benzene and naphthalene) in coal-gas with the result that they find the former gives considerably higher results than the latter. Bunsen's method consists in passing a large volume of the gas through a long wide tube and a wash-bottle filled with alcohol, the hydrocarbons being then separated from the alcohol by which they have been dissolved by the addition of a saturated aqueous solution of sodium chloride. In Deville's method the gas is cooled to -22°C , whereby the suspended vapours are deposited. 15.4 cc. of liquid hydrocarbons containing 3.5 cc. of benzene and 13 cc. of liquid hydrocarbons containing 5 cc. of benzene were obtained respectively by the above two methods from 1,497 cc. of Dresden gas. The low result in the latter case is traced to the difficulty of keeping a constant temperature of -22°C . for several days as is required for the experiment. With the view of making the method both handier and more accurate, the following plan has been devised. The coal-gas is measured in an ordinary Hempel burette over water saturated with the gas, which is then connected with a gas pipette, having the form of the Hempel explosion pipette, by means of a capillary tube, in the usual manner. The pipette contains 1 cc. of absolute alcohol enclosed by means of mercury; this quantity of alcohol can be readily introduced by siphoning it in from a gas burette. The alcohol should first be saturated with coal-gas so as to prevent its absorbing any constituents other than the hydrocarbon vapours. The coal-gas having been siphoned into the pipette it is agitated with the alcohol for 3 minutes, then siphoned back and passed into a similar pipette containing 1 cc. of water instead of alcohol, which effects the absorption of the alcohol vapours. The water in this second pipette must also be saturated with the coal-gas before use. In passing the gas into the alcohol-pipette care must be taken not to allow any of the water in the burette to pass beyond the capillary tube connecting the burette with the pipette.

The whole process can be carried out in 20 minutes, and only 100 cc. of coal-gas are required for the experiment. A further advantage is found in the fact that the results may be expressed directly as percentage by volume, which is not the case with the methods referred to above.

Dresden gas analysed in this way gave in two experiments 0.74 and 0.70 per cent. of hydrocarbon vapours, employing burettes filled with mercury; using water in the burettes the results varied from 0.50—0.63 per cent. An artificial sample of gas prepared by passing coal-gas through benzene gave the following results:—

1. 90 cc. of gas passed through benzene increased in volume to 93.1 cc. After absorption as above, 89.4 cc. were left.

2. 90 cc. of gas after passing through benzene increased to 93.0 cc. After absorption 89.4 cc. were left.

In these cases only 1 cc. of alcohol was employed, which is therefore sufficient to absorb 3 cc. of hydrocarbon vapours.

Since these vapours are dissolved to a considerable extent by caustic soda it is desirable to determine them before proceeding to the determination of the carbon dioxide in the gas.—C. A. K.

Purity of Benzene. C. Liebermann and A. Seyewetz.

Ber. **24**, 788—790.

THE authors find that so-called pure benzene of commerce frequently gives a comparatively abundant white crystalline precipitate with phenylhydrazine. This they traced to carbon bisulphide, the amount of which they estimate at 0.2 to 0.3 per cent., giving a precipitate equal to 0.8 per cent. of the benzene. Phenylhydrazine is accordingly recommended as a test for carbon bisulphide; three or four drops are added to about 10 cc. benzene; the mixture is frequently shaken and allowed to stand for 1 to 1½ hours. In this way it is possible to detect carbon bisulphide when present to the extent of only 0.03 per cent.

Benzene purified by crystallisation rarely contains carbon bisulphide.—A. K. M.

ANALYTICAL AND SCIENTIFIC NOTES.

Oxy-pyruvic Acid, a New Product of the Decomposition of Cellulose. W. Will. Ber. **24**, 400—407.

WHEN collodion is treated with 10 per cent. soda in the cold and the alkaline solution after standing two hours is neutralised by acetic or sulphuric acid, a slimy precipitate falls out with the simultaneous evolution of carbon dioxide and oxide of nitrogen. The precipitate is insoluble in water but easily soluble in alcohol and alkalis; it contains nitrogen, and has been called cellulose dinitrate, as it does not yield cellulose when treated with ferrous chloride. This name is hardly correct; it appears rather to be the oxime of a ketone.

If the alkaline solution of collodion be allowed to stand for 20—30 hours, acids no longer precipitate the solution. The solution reduces alkaline copper solution and ammoniacal silver nitrate, and contains a body which yields a yellow hydrazine. This body is oxy-pyruvic acid, the osazone has a composition corresponding to the formula $\text{COOH.C}(\text{N}_2\text{H}_4.\text{C}_6\text{H}_5)_2.\text{CH}(\text{N}_2\text{H}_4.\text{C}_6\text{H}_5)$. The free acid may be obtained direct from the alkaline solution of collodion. Analyses of its salts and the determination of its molecular weight by Raoult's method leave no doubt as to the correctness of the above formula. Its constitution might be aldehydic or ketonic, but the action of oxidising agents on it show that it is expressed by $\text{COOH.CO.CH}_2\text{OH}$.

—A. L. S.

PATENT.

Improvement in the Means of Determining Acidity or Alkalinity in Milk or other Substances. A. W. Stokes, London. Eng. Pat. 8551, June 3, 1890. 4d.

PELLETS are made containing a definite quantity of some acid or alkali together with a suitable indicator, and these are added one by one to a measured quantity of the liquid to be tested, until the indicator shows that the acid or alkali has been completely neutralised. The quantity of free acid or alkali present is ascertained from the number of pellets required.

In the case of milk 10 cc. of the liquid is taken and the pellets contain 0.212 gm. of anhydrous sodium carbonate moistened with an alcoholic solution of phenolphthalein. The number of pellets required to produce a permanent pink colouration gives at once the quantity of lactic acid in tenths of a per cent.—C. H. B.

New Books.

CHEMISCH-TECHNISCHES REPERTORIUM. Uebersichtlich geordnete Mittheilungen der neuesten Erfindungen, Fortschritte und Verbesserungen auf dem Gebiete der Technischen und Industriellen Chemie. Mit Hinweis auf Maschinen, Apparate und Literatur. Herausgegeben von Dr. EMIL JACOBSEN. 1890. Erstes Halbjahr. Erste Hälfte. Berlin: R. Gaertner's Verlagsbuchhandlung, Hermann Heyfelder. Schönebergerstrasse 26, S.W. London: H. Grevel and Co., 33, King Street, Covent Garden.

The first issue for the first half year of 1890. It contains 144 pages of subject-matter, copiously illustrated with wood engravings. In the text the following subjects are treated of:—Building Materials, Cements and Artificial Stone, Colouring Matters, Dyeing and Calico Printing, Fats, Oils, Illuminating and Heating Materials, Fermented Liquors, Tanning, Leather and Glue Manufacture, Textiles, Glass and Earthenware, Wood and Horn, India-rubber, Cements, Plasters and Artificial Stone, Lakes, Varnishes and Paints. Metals.

THE POCKET-BOOK OF MENSURATION AND GAUGING, &c., FOR REVENUE OFFICERS, BREWERS, SPIRIT MERCHANTS, &c. By J. B. MANT. Second Edition, Revised, 1891. London: Crosby Lockwood & Son, 7, Stationers' Hall Court, Ludgate Hill.

Small oblong pocket-book size, with india-rubber band. Commences with 16 lined blank pages. Then follows title-page; Dedication to W. H. Johnston, Esq., Collector of Inland Revenue, &c.; Preface to first and second editions, and 249 pages of Formulae, Numerical and other data and Tabulated figures, data, &c. The Alphabetical Index is at the beginning and takes the place generally occupied by the Table of Contents.

WATER ANALYSIS, A PRACTICAL TREATISE ON THE EXAMINATION OF POTABLE WATER. By J. ALFRED WANKLYN and ERNEST THEOPHILUS CHAPMAN. Eighth Edition. By J. ALFRED WANKLYN, M.R.C.S. London: Kegan Paul, Trench, Trübner & Co., Ltd., 1891.

CROWN octavo volume, bound in black cloth, containing with slight modification and addition the same matter as the last, the seventh edition. The addition is contained in an explicit statement of directions for preparing the solutions necessary for the Moist Combustion process, and will be found on page 54. These directions it will be remembered formed the subject of a patent by the author, taken out years ago. That patent has now run out, as the directions it contained now appear in the book, *loc. cit.* (see this Journal, 1889, 140).

Trade Report.

(From Board of Trade and other Journals.)

TARIFF CHANGES AND CUSTOMS REGULATIONS.

RUSSIA.

Customs Decision.

The *Bulletin du Musée Commercial* says that by a circular dated the 10th April last the Russian Customs Department announces that all explosive materials sent from abroad in packets without mention of the fact being made in the declarations relative to these packets, will be confiscated on entry into Russia, as articles introduced clandestinely.

UNITED STATES.

Customs Decisions.

The following decisions respecting the construction to be given to Acts of Congress relating to the classification of articles in the Customs tariff and the application of the Customs laws of the United States, have recently been given by the Customs authorities in that country:—

White lead, ochre, and umber, all in oil, and put up in small metal tubes such as are used by artists, are dutiable at 25 per cent., under the provision of paragraph 61, for "artists' colours, in tubes or otherwise."

Wool grease or dregas is dutiable at one-half of one cent. per pound under paragraph 599.

Chemical wood pulp, bleached, is dutiable at 6 dollars per ton.

Articles known as plateaus, used as ornamental dishes for the centre of tables, and for holding fruit, and for flower stands, and also for salvers, consisting of "discs of plate glass, silvered, from 6 to 16 in. in diameter, and set into a metal case with feet," are classified under paragraph 143 of the Tariff Act of 3rd March 1882, which provides a rate of 45 per cent. duty *ad valorem* on "porcelain and Bohemian glass, chemical glassware, painted glassware, stained glass, and all other manufactures of glass, or of which glass shall be the component material of chief value, not specially enumerated or provided for in this Act."

Copper, in pyrites ore, is admitted free of duty.

Candle tar, a by-product obtained in the manufacture of candles from animal grease, commercially known as "candle tar," and having a distinctive use as a waterproof lining for barrels and a waterproof covering for roofs, is dutiable as a non-enumerated manufactured article at 20 per cent.

Dead oil, a distillate of coal tar, is dutiable at the rate of 25 per cent. *ad valorem* as a distilled oil, under paragraph 76, N.T.

Straw intended for the manufacture of paper is dutiable at 30 per cent., under paragraph 289, N.T.

Regulus of antimony is dutiable, under paragraph 187 of the new Tariff Act of 1st October 1890, at three-fourths of 1 per cent. per pound.

CHILE.

Customs Legislation.

Mr. Lewis Joel, Her Majesty's Consul-General at Valparaíso, in a report to the Foreign Office, dated the 11th April, transmits copy and translation of a decree of the Chilean Government which came into force on the 15th April, making obligatory the despatch and payment of duties at the Custom houses of the Republic of the articles therein enumerated. The translation is as follows:—

It is declared obligatory the despatch of the following articles:—

1st. Acids, oils, effervescing and mineral waters, asbestos, in whatever form, sugar, sulphur, washing blue, weighing scales, varnish, empty bottles, pasteboard, cement, beer,

raw sugar, chloride of lime, concrete sugar, soda crystals or soda ash, floor cloth, phosphorus, Bengal lights, tallow and grease, black lead, common soap, sweetened juices, looking-glasses (silvered or not), hard, wrapping-paper, kite-paper, petroleum, turpentine, common salt, caustic soda, sulphate of copper, colouring earths, chalk, candles, common glass, and packages having straw in sight. Large packages which cannot conveniently be stored, packages exceeding 100 kilos, weight and goods in bulk, considering as such those without exterior packing. Goods free of duty, all those which are not sufficiently packed to prevent loss of contents or those that are inadequate for storing in the ordinary manner.

2nd. These goods may be reshipped for foreign countries always provided that the interested party prove its identity to the satisfaction of the respective Custom houses, in which case the duties will be refunded.

THE NEW FRENCH TARIFF ON SOAPS.

Common and toilet soaps are among the articles upon which the Customs Commission of the French Chamber of Deputies proposes to increase the duties very considerably. At present common soaps pay 6 frs. per 100 kilos. It is proposed to increase this tax to 13 frs. for the minimum, and 17 frs. for the general tariff. The minimum tariff on perfumery soaps is to be raised from 8 frs. to 20 frs., and the general tariff from 12 frs. to 26 frs. The Commission justify their recommendations upon the ground that the internal taxes upon many of the ingredients used in soap-making have increased considerably since the fixing of the last tariff. Transparent soaps are to be placed in a separate category and taxed at 60 frs. to 70 frs. per 100 kilos, because, the Commission argues, it is impossible to ascertain by chemical means whether alcohol has or has not been used in their manufacture, while foreign manufacturers, usually by simply declaring that no alcohol has been used, contrive to pass them at the ordinary duty upon common soaps. On the other hand, if alcohol has been used, then the foreign alcoholic transparent soap has an enormous advantage over the home-made, as the French manufacturer pays an excise of 1.56 frs. per litre on alcohols, equal to from 17 frs. to 156 frs. per 100 kilos, of soap, upon which no drawback is allowed.

THE FRENCH TARIFF ON CHEMICALS.

The Paris Chamber of Commerce has submitted to the French Legislature its report on the modifications which it considers desirable in the new Customs tariff. So far as chemicals are concerned, the Chamber is generally in favour of a reduction of the present duties. It is pointed out that whereas 15 years ago France imported 12,000 tons of soda a year, now her industry has grown so large that she actually exports over 20,000 tons annually. The Chamber, therefore, suggests that the following duties will be sufficiently high: caustic soda, 1 frs. per 100 kilos, or 10 per cent. *ad val.*; carbonate of soda, 2 frs. per 100 kilos, or 10 per cent. *ad val.*; chloride of lime, 30 frs., or 12 per cent. *ad val.* With respect to fine chemicals the Chamber supports the continuation of the present tariff for all but the following: Bromine to be placed on the free list (present duty 1 fr. per kilo); all bromides to be taxed 5 per cent. *ad val.*, or 25 frs. per 100 kilos. The tax on iodine, now 4 frs. per kilo, or about 20 per cent. *ad val.*, to be maintained in the interests of the kelp industry, but that on iodides (now about 5 per cent. *ad val.*) to be raised to 4 frs. per kilo, or about 20 per cent., thus placing the manufactured product on a level with the raw. The late commercial war with Italy led to the placing of a heavy duty on concentrated lemon and bergamot juices, which the report wishes to abolish entirely. It would also free citrate of lime, and reduce the duty on crystallised citric acid from 50 frs. to 25 frs., or about 5 per cent. The report further asks that citrates may be made dutiable at 50 frs. per 100 kilos, instead of *ad valorem*, as at present. The oxalic acid manufacture is so strong and well organised in France that it is considered safe to place it on the free list, or at any rate to reduce the duty to 5 per cent. — *Chemical Trade Journal*

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

FRANCE.

The Merchandise Marks Act.

There is no change to report in connection with British trade at Havre, nor, with the prospect of a higher tariff on all manufactured articles, is there any chance of England doing a larger business after 1891. The Merchandise Marks Act continues to be applied with severity by the English Customs to goods sent to England in transit for foreign countries, especially with those going to the United States, and Britain is accused of wanting to monopolise the English language. Among other cases brought forward is one of 67 casks of earthenware tiles, manufactured at Creil, for a firm at New York, and bearing the words, burnt in, "Universal Wall Tiles Company." They were sent to Southampton for transhipment by one of the National Line steamers, and were stopped by the Customs, who imposed a fine of 10*l.*, and required the removal of the words—which was impossible—before releasing the goods. Finally, the casks were allowed to be forwarded and the fine was remitted, but permission for future transshipments of the same kind was refused. The result is that the goods, instead of being sent in British, are carried in French and German, vessels.

ITALY.

Trade with the United Kingdom.

The following figures show the trade between Italy and the United Kingdom in pharmaceutical articles during the last two years:—

Imports.		1890.	1889.
Acids	Cwt.	8,640	6,130
Potash and caustic soda	"	136,016	131,498
Alkaloids	Lb.	3,726	2,992
Oxides	Cwt.	17,344	19,310
Carbonates	"	59,766	92,770
Chlorides	"	76,182	71,249
Nitrates	"	10,554	20,711
Sulphates	"	238,142	126,310
Other chemicals	"	25,698	26,368
Bark	"	9,636	9,382
Gums and resins	"	21,444	29,048
Soap	"	9,514	8,842
Exports.		1890.	1889.
Olive oil	Cwt.	131,284	215,156
Orange essences	Lb.	229,754	249,196
Boric acid	Cwt.	31,050	26,694
Alkaloids	Lb.	5,480	8,450
Tartar and lees of wine	Cwt.	101,782	88,086
Orange and lemon juices	"	42,386	42,952
Liquorice, aloes, &c.	"	12,884	9,810
Soap	"	19,018	25,606

Olive Oil.

Turning to the amount of olive oil, the small amount lately sent out of the country is principally due to the deficient harvests of 1889-90, as the export to France varied but little in the last two years. Olive oil entering France from Italy is now subject to a differential duty of 15 frs. per quintal; but, taking the average cost of production

at 100 frs., and at 140 frs. for the finest qualities, such a duty, although nearly quadrupling that imposed under the general tariff, can scarcely be considered prohibitive, as is the case with the duty on wine.

The export of olive oil to France, which in 1886 touched 30 per cent. of the whole amount exported, diminished in 1890 to 23 per cent.

The finer oils made in Liguria and Lucca still maintain their superiority, and, considering how much more extensively the olive is now cultivated in Turkey, Greece, the Ionian Islands, Tunis, &c., Italy may be fairly satisfied with her export—in good years averaging some 600,000 quintals.

GENERAL TRADE NOTES.

INDUSTRIAL PROGRESS OF THE SOUTHERN STATES OF THE AMERICAN UNION.

A review of the industrial and agricultural progress of the Southern States of the American Union in the last 10 years, based on census statistics, is contributed by Mr. Porter, Superintendent of the Census, to the *Manufacturers' Record*. Mr. Porter says:—"The mineral development and the increase in manufactures during this period has been of such magnitude and of such importance as to seriously attract the attention of the world. The South is to-day producing as much coal, iron ore, and pig iron as the entire United States produced in 1870. To my mind the progress of the Southern States in the manufacture of steel will be as great during the next 10 years as it has been in the production of coal and pig iron during the past decade. The class of labour attracted to these rich mineral regions will be of a higher character than of the past; that is to say, there will be artisans and mechanics who will command a much higher rate of wages, and hence increase the consuming power of the South." In 1860 the best estimates that can be obtained, according to the superintendent, show that the Southern States produced less than 1,000,000 tons of coal, and in 1870 about 2,000,000 tons. In the year 1880, as shown by official data, this production has increased to 5,676,160 tons. According to the eleventh census returns the production in 1890 was 17,772,945 tons. This gives an output in the coal-producing States of the South in 1890 of more than twice the entire output of bituminous coal in the United States in 1860, and nearly 2,000,000 more tons than the total production of the United States in 1870.

These same States, the writer says, show far greater progress in the production of pig iron. The only one of these States producing pig iron in 1860 and 1870 was Tennessee, which in 1860 produced 13,741 tons; in 1870, 28,688, jumping to 70,873 in 1880, and in 1888 producing 267,931 tons. The entire production of all these States, including Tennessee, in 1880 was 397,301 tons, which had in 1890 increased to nearly 2,000,000 tons. The production of iron ore in these Southern States now almost equals the total production of the United States in 1870. As illustrating the immense development of these States in the production of coal and iron, the following table is given:—

	Production of the United States in 1870.	Production of the Central Southern States in 1890.
	Tons.	Tons.
Bituminous coal	15,000,000	17,772,945
Iron ore	3,163,839	2,917,529
Pig iron	1,860,000	1,780,999

MINERALS IN CANADA.

The following is extracted from the *Toronto Monetary Times* for the 15th May last:—

There has been issued at Ottawa a preliminary summary of the production of metals and minerals in the Dominion

for the year 1890. It is possibly subject to correction or addition, but the value placed upon the total is about the same as in 1889, viz., 19,000,000 dols., as compared with 15,000,000 dols. in 1888. The most notable feature in the statement here given is that the most valuable output among the metals appears to be that of nickel. At any rate, the quantity of nickel raised is put down at 1,640,240 lb., or 820 tons, the value of which, at 75 cents per pound, would be 1,230,180 dols. This result, however, we must regard as an approximation, since the companies producing nickel are chary of giving information to Government about their doings. We give the figures as we find them.

Production of Metals, 1890.—Gold, 65,011 oz., value 1,166,227 dols.; copper, 6,454,913 lb., value 968,241 dols.; nickel, 1,640,240 lb., value 1,230,180 dols.; silver, 400,687 oz., value 120,662 dols.; iron ore, 76,511 tons, value 155,380 dols.; iron pig, 21,772 tons, value 331,688 dols.; lead, 113,000 lb., value 5,085 dols.

If reliance is to be placed upon these figures, we showed a considerable falling off during the year in the production of iron. But there will be an improved tale to tell of 1891 in this respect, for New Glasgow, Londonderry, and Three Rivers will all have additions to make to the manufactured iron returns. The figures for the principal non-metallic minerals are as follows:—

Asbestos, 8,000 tons, value 1,039,651 dols.; bricks, 208,587 thousands, value 1,247,607 dols.; building stone, 360,001 cub. yds., value 336,168 dols.; coal, 3,117,661 tons, value 6,396,910 dols.; glass, value 537,130 dols.; petroleum, 765,029 barrels, value 902,734 dols.

Total non-metallic, 13,928,417 dols.; total metallic, 3,722,565 dols.; estimated value of mineral products not returned, principally structural materials, 1,349,018 dols. Total, 19,000,000 dols.

PRODUCTION OF OLIVE OIL IN SPAIN.

The following information respecting the production of oils in Spain is taken from the *Gazeta Mercantil*:—

The yield each year amounts to about 300,000,000 kilos, of oil, of which nearly half, or 147,600,000 kilos., represents the production of the provinces of Andalusia, Cordova, Seville, and Jaen.

Of the 49 Spanish provinces, including the adjacent islands, only 17 do not cultivate the olive. These are Alava, Burgos, the Canaries, Corunna, Guipuzcoa, Leon, Lugo, Orense, Oviedo, Palencia, Pontevedra, Santander, Segovia, Soria, Valladolid, Vizcaya, and Zamora. Further 14 provinces produce only the oil necessary for the consumption of their inhabitants; these are Alicante, Almeria, Avila, the Balearic Islands, Barcelona, Cadiz, Cuenca, Grenada, Guadalupe, Huesca, Logrono, Madrid, Navarre, and Salamanca. The latter produces the least oil, 137,000 kilos.

The province of Cordova produces the most, 55,200,000 kilos. The province of Seville produces 4,945,000 kilos., and Jaen 3,588,000 kilos.

There are consumed about 138,000,000 kilos, of oil in Spain, there only remains consequently an excess of 162,000,000 kilos. for exportation. The latter goes to South America, the Antilles, England, France, and Portugal. —*Board of Trade Journal*.

COAL DISCOVERY IN ASIATIC TURKEY.

The *Journal de la Chambre de Commerce de Constantinople* says that some coal mines have just been discovered at different places in the vilayet of Erzeroum. The mining engineer of the vilayet of Trebizond has been requested to go to Erzeroum, to examine these mines and to make a report.

LAVOISIER'S MEDAL.

The Société d'Encouragement pour l'Industrie Nationale has awarded its gold medal to M. Solvay for his share in the development of the ammonia-soda industry. This medal is only awarded in each sixth year, Ste. Claire Deville, Weldon, and Michel Perret being former recipients. The distinction is the greater as Schloesing, who is usually regarded by the French as the discoverer of this process, is himself a member of the committee.—*Industries*.

PRODUCTION OF MANGANESE ORES IN THE UNITED STATES SINCE 1880.

The production of manganese from 1880 to 1889, inclusive, has been as follows:—

States.	1880.	1881.	1882.	1883.	1884.
Virginia	2,661	3,295	2,082	5,335	8,980
Arkansas	100	175	400	800
Georgia	1,800	1,200	1,000
Other States	300	300	575	400	400
Total	4,761	4,895	4,632	6,135	10,180

States.	1885.	1886.	1887.	1888.	1889.
Virginia	18,745	20,567	19,835	17,546	14,616
Arkansas	1,184	3,316	5,651	4,312	2,528
Georgia	2,580	6,041	9,924	5,568	5,208
Other States	450	269	14	1,672	1,575
Total	23,258	30,193	34,524	29,498	23,927

This table shows the production of what may be strictly regarded as manganese ores in the classification above given. It has been impossible in some cases to separate the manganese and manganiferous ores which are the product of a given mine, but where the total production of State or mine averages more than 44·252 per cent. of metallic manganese its production is regarded as manganese ores.—*Eng. and Min. Journal*.

MINERAL PRODUCTION OF RUSSIA IN 1889.

To the courtesy of Mr. W. A. Abeg, of St. Petersburg, we are indebted for the following statistical table of the mineral production of Russia in 1889, together with that of 1888.

	1888.	1889.
	Pounds.*	Pounds.
Gold (Siberia and Lapland)	2,118	2,272
Platinum (Ural)	166	68
Silver (Altai, Baikal, Caucasus)	924	846
Ural, Altai, Baikal, Caucasus	49,000	35,314
Tin (Ural)	1,200	721
Spelter (Poland)	236,000	149,318
Copper (Ural, Siberia, Poland, Caucasus, and Finland)	281,000	377,571

THE SPANISH DRUG TRADE.

The declared value of the imports of drugs and chemical products into Spain during the first four months of 1891 was 19,194,032 ptas., against 19,039,215 ptas. and 15,095,080 ptas. respectively in the corresponding periods of 1890 and 1889. The exports of some of the principal Spanish products of pharmaceutical interest have been as follows:—

	January—April.		
	1889.	1890.	1891.
Quicksilver	Kilos. 1,266,745	Kilos. 659,347	Kilos. 1,206,025
Liquorice, in pipe	637,331	625,754	547,371
Liquorice, in paste	162,082	278,102	249,045
Cream of tartar	151,571	129,322	180,053
Anise	212,306	205,576	249,976
Olive oil	12,210,094	5,995,487	1,543,187
Saffron	9,839	12,157	11,930

THE GERMAN ALKALI INDUSTRY.

The managing director of the German alkali works, "Rhenania," in an article in a recent German chemical journal, gives an interesting account of the German alkali industry since 1873. In that year the duties on soda salts were considerably reduced, and immediately the prosperity of the German alkali industry began to decline. This decay continued until 1879, when the tariff was revised in a protective sense. The effects of the increased duties made themselves felt almost at once. In 1878 the German soda production amounted to about 42,500 tons, while about 27,500 tons were imported from abroad. Since 1878, however, the total production has risen to 195,000 tons, of which 28,450 were exported. Germany now exports more than she imports of all the principal soda salts, except bicarbonate of soda. In 1881, five years after the adoption of protective legislation, soda ash was the first article to show an excess of exports over imports; soda crystals followed in 1886, and caustic soda in 1890.—*Ibid*.

THE STASSFURT POTASH SALTS INDUSTRY DURING THE YEAR 1889.

G. Borsche. Chem. Ind. 13, 492—193.

Another works, viz., the Deutschen Solvay-Werke at Bernburg, has been added to those works belonging to the Syndicate, making the total number of these works, eight. During the coming year still another potash works (at Thiele) will come into operation.

The general state of the industry during 1889 had remained unchanged.

During that year were produced for working up into concentrated potash salts:—

7,392,500 meter-centners of carnallite,
1,275,000 meter-centners of kamit, including shonite and sylvinite.

The output of potash salts was—

1,237,500 meter-centners of potassium chloride of 80 per cent.,
161,000 meter-centners of sulphate salts (potassium sulphate and potassium-magnesium sulphate),
22,000 meter-centners of potash manure salts, containing 20 per cent. and upwards of potash.

Up to this year the United States has been the chief market for potassium-magnesium sulphate, because potassium sulphate was charged with an *ad valorem* duty of 20 per cent. But during 1889, owing to the coming into force of the new Customs tariff, and the remission of the duty on potassium sulphate, the export of the latter to the States has largely exceeded that of potassium-magnesium sulphate.

Prices have remained unaltered.

The yield of kainit for agricultural purposes in 1889 was 2,632,800 meter-centners of which—

	Meter-centners.
Germany took.....	1,501,700
America.....	716,700
Other countries.....	414,400

There was also worked for agricultural purposes—

268,000 meter-centners of carnallite.
91,500 meter-centners of kieserite.

The sale of kieserite in lumps (magnesium sulphate) is a monopoly held by the Syndicate. The output of this was 318,200 meter-centners. The output and price of magnesium chloride, magnesium sulphate (Epsom salts), Glauber salts, and bromine are also regulated by the combination.

The recovery of chlorine and hydrochloric acid from magnesium chloride is still confined to the two works that have heretofore worked these processes. A further patent for the direct recovery of chlorine from magnesium chloride has been worked out by de Wilde of Brussels.

The proposed ammonia-magnesium method for making potash, has, on a large scale, been temporarily discontinued owing to technical difficulties, which necessitate further experiment.

Engel's patent for making potash by means of magnesia has passed into the hands of the Salzbergwerks Neu-Stassfurt, which has obtained a concession of a site for erecting works for carrying out the process on a commercial scale.—H. S. P.

THE GERMAN ULTRAMARINE INDUSTRY.

Dr. Kraushaar. Chem. Ind. 13, 512.

The low prices of ultramarine which have held for more than 10 years have led to the formation of a limited liability company, which has taken over nearly all the ultramarine works of Germany. Arrangements have been made with the few works that have not joined this company, by which either the whole of their make is sold to the company, or some other device has been agreed upon, which gives a guarantee that the operations of the new company will not be interfered with. A consequence of this combination has been a considerable rise in the price of ultramarine.

—H. S. P.

THE PRESENT STATE OF THE SODA INDUSTRY, ESPECIALLY OF THE LEBLANC PROCESS.

Chem. Zeit. 15, 73—74.

During the last five years the English as well as the German soda industry has suffered from over-production caused by the enormously increased quantities manufactured by the ammonia process. A number of establishments working the Leblanc process have consequently had to limit or even to stop the manufacture, until at last the English Leblanc manufacturers have recognised the necessity of preventing a further reduction of prices. Germany's export during the last few years has greatly increased. Last year it amounted to 21 per cent. of the total production of German soda. Such was the state of affairs when the United Alkali Company, Limited, was founded last year, and it may be expected that the organisation of this great enterprise will permanently improve the English soda industry. The Austrian soda manufacturers have likewise succeeded in forming a syndicate, and it is expected that this will be of considerable advantage to the trade. In order to minimise German competition, the prices charged near the German frontier are lower, and this, together with the high Austrian import duty, will prevent large sales of German soda there. In face of these facts the author recommends the formation of a German syndicate, in order to derive the full benefit from the present position of the industry. In would in this case of course be necessary to limit production to a certain extent if prices are to be improved. A central office for sales like that in Vienna is strongly recommended, such as was tried unsuccessfully, four years ago by the German Solvay works at Bernburg. In Germany the prices of calcined and crystallised, as well

as of caustic soda generally, rose towards the end of last year, and it is expected that at the end of the current year a further rise will take place. On the other hand, the prices of bleaching powder went down in spite of the convention, and a further fall is expected. As regards the different bleaching powder processes, the magnesium chloride and the electrolytic methods have not been worked long enough for a conclusion to be formed of their commercial value. But it is proved beyond doubt that the Deacon process—which has been introduced into Germany at Rheinlan in conjunction with the Hargreaves process—is a success, the bleaching powder manufactured in this way being considerably cheaper than that obtained by the Weldon process. The author is of opinion that if the Leblanc manufacturers succeed in recovering the sulphur by the Chance process they will be able to compete with ammonia soda; and the manufacture of bleaching powder by the Deacon process, as just described, will be a further advantage. The magnesium chloride process for the manufacture of bleaching powder, which has been introduced at Stessfurt, seems to require an expensive plant, as the costs of the latter are stated to be double those of the Weldon plant, and it is said that there are difficulties connected with the manufacture in hot weather. The electrolytic system has been introduced at Griesheim, but nothing is as yet known of the results. It is said, however, that the plant of this system also is much more expensive than that of the Weldon process. In spite of the increased manufacture of bleaching powder in Germany during the last year, a good quantity has been imported; and it seems that there is greater over-production of it in England than in Germany. The direct consequence of the new processes was that less bleaching powder was manufactured by the Weldon process and less hydrochloric acid used, the price of which went down in consequence, notwithstanding the convention. The author draws the general conclusion that the prospects of the German Leblanc soda manufacture can be satisfactory only if conventions, comprising all articles concerned, are formed.

HOW TO PACK DRUGS AND CHEMICALS FOR EXPORT.

C. Monheim. Chem. Zeit. 15, 41—42.

The following suggestions will be found of practical value:—

1. Salts should be put in stoppered glass bottles or packed in casks, if sent in large quantities. Casks used for hygroscopic salts should be lined with oil cloth or parchment paper. Salts should never be packed in tin boxes or in paper only.
2. The glass stoppers of all bottles containing either liquids or dry substances should be greased with a little vaseline in order to avoid any difficulty in removing them.
3. Parts of plants, such as leaves, roots, &c., should be packed in sacks, and these again in cases; very delicate drugs in tin boxes. Vegetable powders should be packed in hermetically closed glass bottles or tin boxes. Drugs which occupy much space should be pressed as much as possible before being packed, especially if the shipping freight is calculated according to the bulk of the goods.
4. Boxes and cases should be lined with zinc, or where this is too expensive a strong and good oil cloth will usually be sufficient.
5. Although the utmost care is necessary in packing, yet packing materials such as hay, straw, &c., should be used as sparingly as possible, as duty has usually to be paid for the weight of these as well as for the goods themselves.
6. Cases should be secured by iron bands, and it is always desirable that the weight and volume of cases should be as small as possible.
7. Acids, caustic, or inflammable substances must be packed according to the regulations of the different railways by which they are transmitted prior to shipment. As a rule stone bottles are best for acids and ammonia, and glass or tin vessels for volatile substances. All these should be closed by corks saturated with paraffin, and then wrapped in sail cloth which, with the string securing it, should also be soaked in paraffin.

8. Acetic acid may be safely conveyed from place to place in casks of 5 to 10 gallons capacity.

9. Liquid ammonia should never be put into iron vessels.

10. Vessels containing volatile substances should never be quite filled.

11. As acids and caustic and inflammable substances are conveyed on the decks of sailing vessels only, the cases containing them should be well closed, and the address, mark, number, &c., be such as will resist sea water.

12. Liquids should not be packed in the same case with dry substances.

13. Valuable or expensive chemicals, such as ethereal oils and essences, should be packed in strong tin vessels and closed with corks saturated with paraffin as before described.

14. The weights and measures of the country to which the goods are sent should always be used to avoid loss and inconvenience.

15. Besides observing these rules for packing, consignors of goods should be thoroughly acquainted with the Customs tariffs and regulations of the countries to which they are sending, as pecuniary loss and inconvenience may occur from ignorance of them. For instance, if a case contains various substances, the duties on which are different, it is usual in some tariffs to calculate the duty of the whole of the contents of the case or at least of the packing materials at the highest rate. The importance of packing together goods upon which the Customs tariffs are similar is self-evident from this.

16. In cases of urgency small quantities of any substance suitable for such transmission, e.g., quinine, antipyrine, salicylic acid, &c., may be sent as patterns without value, and thus avoid the delay caused by the Customs office.

H. S.

NOTES FROM BAKO.

Chem. Zeit. 15, 228.

Ragosin's experiments for producing inflammable oils from heavy sorts and residues of naphtha, gave the following results. The specific gravities of the materials used were 0.920-0.935. The distilling apparatus was used without pressure, and 10 distillations could be made in 24 hours. The materials gave 55 per cent. of inflammable oils of a yellow colour, and better than ordinary kerosene, 22 per cent. of tar and 7 per cent. loss. The flashing points of the oils obtained were very high. Having obtained these favourable results, Ragosin intends to erect a factory for the working of his process. Silver ores have been discovered near Lagansk, containing 30 per cent. of silver. A company has been formed to exploit the mines. Although the Russian Government has declined to lay naphtha pipes from Bako to Batoum, yet it does not seem disinclined to support the idea of making Batoum the centre of the Caucasian kerosene trade, which would be considerably improved thereby. It is reported that foreign capital is to be invoked to lay the aforesaid naphtha pipes.—H. S.

MINERAL BLACK.

A manufactory of mineral black and tripol has been established at La Faye by M. Viorat, who produces annually some 100,000 kilos. of the black, and about half the quantity of the tripol. Mineral black is the residue of thorough mementation of schist (schist) in closed vessels. It is thus calcined for eight hours, and what remains is gathered in closed metal boxes, and then cooled without being exposed to the air. It is then carefully sorted and ground to fine powder. This substance, known as "Auvergne black" is said to be obtaining popular favour for ship painting, blacking, printing ink, varnish, and other purposes for which an intense black is required. *Chemist and Druggist.*

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND
MACHINERY.

APPLICATIONS.

8546. J. C. Mewburn.—From The Maschinenfabrik Grevenbroich, Germany. *See Class XVI.*

8547. W. H. Beck.—From G. Moreau, France. *See Class II.*

8551. J. H. Day. Improved apparatus and process for spreading viscous substances. Complete Specification. May 19.

8653. W. W. Horn.—From S. C. Thrall, United States. An improved apparatus for making extracts. May 20.

8697. L. Lobet. Improvements in carburetted apparatus. May 21.

8809. W. J. Mirrlees.—From H. T. Varyan, United States. Improvements in evaporating and distilling apparatus. Complete Specification. May 23.

8823. A. McDougall. Improvements in covering lead surfaces to protect water and other liquids from contamination with the dissolved metal. May 25.

8863. H. H. Lake.—From Lacombe and Co., France. Improvements in rheostats. May 25.

8910. J. Toussaint. A novel combination of ingredients for making crucibles, pots and other articles capable of resisting heat. May 26.

9147. A. W. Ellis. Improvements in filtering apparatus. June 1.

9181. J. Dawson and J. W. Hampson. An improved construction of refrigerator or cooling pan for chemical and other purposes. June 1.

9187. E. J. Mills and C. J. Ellis. An improved means and method of closure for the regulation of gaseous pressures. June 1.

9310. A. J. Boulton.—From A. Klönne and F. Bredel, United States. Improvements in the setting and heating of retorts. June 2.

9311. W. P. Thompson.—From J. A. Bowden, United States. Improvements in filters. Complete Specification. June 2.

9344. W. P. Thompson.—From J. A. Bowden, United States. Improvements in filtering apparatus. Complete Specification. June 2.

9348. A. J. Bonli.—From A. Kloune and F. Bredel, United States. Improvements in apparatus for charging retorts. June 2.

9354. J. Zubr. Improvements in retort furnaces. Complete Specification. June 2.

9378. F. J. Quiry. Improved filter bricks, or bricks which will allow of the flow of liquids or gases through structures formed of such bricks. June 3.

9434. J. Menzies. A new composition, and the process for manufacturing the same. June 3.

9573. G. L. J. Wells. Improvements in or appertaining to filtering apparatus, applicable for the treatment of ammoniated brine and other materials. June 5.

9596. J. J. Barlow. See Class VII.

9774. C. D. Martin. Improvements in valves for chemical liquids. June 9.

9879. D. Barr. Improved apparatus for mixing and effecting the circulation of liquids or pulverulent substances within vessels. June 10.

9922. W. Luzzi. Improvements in the treatment or purification of graphite, to render it suitable for industrial purposes. June 11.

10,012. A. Liwentaal. Improvements in and relating to apparatus for producing steam by liquid fuel. June 12.

COMPLETE SPECIFICATIONS ACCEPTED.*

1890.

9548. J. Foster. Apparatus for evaporating solutions containing salts, and for other liquids. June 17.

9604. W. E. Smith. Apparatus for burning liquid fuel. June 17.

10,888. J. H. R. Dismore. Apparatus for drying granular substances. June 3.

11,529. A. Chapman and S. Vickers, jun. Evaporating apparatus specially adapted for the extraction of salt from brine. May 27.

12,004. L. Menetrel. Apparatus for washing, lixiviating, or extracting purposes. June 10.

1891.

3836. H. E. Newton.—From C. F. Worthington. Surface condensers. May 27.

3902. J. F. H. Gronwald and E. H. C. Oehlmann. Sterilising apparatus. May 27.

6374. J. Goumet. Ozonising apparatus. May 27.

6797. W. Werschm. See Class VIII.

7205. The Gaseous and Liquid Fuel Supply Co., Ltd., and B. H. Thwaite. Apparatus for inducing the flow of, and injecting and spraying, gaseous and liquid fluids. June 3.

8467. R. D. Gates. Concentrating apparatus. June 17.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

8547. W. H. Beck.—From G. Moreau, France. Improvements in or connected with the production and drying of compressed air, and its application to useful purposes. Complete Specification. May 19.

8641. G. Chabaud. Improvements in the agglomeration of lignite. May 20.

8697. L. Lobet. Improvements in carburettine apparatus. May 24.

9104. E. W. Harvey and C. W. Aldred. Improvements in the manufacture of electric light carbons. May 29.

9171. E. Ludmann. Improvements in process of extraction of gases from fluids. Complete Specification. June 1.

9180. B. H. Thwaite. Improvements in methods of storing inflammable spirits or highly volatile hydrocarbons. June 1.

9366. B. Gibbons and W. P. Gibbons. Improvements in apparatus for charging inclined gas retorts. June 3.

9398. P. van Gelder. Improvements in separating smoke or soot from air or other gases, and in utilising the air or gases so purified. June 3.

9457. J. H. Parkinson. Improvements in obtaining or separating oxygen from atmospheric air, and in apparatus therefor. June 4.

9716. J. F. Allen. Improvements in the manufacture of illuminating gas. Complete Specification. June 9.

9729. M. Pickford. The manufacture of a slow combustion fire-lighter. June 9.

9781. L. Labois. Improvements relating to the treatment of sulphur ores, crude sulphur, ozokerites, heavy oils of petroleum, and other materials for extracting, purifying, or refining purposes, and to apparatus for use therein. June 9.

9796. H. H. Lake.—From The Standard Coal and Fuel Co., United States. An improved compound for treating fuel. Complete Specification. June 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

8373. E. W. Walker. Method and apparatus for manufacturing gas. June 3.

9651. W. Lee and C. Gumbart. Treating peat for production of fuel and by-products. May 27.

10,831. L. van Vestrant. Means and apparatus for charging inclined gas retorts. June 10.

11,195. W. W. Staveley. Treatment of crude blast-furnace or coke-oven oils, and application of the products. June 3.

11,581. F. J. Rowan and H. Armour. Retorts for distilling shale or other oil-yielding minerals. June 10.

11,757. J. Laing. Apparatus for destructive distillation of mineral oils. May 27.

1891.

2459. J. A. Soetjé and J. C. A. Kahl. Manufacture of peat briquettes, peat coke, and peat coke briquettes. June 3.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

APPLICATION.

9052. W. P. Thompson.—From P. Kautze, Germany. Improvements in the manufacture of ammonia and tar from nitrogenous organic substances, and in apparatus relating thereto. May 28.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

10,976. T. H. Davis and A. H. Davis. See Class XIII.

11,757. J. Laing. See Class II.

* See Note * on previous page.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

8702. B. Wilcox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. The manufacture and production of colouring matters derived from anthraquinone and alizarine blue. May 21.

9280. J. Frost and E. C. Kayser. Improvements in the manufacture of azo-colouring matters, and in their application for dyeing and printing. June 2.

9636. B. Wilcox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the production of black azo-colours upon fibres. June 6.

9943. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Production of blue colouring matter. June 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

10,448. Brooke, Simpson, and Spiller, Limited, and A. G. Green. Production of new azo-colouring matters. May 27.

10,802. O. Imray. — From The Farbwerke vormals Meister, Lucius, and Brüning. Production of novel colouring matters for wool-dyeing and printing. May 27.

12,356. J. V. Johnson.—From The Badische Anilin und Soda Fabrik. Manufacture of colouring matters from dihydroxybenzoic acid. June 10.

12,386. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. Production of new materials for the preparation of dyestuffs. June 10.

14,116. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. Production of new amido-azo compounds and azo-dyes therefrom. June 10.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

8644. C. Stephens. Improved means for dampening, drying, dyeing, starching, or chemically treating paper, silk, felts, and other like fabrics. May 20.

8776. P. V. M. Raabe. Improvements in the treatment of vegetable textile fibres for the manufacture of yarns and fabrics. May 23.

9696. W. Whitaker and G. E. Donisthorpe. Improvements in the treatment, preparation, and application of certain fibrous materials suitable for spinning yarns for the manufacture of woven, felted, and other textile fabrics; applicable also to other useful purposes. June 8.

10,017. F. J. H. Sampson. Improvements in the treatment of rhea to obtain fibre therefrom, and in apparatus to be used in such treatment. June 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

2827. A. J. Boulton. Manufacture or treatment of textile fabrics. May 27.

12,576. J. Sutcliffe and J. Greenwood. Treatment of yarn for weaving. June 3.

1891.

6663. A. George. Cleansing wool and similar substances. May 27.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

8538. J. W. Selanders and W. Turnbull. An improvement in dyeing fabrics. May 19.

9228. E. A. Marchand. A process of bleaching vegetable and animal fibres and tissues by means of alkaline permanganates; and the economical production of such permanganates. June 1.

9413. C. E. Cross, E. J. Bevan, and C. Beadle. Improvements in dyeing jute and other vegetable fibres. June 3.

9470. R. Lanham and D. Gulland. An improved method of and apparatus for embossing, colouring, and printing upon paper or other suitable material. June 4.

9554. J. Horrocks. Improvements in bleaching raw cotton, and in machinery or apparatus to be used in parts of the process. June 5.

9995. J. Frost and E. C. Kayser. Improvements in the production of dyes on textile fibres and other like materials. June 12.

COMPLETE SPECIFICATION ACCEPTED.

1890.

6612. R. T. West. Expediting and improving the process of bleaching linen, cotton, and other yarns in the hank. June 10.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

8530. G. H. Hedley. The manufacture of sulphate of soda, hydrochloric acid, and red oxide of iron. May 19.

8574. A. Vogt. Improvements in the manufacture of carbonate of soda and carbonate of potash. May 19.

8692. F. M. Lyte. Improvements in the production of caustic alkalis, alkalines, carbonates and other products. May 21.

8810. M. Netto. Improvements relating to the separation of the so-called fished salts obtained in the manufacture of caustic soda. May 23.

8814. A. E. M. L. Paillard. A method of manufacturing and regenerating salts of peroxide of iron. May 25.

9332. Comte T. S. de Dieheim Brochocki. Improvements in the manufacture or production of chlorine compounds for bleaching. June 2.

9458. J. H. Parkinson. Improved process of treating a permanganate of potash or soda to produce a spongy porous mass. June 4.

9561. W. Walker. An improved method of recovering carbonic acid gas from lime-kilns and furnaces, and apparatus in connexion therewith. June 5.

9575. D. Rylands. Improved process or arrangements for the manufacture of carbonic acid gas. June 5.

9596. J. J. Barlow. Improvements relating to the recovery and utilisation of waste heat from black ash, soda ash, salt cake, and other solid and highly heated substances produced in alkali and chemical works, and of apparatus therefor. June 6.

9616. E. Lohmann. Improvements in process for production of carbonic acid. Complete Specification. June 6.

9732. D. Rylands. Improvements in the manufacture of carbonic acid gas, and in tubes for containing the same. June 9.

9781. L. Labois. See Class II.

9785. W. Walker. Improvements in apparatus for obtaining silicates for making glass, and for the production of hydrochloric acid. June 9.

9786. W. Walker. An improved method of recovering carbonic acid gas from lime-kilns and furnaces, and apparatus in connection therewith. June 9.

9947. A. T. Hall. Improvement in the treatment of waste liquors from metallurgical processes to obtain sulphurous or sulphuric acid and zinc. June 11.

9948. A. T. Hall. Improvements in the treatment of waste liquors from metallurgical processes to obtain sulphurous or sulphuric acid and oxide of iron. June 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

3087. I. G. Lawrence.—From S. Pick. Apparatus for evaporating liquors containing salts, and for separating such salts when rendered insoluble by evaporation of the liquors. June 3.

9198. W. L. Wise.—From The Chemische Fabrik Buckau Aetien-gesellschaft. Treatment of impure or waste potassium salts for the manufacture therefrom of soda, potash, hydrochloric acid, magnesia, calcium sulphate, and sulphur or sulphuric acid. June 10.

11,296. A. G. Haddock and J. Leith. Manufacture of alkaline carbonates and by-products, and arrangement of plant therefor. May 27.

11,529. A. Chapman and S. Vickers. See Class I.

11,545. F. M. Lyte and J. G. Tatters. Conversion of hard-burnt into soft-burnt magnesia. June 3.

11,638. T. Elliot. Producing sulphate of calcium. June 3.

11,979. W. B. Giles, F. G. A. Roberts, and A. Boake. Production of acid sulphates. June 10.

12,661. R. Dempster and J. Dempster. Apparatus connected with the manufacture of sulphate of ammonia. June 17.

18,990. J. Greenwood. Production of chlorine and caustic soda, and apparatus therefor. May 27.

1891.

2134. J. Greenwood. Manufacture of caustic soda. May 27.

2343. T. G. Webb. Apparatus for concentrating sulphuric acid. June 10.

5519. M. W. Bychkgy, C. J. Everett, and C. A. Collins. A new alkaline magnesium compound. June 17.

7362. C. Kellner. Apparatus for recovering sulphurous and used in the manufacture of paper pulp from wood. June 3.

7757. O. H. Fish. Furnaces for burning sulphur. June 10.

VIII. GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

8528. D. Rylands. Improvements in furnaces for glass melting and for similar purposes. May 19.

8848. C. W. Fox, I. Robinson, and W. H. Gritton. Improvements in or appertaining to the manufacture of glass. May 25.

9220. H. Godwin and W. Hewitt. Improvements in or applicable to fender, hearth, wall, and other tiles. Complete Specification. June 1.

9377. F. J. Query. Improvements to be employed in the manufacture of certain kinds of earthenware articles. June 3.

9412. W. James. An improved method of ornamenting glass. Complete Specification. June 3.

9745. L. Lederer. Process for the production of coloured designs and coloured writing on mirrors. Complete Specification. June 9.

9785. W. Walker. See Class VII.

9960. D. Rylands. Improvements in furnaces for glass melting and for similar purposes. June 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

11,651. D. Rylands and A. Hesselbee. Manufacture of glass tubing. May 27.

12,506. T. Webster, sen., and T. Webster, jun. Manufacture of earthenware pots, jars, &c., whole or in section. June 17.

1891.

6797. G. Weigelin. Methods and appliances for drying moist material (bricks, pipes, flags, &c.) by artificial heat. May 27.

7908. J. E. Bousfield.—From F. Schultz. Manufacture of stove tiles, mouldings, rosettes, &c., and apparatus therefor. June 17.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

8567. O. Huray.—From W. Schlening, Germany. Improvements in the manufacture of artificial stone. May 19.

8875. J. J. Mead. An improved lime-grinding mill. Complete Specification. May 26.

9189. W. Corbould. Improvements in manufactured whitew. June 1.

9319. W. P. Thompson.—From J. Petrus von Balgooy, Holland. See Class XIII.

9561. W. Walker. See Class VII.

10,080. A. Schofer. Improved apparatus for drying cement, clay, and other materials for burning or calcining. Complete Specification. June 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

8108. F. Sarg. Concrete for construction of vaults, roofs, arches, &c. May 27.

10,918. N. W. Curtis and A. E. Carey. Apparatus for crushing and mixing material for the manufacture of cement. June 10.

11,245. S. McDougall. Blocks, tiles, &c. for pavements, floors, and steps. May 27.

12,640. F. F. von Ainhach. Production of stony polychrome decorations. June 17.

17,453. M. Hirsch and H. Reinisch. Macadam pavement. June 17.

1891.

5719. A. J. Boulh. From L. Grote. Artificial stone. June 17.

6389. R. A. Cheesbrough. Preservation of wood and non imbedded in the earth. June 10.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

8529. D. C. Bateman. Improvements in the method of and apparatus for hardening and tempering steel wire. May 19.

8688. C. T. J. Vautin. Improvements in the method of and means for extracting gold from ores, or from materials containing it. May 21.

8689. C. T. J. Vautin. An improved amalgamator. May 21.

8818. D. Rennie. Improvements in furnaces for melting iron, steel, and other metals. May 25.

8819. W. Bevan. An annealing apparatus to be applied to heating furnaces for iron, steel, or metal sheets and plates. May 25.

8837. The Rovelto Syndicate, Lim., and J. C. Howell. Improvements in apparatus for use in obtaining copper. May 25.

8881. F. J. Page and H. A. Anderson. Improvements in the art of soldering aluminium. Complete Specification. May 26.

8904. G. G. M. Hardingham.—From G. Ashcroft, Australia. Improved means applicable for use in the treatment of ores and other compounds for the extraction of the precious metals by amalgamation. May 26.

9013. A. M. Clark.—From The Deutsche Gold und Silber Scheide-Anstalt, vormals Roessler, through Wirth and Co., Germany. An improved process for desilverising argentiferous lead. May 27.

9061. R. R. Gubbins. Improvements in cleaning scrap iron. May 28.

9143. A. Torkington.—From N. K. Morris, United States. Improved apparatus for use in the manufacture of lead fibre. Complete Specification. May 29.

9219. H. Niewerth. Improvements in obtaining metals, half-metallic elements, and other minerals. June 1.

9341. J. H. Rogers. Improvements in apparatus used in the manufacture of tin andterne plates. June 2.

9342. J. H. Rogers. Improvements in the manufacture of tin andterne plates. June 2.

9417. J. O. Day. Improvements in alloys and compositions for use in covering or coating surfaces of iron and steel, and the surfaces of other materials, in order to prevent corrosion and fouling thereof when submerged. June 3.

9468. J. G. H. Batchelor and C. T. Batchelor. Improvements in the means of separation and recovery of tin and iron from tin scrap, hard-head, and other tin refuse. June 4.

9686. A. Longsdon.—From F. Asthower, Germany. Improvements in compound armour plates. Complete Specification. June 8.

9708. C. J. Fauvel. An improved furnace for the treatment of refractory ores. June 8.

9757. R. Heathfield. Improvements in the process of coating or cleaning metals. June 9.

9784. W. Noad, C. Minns, and P. H. Stevens. An improved process of or means for extracting or recovering metals from their ores or other metal-bearing bodies. June 9.

9923. H. J. Allison.—From A. Burnstine, United States. An improved process for treating the products of zinc ores. June 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

8759. J. von Langer. Manufacture of iron and steel. June 3.

9123. A. Danber. Making pig iron, wrought iron, cast steel, and rough steel. June 10.

11,649. A. Jepson. Manufacture of iron and steel castings. June 3.

11,690. P. U. Askham and W. Wilson. Electro-magnetic separators for extracting metal from slag and the like. June 10.

12,200. W. Beatson. Method and apparatus for recovering tin from waste tinned iron or steel. June 17.

12,621. A. M. Clark.—From W. G. Horgan. Fluxes or solutions for coating metals with lead. June 10.

12,626. L. Mond. Manufacture of nickel. June 17.

12,666. W. Brazell. Annealing tin andterne plates. June 17.

13,174. W. L. Wise.—From L. Benckhaus. Process for roasting ores and metallic compounds. June 10.

18,508. J. Johnson.—From J. W. Langley. Aluminium alloys and manufacture thereof. June 3.

18,516. F. H. Molesworth. Construction of rotary furnaces for the calcination of sulphide and other ores. June 3.

1891.

3348. B. C. Tilghman and R. A. Tilghman. Manufacture of chilled iron globules. June 10.

4695. W. A. Baldwin. Process and apparatus for alloying metals. June 10.

7777. W. P. Thompson.—From F. J. Clamer. Coating certain metals or metal articles with other metals or alloys. June 17.

8127. W. G. Richards. Process and moulds for making castings. June 17.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY

APPLICATIONS.

8573. J. V. Johnson.—From J. Weir, United States. The manufacture and production of hydrocarbon products or compositions for use for insulating or other purposes. Complete Specification. May 19.

8648. E. Bazin. Improvements connected with the use of compressed air for producing electric light and cold. Complete Specification. May 20.

8735. E. W. Berdoo and G. M. Shum. Improvements in electrical storage batteries or accumulators. May 22.

8808. W. J. Green. Improvements in and relating to electrical batteries. May 23.

8845. R. Haddan.—From I. Cabanyes, France. Improvements in galvanic batteries. May 25.

8872. J. F. Bennett and E. P. Hides. Improvements in galvanic batteries. May 26.

8941. A. J. Boulton.—From E. E. Ries, United States. Improvements in method and apparatus for electrical hardening and tempering. Complete Specification. May 26.

9079. C. Hoepfner. Improvements relating to the electrolytic extraction of metals and to the electrolysis of other substances. May 28.

9627. C. D. Abel.—From R. J. Gulcher and the Firm of J. Pintsch, Germany. Improvements in thermo-electric batteries. Complete Specification. June 6.

9628. D. G. FitzGerald. Improvements in or connected with negative elements (positive electrodes in charging secondary cells) of voltaic batteries. June 6.

9629. D. G. FitzGerald. Improvements in or relating to the negative elements (positive electrodes in charging secondary cells) of voltaic batteries. June 6.

9652. A. Watt. Improvements in the production of copper tubes by electrolysis. June 8.

9683. T. J. D. Rawlins and A. Walker. Improvements in electric primary batteries. June 8.

9689. V. Jeanty. Apparatus for supplying depolarising or other liquids to a series of electric batteries. June 8.

9734. W. Aldred. Improvements in dynamic-electric machines. June 9.

9762, S. C. C. Currie. Improvements in secondary or storage batteries. Complete Specification. June 9.

9791, J. Greenwood. Improvements relating to carbon electrodes for electrolytic and other purposes. June 9.

9803, W. J. Engledue. An improvement in galvanic batteries. June 9.

9928, G. A. South. Improvements in galvanic batteries. Complete Specification. June 11.

9938, The London Metallurgical Co., Ltd., and S. O. Cooper Cables. Improved apparatus for consolidating metals during the process of being deposited from an electrolyte. June 11.

10082, P. Jablonkoff. An improvement in voltaic batteries. June 13.

10090, L. Graham. An improved process for the electrolytic production of aluminium. June 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

13,553, C. A. Faure. Production of electricity, and means thereof. June 3.

19,912, W. P. Thompson. — From F. Marx. Electrochemical formation of chlorine and chlorine compounds. May 20.

1891.

5637, R. W. Barker. — From M. G. Farmer. Electric converters. June 10.

7168, G. Wester. Voltaic cells. June 3.

7715, G. A. Washburn. Storage batteries. June 10.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

9434, H. H. Lake. — From La Societe Anonyme des Parfums Naturels de Cannes, France. Improvements relating to the purification of fatty substances. June 3.

9991, A. Siebel. Improvements in the manufacture of oil-soaps. Complete Specification. June 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

9476, H. H. Lake. — From F. de la Croix. Apparatus for desecating and sterilising waste animal substances, and extracting fat therefrom. June 3.

12,000, L. Walton. Oxidising and drying vegetable oils. June 10.

12,373, L. Ross. Manufacture of saponifiable matter from wool fat. May 27.

13,631, C. A. Fouché and J. C. Labrousse. Production of odourless wool grease. May 27.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

8510, H. Pimington. Improved process of manufacturing lead sulphate from metallic lead. Complete Specification. May 19.

8610, A. Gutensohn. An improved method of producing lead dust, and of converting the same into white lead. May 20.

8713, T. Simmons. A washable and varnishable substitute for oil paints and distempers. May 22.

9193, R. Jacks. — From G. Sharp, Peru. A new or improved composition for coating ships' plates and the like. June 4.

9231, R. Haddan. — From A. Grammont, France. A method of and apparatus for the purifying of gutta-percha. Complete Specification. June 1.

9267, W. B. Lawson and H. Schofield. An improvement in the manufacture of black-lead blocks. June 2.

9319, W. P. Thompson. — From J. Petrus van Balgooy, Holland. Improved process and compositions for coating walls and similar surfaces to prevent the penetration of damp. June 2.

9526, L. Labois. Improvements relating to the manufacture of white lead, and to apparatus for use therein. June 5.

9589, R. D. Burn. A new and improved paint or composition named "Litholine," for preserving the surface of iron and steel ships and other structures. June 6.

9747, H. Beck. — From E. Schaal, Germany. Improved manufacture of hard neutral resins as substitutes for natural resins, such as copal, amber, and the like. Complete Specification. June 9.

9851, C. Boothby and W. Mackeay. The manufacture of chromate of lead. June 10.

9932, W. C. Hayne. Improvements in the manufacture of fire-proof paint. June 11.

10,036, C. Calot. A new or improved varnish. June 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

10,976, T. H. Davis and A. H. Davis. Purifying coal tar, to render same a suitable paint or coating for iron or steel. June 17.

11,602, G. Bischof. Manufacture of white lead. June 3.

11,780, J. A. Maynard. Manufacture of oil paint in sheets. May 27.

12,085, J. J. Lee. Application of certain waste materials for the production of "mineral white," and process of making same. May 27.

15,903, N. K. Morris. Manufacture of carbonate of lead, and apparatus therefor. May 27.

16,684, J. S. Fairfax. — From F. Crane. Improvements in varnishes or coatings. June 10.

1891.

6916, T. Maxwell. Liquid preparation for protection of bright metallic surfaces, applicable as an anti-fouling and anti-corrosive composition. May 27.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

8796, B. Wright and D. Wright. Improvements in or relating to machinery or apparatus for staking, softening, and perching leather. May 23.

9064, J. Hundhausen. See Class XVI.

9624, W. Crowther and J. Crowther. Preserving a solution of tannin and keeping it from fermenting or changing into gallic acid. June 6.

COMPLETE SPECIFICATION ACCEPTED.

1891.

6852, F. Drew. Substitute for leather. May 27.

XV.—AGRICULTURE AND MANURES.

APPLICATIONS.

9348. C. Glaser. Improvements in and relating to a process for the treatment of phosphorites or other phosphatic materials. Complete Specification. June 2.

COMPLETE SPECIFICATION ACCEPTED.

1891.

5111. O. Jachne. Superphosphatic manure. May 27.

XVI.—SUGARS, STARCHES, GUMS, ETC.

APPLICATIONS.

8545. J. C. Mewburn.—From The Maschinenfabrik Grevenbroich, Germany. Improvements in the crystallisation of saccharine and other solutions. May 19.

8546. J. C. Mewburn.—From The Maschinenfabrik Grevenbroich, Germany. Improvements in the treatment of solutions which have been boiled to the granular state. May 19.

8893. A. Parks. See Class XVII.

9064. J. Hundhausen. Improvements in or connected with the manufacture of gluten and vegetable albuminous extracts. May 28.

9115. J. C. Firth. Improvements in cleaning Kauri gum. Complete Specification. May 29.

9168. E. Pechnik and S. Stein. Improvements in the manufacture of sugar. June 1.

9665. E. Ruescher. A process for separating impure sugar masses in one operation into crystallised sugar and molasses, avoiding all other products. Complete Specification. June 8.

COMPLETE SPECIFICATION ACCEPTED.

1890.

10,449. W. R. Hutton. Saccharate of lime. May 27.

XVII.—BREWING, WINES, SPIRITS, ETC.

APPLICATIONS.

8512. C. Funk. Improved method in fermenting mash, dough, wort, and the like. Complete Specification. May 19.

8518. J. Candwell. Improvements in the ingredients employed, and the method of their preparation, for the manufacture of brandy or cognac. May 19.

8893. A. Parks. Process of utilising the waste of distilleries, glucose, and starch works, &c. Complete Specification. May 26.

9004. R. H. Leaker and C. R. Bonne. Improved apparatus for drying brewers' grains and other materials. May 27.

9308. H. W. Joyce. Reek dissipator for improving malt kilns. June 2.

9763. W. P. Thompson.—From J. F. Theurer, United States. Improvements in the process of and apparatus for effecting the extraction of hops, with the simultaneous production of a fine extract. June 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

11,226. E. Craddock. Apparatus for treatment of grain for production of malt. May 27.

11,613. T. Reade. Preparation for fining or frothing beer and other fermented beverages. June 3.

11,672. C. O. Gridley and A. Bishop. Apparatus for the manufacture of finings and analogous materials. June 3.

16,942. F. T. Simson and J. Cox. Kola, or caffeine, or theine malt liquors, fermented wines and spirits. June 3.

1891.

7140. S. Mason, jun. Method and apparatus for purifying and refining alcoholic liquors and other fluids. June 3.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

8894. T. E. Brain. An improved process in the manufacture of artificial butter. May 26.

9239. L. E. McInliffe. Improved kinds of bread termed 'Rational breads,' and improved processes of preparing the same. June 1.

9790. V. H. Vincent. An improved process for the manufacture of oxygenated water, and apparatus therefor. June 9.

B.—Sanitary Chemistry.

9398. P. van Gelder. See Class II.

9482. W. E. Rowlands. Improvements in and connected with drying or desiccating animal matters. June 4.

9670. The Sewage Purification Co., Lim., and H. B. Jagger. Improvements in the means employed for carbonising refuse and other substances. June 8.

10,028. W. Ambler. Improvements in or applicable to apparatus for purifying smoke. June 12.

10,092. F. Livet. Improved apparatus for cremating house-dust and like refuse on new sanitary principles. June 13.

C.—Disinfectants.

8629. W. H. Spence. Improvements in apparatus for vaporising oils and other liquids for medicinal and disinfecting purposes. May 20.

8827. R. Armstrong. Improvements in the manufacture of detergent powder. May 25.

9083. C. Scott. Improvements in the method of vaporising carbolic and other disinfectants, and in apparatus therefor. May 29.

9491. T. H. Williams. The improved manufacture of disinfecting powder. June 4.

9492. T. H. Williams. The improved manufacture of disinfecting powder. June 4.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1890.

10,961. N. Etienne and A. Delhay. Preparing peptonised soluble meat and peptone. June 3.

20,640. W. Badenberg. Sterilising milk and other substances. June 17.

21,068. E. G. N. Salenius. Manufacture of butter, and apparatus therefor. June 3.

1891.

7335. W. P. Thompson.—From F. Lanhoff. Preparation or treatment of rice or other cereals. June 3.

7485. H. Warry. Food preservation. June 3.

B.—Sanitary Chemistry.

1890.

14,836, J. Lowe. Precipitating and filtering sewage. June 10.

XIX.—PAPER, PASTEROBOARD, Etc.

APPLICATIONS.

8857, E. Edwards. From J. H. Schnitz, Germany. An improved process of treating the leaves of the dwarf palm for use in the manufacture of paper. May 25.

8938, A. Johnston. Improvements in the manufacture of paper and in mechanism connected therewith. May 26.

9139, A. J. Boulton. From E. Rocca, Italy. Improvements in or relating to cellulose manufacture. May 29.

9852, J. L. Geddes, P. Culter, and J. W. Johnston. Improvements in and relating to the manufacture of parchment paper. June 10.

COMPLETE SPECIFICATION ACCEPTED.

1890.

7971, E. W. Crowther. Metallic foil coated air-tight and grease-proof paper. May 27.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

8541, P. A. Newton. From the American Endicott & Co., United States. Improvements in the manufacture of medical extracts. May 19.

8584, L. F. Riedel. Manufacture of an iodine derivative of phenacetin. May 19.

9024, W. Smith and W. Elmore. A new and more economical method for the production of nitrous oxide. May 27.

9131, H. H. Lake. From La Société Anonyme des Parfums Naturels de Cannes, France. See Class XII.

9439, H. H. Lake. From La Société Anonyme des Parfums Naturels de Cannes, France. An improved method of and apparatus for collecting the vapours of solvents. June 3.

9450, J. Y. Johnson. From F. von Heyden (Nachfolger), Germany. Improvements in the manufacture of iso-eugenol and poly-iso-eugenol. June 4.

9763, W. P. Thompson. From J. F. Theurer, United States. See Class XVII.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

10,432, K. Lütke, L. Scholvin, and L. F. Riedel. Manufacture of salicylate of phenylmethylpyrazoline. May 27.

11,802, L. Scholvin and L. F. Riedel. Manufacture of phenylmethylpyrazoline. June 3.

11,189, W. R. Lake. From Kalle & Co. Preparation of hydrochlorides, hydrobromides, and hydriodides of peptone. May 27.

11,196, G. D. Bowie. Phosphated salt:—"Sal. phosph." June 3.

12,993, J. Y. Johnson. From F. von Heyden. Manufacture of oxyphthalic acids (phenol dicarboxylic acids). June 10.

1891.

5981, J. Le Roy Webber. Manufacture of pepsine. June 17.

XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

APPLICATIONS.

8557, A. J. Boulton. From J. North, United States. Improvements in photography. Complete Specification. May 19.

8834, F. Sternberg. A process for producing photographs. May 25.

9984, J. Gray. A new permanent photographic printing process. June 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

9893, J. W. Swan and J. Leslie. Manufacture of transparent films for photographic and other purposes. June 3.

11,945, B. J. Edwards. Manufacture of flexible films for photographic and other purposes, and apparatus therefor. June 3.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

9196, J. B. Scarlett. Improvements in the manufacture of lucifer and other matches made of wood and cotton and other combustible or suitable material. June 1.

9485, T. Holmes. Safety-fuse igniting to be used in conducting blasting operations in mines, quarries, and the like. June 4.

9503, H. T. Ashton. Improvements in percussion fuses. June 4.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

11,720, R. J. Jones and G. Worrall (on behalf of Woodhouse and Rawson). Electrical fuses. June 10.

12,094, R. Morris. Electric fuse.

1891.

5843, A. Moschek and A. Brunner. Smokeless blasting compound and cartridges made therefrom. June 10.

7193, J. Y. Johnson. From J. A. C. de Latouche. Military and sporting ammunition. June 3.

THE JOURNAL OF THE Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 7.—VOL. X.]

JULY 31, 1891.

[Non-Members 30/- per annum; Members
21/- per Set of extra or back numbers;
Single Copies (Members only) 2/6.]

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond, F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.

COUNCIL FOR YEAR ENDING JULY, 1892.

President: Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.

Vice-Presidents:

Sir Lowthian Bell, Bart., F.R.S.	Ludwig Mond, F.R.S.
Wm. Crowder.	Dr. Hugo Müller, F.R.S.
James Duncan.	B. E. R. Newlands.
Dr. John Evans, F.R.S.	J. C. Stevenson, M.P.
David Howard.	A. Norman Tate.
S. H. Johnson.	Sir John Turney.

Ordinary Members of Council:

A. H. Allen.	E. K. Muspratt.
Arthur Boake.	T. L. Patterson.
Jno. Calderwood.	Boverton Redwood.
Dr. Charles Dreyfus.	Jno. Spiller.
H. Grimshaw.	T. W. Stuart.
Prof. R. Meldola, F.R.S.	William Thorp, B.Sc.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Dr. F. Hurter.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 3, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

A. H. Allen.	Prof. A. K. Huntington.
L. Archbutt.	F. Hurter, Ph.D.
G. H. Bailey, D.Sc., Ph.D.	Wm. Kellner, Ph.D.
Joseph Bernays, M.I.C.E.	Ludwig Mond, F.R.S.
H. Brunner.	T. W. B. Mumford.
E. Rider Cook.	B. E. R. Newlands.
W. Y. Dent.	John Pattinson.
Chas. Dreyfus, Ph.D.	W. H. Perkin, Ph.D., F.R.S.
John Heron.	Boverton Redwood.
D. B. Hewitt, M.D.	John Spiller.
David Howard.	A. Norman Tate.
Prof. J. J. Hummel.	Wm. Thorp.
	Thomas Tyrer.

Editor:

Watson Smith, University College, London, W.C.

Assisted by the following Staff of Abstractors:

S. B. Asher Aron. IV., IX., X.	T. A. Lawson, Ph.D. IV.
H. Auer. VII.	J. Walter Leather, } XV.
T. L. Bailey, Ph.D. Gen.Chem.	Ph.D. }

NOTICES.

Prints of the group photographed at Trinity College, Dublin, may be had on application to W. Lawrence, Photographer, 5—7, Upper Sackville Street, Dublin, price 5s. each.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SCOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January and May 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

LIST OF MEMBERS ELECTED, 8th JULY, 1891.

Cowley, A. J., 13, Fenchurch Avenue, London, E.C., analytical chemist.

Edwards, Thos., The Brewery House, Rhyimey, Mon., brewer.

James, Christopher, Swansea, metallurgist.

Johnson, Edmund E., Warren Hill House, Loughton, Essex, chemical student.

Kentrick, Prof. Edgar B., St. John's College, Winnipeg, Manitoba, public analyst.

Paseco, Edward, Vitriol Works, Ballybough Bridge, Dublin, works manager.

Prentice, Manning, Stowmarket, Suffolk, manufacturing chemist.

Quincke, Dr. Friedrich, 25, Alma Square, London, N.W., chemist.

Sims, Thos. P., 32, Windsor Terrace, Uplands, Swansea, analytical chemist.

Vredenburgh, Jas. B., Jersey City, N.J., U.S.A., counsellor-at-law.

LIST OF MEMBERS ELECTED, 23rd JULY, 1891.

Allan, F. H. Tielke, Portobello House, Wakefield, analytical chemist.

Black, Wm., 12, Romulus Terrace, Gateshead, analytical chemist.

Bott, Jos., Elton, Brimington Hall, Stockport, engineer and metallurgist.

Braithwaite, Isaac, Kendal, Westmoreland, dyer.

Coxe, Eckley B., Drifton, Luzerne Co., Pa., U.S.A., mining engineer.

Ellis, Alexander, Skelton, R.S.O., Yorkshire, pharmaceutical chemist.

Gregor, Jno. Bernal, c/o Jno. Lysaght, Lim., Bristol Spelter Works, Bristol, assayer.

Haslam, Dr. Arthur R., 64, Carysfort Avenue, Blackrock, co. Dublin, analytical chemist.

Jackson, Robt., 18, Harrington Street, Dublin, analytical chemist.

Kortright, F. L., 1,609, W. Genesee Street, Syracuse, N.Y., U.S.A., technical chemist.

Ludlow, Lionel, c/o Cape Copper Mining Co., O'okiep, Port Nolloth, South Africa, assayer.

McNeight, W. J., Eartwell, Palmerston Park, Dublin, dyer.

Moore, Wm. F., Lonsdale, Temple Road, Upper Rathmines, Dublin, dyer.

Palmer, Thos., 217, Temple Chambers, Temple Avenue, London, E.C., tanning chemist.

Preston, Alt., 131, Vicarage View, Bury, Lancashire, chemist.

Swinscoe, John A., c/o The Irish National Condensed Milk Co., Lim., Clonmel, Ireland, technical chemist.

Yoshimura, K., Awomoriken Chū-gakko, Japan, lecturer on chemistry.

CHANGES OF ADDRESS.

Angell, Jno., 1, o Ducie Grove; 6, Beaconsfield, Derby Road, Fallowfield, Manchester.

Brown, Jas. T., 1, o Chelsea; 28, Anhalt Road, Albert Bridge Road, Battersea, S.W.

Burn-Murdoch, J. V., 1, o Sevenoaks; c/o Capt. P. R. Burn-Murdoch, R.E., Shornmoor Fort, Gravesend.

Campbell, Colin M., 1, o Middlesbrough; c/o Jas. Laing & Co., 70, Wellington Street, Glasgow.

Chance, Alex. M., 1, o Westfield Road; Lawnside, Edgbaston, Birmingham.

Chas., W. H., 1, o Middleton; 24, Egerton Road, Fallowfield, Manchester.

Cornish, V., 1, o Manchester; George Hotel, Winchester.

Donald, S., 1, o Glasgow; Gasworks, Dundee.

Eastick, C. E., Journals to Myrtle Bank, Leyton, E.

Field, S. S., 1, o Eagle Villa; 1, Bell Rock Villas, Mycenae Road, Westcombe Park, S.E.

Field, Wm., Eddington, 1, o St. Kilda; Illawarra Road, Hawthorne, near Melbourne, Victoria.

Frankfeld, Dr. H., 1, o Manchester; 57, Rue du Général Foy, Ham, Somme, France.

Gordon, J. G., 1, o Landore; The Mannesmann Tube Co., Lim., 110, Cannon Street, London, E.C.

Hummel, Prof. J. J., Journals to 152, Woodsley Road, Leeds.

Huxley, J. H., 1, o Brincliffe Edge; 15, Kenwood Park Road, Sharrow, Sheffield.

Johnson, S. H., 1, o Forest Gate; Warren Hill House, Loughton, Essex.

Langenbeck, K., 1, o Cincinnati; c/o A. E. Tiling Co., Ed., Zanesville, Ohio, U.S.A.

Macallan, J., 1, o Clonliffe Road; 2, Marino Terrace, Clontarf, Dublin.

McEwen, Jas., 1/o Hulme; Ruthven House, Bowden Lane, Marple, Cheshire.

McKeehmie, D., 1/o St. Helens; Eccleston Grange, Prescot, Lancashire.

Mond, Alf. M., Journals to 20, Avenue Road, Regent's Park, N.W.

Neil, Jas., 1/o Glasgow; c/o Don Francisco de Miranda, Tumbes, Peru.

Neilson, Wm., 1/o Beekton Road; 7, Trinity Terrace, Hermit Road, Canning Town, E.

Pratt, J. W., 1/o Mobile; Belize, British Honduras, *via* New Orleans.

Pringle, Wm., 1/o Coorg; Laboratory, Bangalore, Southern India.

Rée, Dr. A., 1/o Middleton; 253, Wilmslow Road, Fallowfield, Manchester.

Smith, H. H., Plumstead, S.E.; retain Journals until further notice.

Steinhart, Dr. O. J., Journals to c/o May and Baker, Lim., Garden Wharf, Battersea, S.W.

Swinburne, G. Way, jun., 1/o Cumberland Gap; Harrogate, Claihorne Co., Tenn., U.S.A.

Typke, P. G. W., 1/o Fairlawn; Ravenhurst, Norbiton Park, New Malden, Surrey.

Warner, H. G., 1/o Wandsworth; c/o Croft, Wells, and Co., 1, Clive Row, Calcutta, India.

Weir, Surgeon-Major P. A., 1/o Ghazipur; Residency, Nepál, *via* Bombay, India.

Williams, Rupert G., 1/o Albany; Albion Mills, Heywood, near Manchester.

CHANGE OF ADDRESS REQUIRED.

Society of Public Analysts, 1/o 325, Kennington Road, London, S.E.

ERRATA IN LIST OF MEMBERS.

For "Corner, H.," read "Comer, H., P.O., Box 31, Jersey City, N.J., U.S.A."

For "Neiman, H. S.," read "Nieman, H. S., P.O., Box 35, Albany, N.Y., U.S.A."

For "Robey, C. M.," read "Tobey, C. H., Collingwood, Ontario, Canada."

PROCEEDINGS

OF THE

TENTH ANNUAL MEETING.

The Annual General Meeting of the Society was held on Wednesday, the 8th July, in the Examination Hall of Trinity College, Dublin.

The President, Mr. E. Rider Cook, took the chair at 11 o'clock. The proceedings were opened by—

The Rev. Dr. HAUGHTON, who said that he was instructed by the governing body of the University to appear there that day in conjunction with Dr. Emerson Reynolds, the Professor of Chemistry, to bid the Society a hearty welcome within the walls of Trinity College, Dublin. It was not on altogether unselfish grounds that they did so. They had reasons of their own for welcoming on its first appearance among them the largest society in existence connected directly with the promotion of chemical industries. He was aware that there was another chemical society, having more scientific objects, whose membership was larger; but he understood that this was the largest society in the world having for its object the promotion of such a large group of pursuits as must be embraced in the title of the chemical industries. They were rather backward in Ireland in that department of industry. It was not their own fault that they were so, and he dared not say that it was the fault of Providence; but whoever had given England, Scotland, and Wales, such a large quantity of coal had acted the part of an old step-mother to Ireland, to whom she had given none. He did not believe, and he hoped that the visitors would not believe, that Irishmen were naturally inferior to Englishmen, Scotchmen, or even to the men of gallant little Wales. He believed that if they only had coal, they would lead the van in chemical industry; but as they had not, they welcomed the Society, in the hope that by mutual contact between guests and hosts the visitors might take away pleasant impressions of Ireland, of its people and their ways, and in return communicate some stimulus to those chemical industries which were possible among them. He would say no more himself, but would ask Professor Reynolds, as the representative of the Irish School of Chemistry, to add some words on the objects of the meeting.

Professor J. EMERSON REYNOLDS, F.R.S., thought that he would best consult the pleasure of the meeting by saying very little. They were all "industrious chemists," and were anxious to get to business. But as Dr. Haughton had given him the opportunity, he wished on behalf of the professoriate of the University, as Dr. Haughton had already done on the part of the governing body, to give the members of the Society a hearty welcome to Dublin. It would be superfluous on his part to say anything about the objects of the Society, since they were well known to all present. All that they, the hosts, could do was to help the visitors to see Dublin and to enjoy their short stay there as thoroughly as possible. Antiquity had its disadvantages as well as its advantages; and in a 300 year old University some of the halls were not equipped as they would be in a modern college. They were, however, conscious of their disadvantages, and had taken whatever steps were possible for the comfort of their guests.

The PRESIDENT, in reply, said that he believed there would be an opportunity later on of formally expressing the gratitude of the visitors for the kind and hearty welcome they had received in Dublin. But he could not allow one moment to pass without saying on behalf of the Society that they accepted the hospitality which had been so generously offered with heartiness, because they knew that it was offered with the greatest possible sincerity. He re-echoed the hope expressed by Dr. Haughton, that while

they would undoubtedly be indebted to their Irish friends in the matter of hospitality, they might be able to repay that debt to some slight extent by awakening an interest in some of the manufactures of the country.

The GENERAL SECRETARY then read the Minutes of the last Annual General Meeting, held in Nottingham on the 9th July 1891; and these having been confirmed—

Professor C. R. C. THOMSON and Mr. C. C. H. JOHNSON were appointed scrutators of the ballot for the election of Council for the ensuing year.

The PRESIDENT then called upon the Secretary to read—

THE REPORT OF THE COUNCIL.

"We have the honour to report that the number of members on the register is 2,697, as compared with 2,595 at the last Annual Meeting. During the year 260 new members have been elected, and 158 have been removed by death, resignation, and other causes, showing a net gain of 102.

Among those who have died are Prof. T. Carnelley of the University of Aberdeen, Mr. C. H. Gillingham, at one time assistant to Mr. Crookes, and latterly manager of the Swan Light Works, Mr. J. Chambers Nicholson of the late firm of Simpson, Maule, and Nicholson, Mr. W. Lant Carpenter, an indefatigable member of Publication Committee; Mr. Chas. Marvin, the Russian traveller; Dr. M. Bechler of the Manbré Saccharine Co.; Mr. C. H. Grundtvig, killed by an accident in Greece; Mr. F. C. Blake of Pittsburgh; and Mr. Geo. Dyson of Hurworth-on-Tees.

During the past session 77 papers have appeared in the Journal, as against 87 the year before.

Ten years having now passed since the foundation of the Society, a few statistics are presented showing the progress of the Journal and membership during that period. In 1882 each number of the Journal averaged 43 pages of matter; in 1884, 56; in 1886, 61; in 1888, 79; and in 1890, 101. In 1882 the membership was 1,140; in 1884, 1,869; in 1886, 2,271; in 1888, 2,395; in 1890, 2,595. The invested funds of the Society amount to 3,880*l* 3*s*. 3*d*., as against 3,688*l* 15*s*. 9*d*. last year. The revenue last year, as will be seen from the Treasurer's report, exceeded the expenditure only by 107*l* 7*s*. 11*d*., as against 607*l*. in 1889, the increased size of the Journal being responsible for the whole outlay. If the rate of increase of the Journal is to be maintained, it is most desirable that we should have larger accessions of members.

In November last a Committee was appointed to consider certain proposals of the Manchester Chamber of Commerce to amend the Law of patents. Upon the report of that committee, the Council resolved to support the Chamber in endeavouring to limit the period during which inventors could retain their patents of rash and inconvenient claims, to two years after filing their original application. Should this alteration of the Law receive the sanction of Parliament, the speculative patentee will no longer hamper the chemical industries.

In May last a Yorkshire Section of the Society was formed with Sir James Kitson as its first Chairman. This makes the seventh, and the cordiality of your welcome induces a hope of the early formation of an eighth.

It will be remembered that we had intended to meet in Birmingham this year, but it became clear last autumn that the meeting could not be arranged. The Council, however, received a hearty invitation from a reception committee in Dublin, with the result that the Society is holding its Annual Meeting for 1891 within the walls of Trinity College.

The adoption of the report was moved by the PRESIDENT, seconded by Mr. HENRY BRIDGMAN, and carried unanimously.

The Hon. Treasurer (Mr. L. RICH. COOK) presented the accounts for the year, printed on page 599, and in doing so said that it would be unnecessary for him to do more than briefly state that the revenue for the year 1890 from all sources, exclusive of Life Composition Fees, amounted to 4,043*l*. Of this sum, annual subscriptions accounted for 3,053*l*.; interest, 133*l*.; advertisements, 536*l*., and sales of the Journal outside the membership, 294*l*.. The expenditure might be roughly stated to be, upon the Journal, 3,031*l*.;

Sectional expenses and Annual Meeting, 297*l*.; salary, 250*l*., and other small items, bringing the total expenses up to 3,908*l*. 5*s*. 11*d*., and leaving a balance of revenue over expenditure of 107*l* 7*s*. 11*d*.. The Treasurer's cash account showed that at the end of the year he had a balance in hand of about 370*l*.. In addition to this the sum of 3,880*l* 3*s*. 3*d*. had been invested in Metropolitan 3 per cent. Consolidated Stock, in the names of Mr. David Howard and himself.

The next item on the programme was the President's Address, but before proceeding to this the President said that he wished to draw attention to the fact that the annual meetings of the Society had hitherto been held in places where Local Sections of the Society had been formed. Dublin, however, without having a Local Section, had sent them a cordial invitation to hold the meeting there this year. He therefore wished his first words to be an expression of the sense of gratitude felt by the Society in accepting that invitation. He would also say that although Ireland did not possess a Section of the Society at present, he hoped that it would not be long before Irishmen would feel that it would be desirable to form an Irish Section, having its head-quarters in Dublin, and that the next invitation would come from the Chairman of that Section. Dr. Haughton had said that Ireland was behind England, Scotland, and Wales in manufacturing industries mainly because Providence had acted a sort of step-motherly part towards that country in not giving her coals. He thought that it was only due to the courtesy which one always expected from an Irish gentleman that Dr. Haughton had so limited the causes of Ireland's backwardness. Their Society was not a political one in any sense; at the same time in speaking of Ireland it was difficult to altogether avoid touching upon politics. But there was one thing upon which every Englishman who had read history, whatever his political opinions might be, was agreed, and that was that England as well as Providence had been a sort of step-mother to Ireland in respect of manufactures, and that there were acts of the English nation during the last century which had been deliberately planned in order to favour English industries at the expense of Irish. As he had said that every reading Englishman knew this, he would also say that every thinking Englishman regretted it, and was willing and anxious in every possible way to try to make amends for the wrongs which had been done to Ireland in those darker times. He hoped that the Society of Chemical Industry might be able in some small way to lend a hand to make up for the wrong done in those days. There was plenty of room in Ireland for the work of the Society of Chemical Industry. The main object of the Society was to teach manufacturers to do better what they were already doing. Substances and forces were altogether different from men. In social and political questions one had to deal with the imperfect individual atoms which went to make up societies, communities and nations. But in the case of substances and forces one had to deal with things which if they were properly used were certain in their operations. If one did right by them they would do right in return. Hence, chemistry came to the help of the manufacturer, not only in teaching him better methods of working than he was already pursuing, but in teaching him absolutely the right methods. The exact work of the analytical laboratory was brought to bear upon the rough work of the factory, and by degrees the results were brought nearer, not only to practical correctness, but to an absolute standard of perfection. Then the Society tried to teach manufacturers not only to improve on what they were already doing, but to do a great deal that they were not doing at all, especially in the utilisation of what had been called waste. There were many things in Ireland which were capable of being submitted to these two processes. Sir Robert Kane had shown that Ireland was rich in mineral wealth, and he could not believe that Nature had been so unkind to Ireland as not to supply her with the means of developing that wealth if the proper ways of doing so were found. The arrangements of Nature were generally perfect, and he had no doubt that if they only brought knowledge and care to bear upon the natural resources of Ireland, a great deal of its wealth might be developed. They had in Dublin an illustration in the great

* In addition to this there is an amount of £3,880 3s. 3d. Metropolitan & Consolidated Stock, invested in the names of Mr. David Howard and Mr. Edward Rider Cook.

We have compared the above Statement with the Receipt Book Counterfoils, Vouchers, and Books of the Society, and certify it to be correct. We have also verified the amount of the Metropolitan & Consolidated Stock, £3,880 3s. 3d., by reference to the Books of the Bank of England.

23, St. Swithin's Lane, London, E.C.,
19th February 1891.

(Signed) THEOBALD BROS. & MALL,
Chartered Accountants.

establishment of Messrs. Guinness of the very things which the Society of Chemical Industry was trying to teach manufacturers. They all knew that in the processes of brewing and distilling enormous quantities of carbonic acid gas were wasted. Messrs. Guinness had, however, been at work on the subject, and he believed that the members would have an opportunity of inspecting the machinery by which they were recovering from that waste product a large quantity—he was told something like 30 tons a day—of liquid carbonic acid. What would become of it he did not know; but past experience showed that a saving of this kind, which might be undertaken in the first instance with the idea only of effecting some small economy, generally formed the starting point of some great new industry. Ireland, moreover, and especially Dublin, was rich in the means for raising scientific chemists and men capable of superintending factories. They had in that magnificent institution under Professor Emerson Reynolds (President-elect of the Society) a school of chemistry quite equal to any school on the other side of St. George's Channel. They had in the Royal College of Science another admirable institution of the same kind. Dublin, therefore, could teach the men; and if the result of the meeting of the Society in Dublin should be that the capitalists of Ireland, or even some English capitalists, would put their capital and their plant under the superintendence of the men Dublin could produce in her scientific schools, then he believed that while they, the visitors, were debtors that day for the hospitality they had received, their hosts would be the first to acknowledge that they were indebted to the Society for having come there.

Mr. Rider Cook then proceeded to read

THE PRESIDENT'S ADDRESS.

In undertaking to give an address to the Annual Meeting of the Society of Chemical Industry, I feel sure I shall not be misunderstood in asking for your kind indulgence, following, as I do, so many distinguished men who have filled the Chair. Especially must I do so, because I cannot conceal from myself that I am indebted for the honour of the position which I now occupy to the fact that I have been able, since the formation of the Society, to render it some little service as its treasurer; whereas the distinction has usually been conferred on account of work done in the sphere of pure chemistry, or by reason of some great service to the commercial world in the region of applied chemistry.

It was only last year that Sir Lowthian Bell gave us a most interesting account of the result of his extended and laborious researches upon the chemistry of iron smelting, and in doing this, he was but following the custom of former Presidents, who have been able in their presidential addresses to give the results of original work. It has, doubtless, struck members of the Society that these presidential addresses have on several occasions dealt with the recovery and utilisation of waste products, and it might be expected, perhaps, that the first soap-maker who occupied this Chair would say something of the interesting recovery of glycerin from waste soap leys. But I am sorry to say that though my firm have benefited by the utilisation of this product which was formerly wasted, I am not able to give any information upon the subject which is not already well known.

It has occurred to me, however, that it might not be uninteresting or useless if, in the few remarks I shall venture to make, I take for my subject the utilisation of Sewage, a question in which, as a member of the late Metropolitan Board of Works, I took a great interest for many years, and which I think will sooner or later have to be dealt with by the chemical engineer, to whom, I am satisfied, we must look to save the country from the enormous loss which at the present time is incurred by the want of scientific treatment of, perhaps, the most important waste product of our time.

At the Jubilee dinner of the Chemical Society, Lord Salisbury, in his exceedingly interesting and lucid speech, said:—"I am an agriculturist under the guidance of Dr. Gilbert and others, and we compass sea and land in order to bring manure to make our products grow. What

is manure? Why it is an impure form of the carbon and nitrogen in which these products are bathed in circumambient air every day of their lives. I trust that the chemistry of the future will tell us why we have to go to Chili for these things and why we cannot take them from the air around us."

Now we all remember the interesting paper of Mr. Mond on the question of collecting the ammonia formed during the combustion of coal in furnaces, and I suppose the time will soon come when ammonia so obtained will be used for agricultural purposes.

We cannot tell what may be done in the future towards utilising the nitrogen of the atmosphere for the purpose of chemical manures, but it is a certain fact that if we can utilise the sewage of the country we shall be absolutely independent of Chili, and we ought to be able to save the 2,500,000*l.* per annum which we pay for imported phosphates and nitrates.

We ought, at any rate, to be able to save the expense of these fertilisers so far as they are used within the borders of our country, and are not exported, and also the cost of the sulphuric acid which enters so largely into the composition of artificial manures made from them.

I find the following figures in the Board of Trade returns, which show the money value of the imports of these articles for the last three years:—

		1888.		1889.		1890.
	Tons.	£	Tons.	Tons.	£	
Nitrate	381,894	..	1,102,583	..	903,632
Guano	159,179	..	160,191	..	138,001
Phosphates ..	258,000	544,919	305,000	703,704	343,500	849,452
Bones	66,000	310,983	63,000	310,263	70,000	372,048
		1,999,975		2,276,741		2,263,133
Acid (say)	321,000	..	368,000	..	413,500
		2,320,975		2,644,741		2,676,633

Of course a considerable quantity of chemical manure is exported, but, as native coprolites and also large quantities of animal matter of various kinds are used in the manufacture of chemical manures; and as the value of the manure exported includes these, as well as considerable sums for labour, expenses, and profits, it is difficult to know what deduction should be made from the above figures; but I think it may not be unfair to assume that the cost to this country for artificial manures, of foreign origin, used here is not less than from 2,000,000*l.* to 2,500,000*l.* per annum.

Now, it may be said that this subject is hardly appropriate to our Society. I venture, however, to think that this is a mistake; for while it is quite true that hitherto it has been considered a subject confined to the province of engineers, and especially of sanitary engineers, it is also true that *chemistry* has been repeatedly called in to mitigate as far as possible the injurious effects of sewer gas upon the atmosphere, and to prevent the water supplied to us from being rendered wholly poisonous, a result which is sure to occur so long as the circular system of drinking from rivers which receive sewage from towns is continued. Sometimes these efforts have not been altogether wise: e.g., in 1886, the Metropolitan Board of Works attempted to deodorise the sewage by pouring manganate of soda and sulphuric acid into the sewers. In 1886 the cost of this was 107,063*l.*, when only two grains of manganate to the gallon of sewage were used. It occurred to me that this expenditure was practically thrown away, and I therefore made some experiments from which I found that the average power possessed by a gallon of sewage in neutralising manganate of soda (20 per cent.) was as follows:—

In 1 minute	30 grains.
5 minutes	37 "
3 hours	67 "

that is to say, 287 tons of manganate would have been neutralised by 150 millions of gallons of sewage in one minute, while the quantity used by the Board was only 18·2 tons for that quantity. I not only reported these facts to the Board, but demonstrated them by experiments, with the result that the Board abandoned the idea of attempting to deodorise the sewage in the sewers, and in 1887 confined its operations to the effluent, after the sludge had been settled from it, and to sewage when it was actually being discharged into the Thames. The gain to the ratepayers was nearly 50,000*l.* in 1887, as the total cost of chemicals and labour that year was only 57,760*l.*, compared with 107,063*l.* in 1886.

I hope that even those who have doubts about the appropriateness of the subject will extend their indulgence to me, seeing that important as the pecuniary loss is to the country, the preservation of springs, streams, and rivers from pollution, and of our water supply from poisonous contamination, is of infinitely greater importance.

The magnitude of the evil resulting from the pollution of water sources is indicated by the fact that many of our large towns construct works to obtain their water supply from great distances, because the water upon which they naturally ought to rely has been polluted; *e.g.*, Glasgow from Loch Katrine, Liverpool from Lake Vyrnwy, Manchester from Thirlmere. It has even been proposed that London should get its supply from the Welsh mountains. The cost of these huge undertakings is enormous, and the result can hardly be considered satisfactory. In the event of war or domestic disturbance in the country the position of places thus supplied would be very critical. The destruction of a conduit as it passes, by a bridge, over a valley or, through a tunnel, under a hill would be most easy in these days of dynamite and gun-cotton, and the results to the population would be calamitous. And yet, as population continues to increase, unless the pollution of water sources is stopped, the number of large towns and cities which have to expend money in this way, and place themselves in this perilous position, will be constantly augmented.

I suppose there can be little doubt that, if properly utilised, the sewage of a country, together with the organic remains, such as the bones and the blood of animals which have been killed, should provide a fresh supply of food enough for the inhabitants of that country.

The food consumed by human beings and by animals may be said to be converted into—

- (1.) Their bodies.
- (2.) The substances associated with the air they give out from their lungs.
- (3.) Their excreta.

Their bodies sooner or later return to the soil, the gases exhaled are dissolved by the rain and dew and restored to the earth. Now if, instead of sending the excreta into the water, they were returned to the soil, the whole of the matter taken from it to form food would have been restored, and be available for the new crops of food for man and beast. Thus, speaking in general terms, the food of one year would have been so returned to the earth as to enable it to produce the food of another. So far, then, as we run this resultant of food away into the sea, in just so much do we impoverish the soil and do we waste the resources of our country by buying substitutes from foreign countries.

I do not suppose for one moment, as a writer to the "Times" stated some time since, that this is a loss to the earth as a whole; fortunately for us, nature is ever repairing our blunders, and without attempting to trace the process, I have no doubt that in sea-weed, and in sea-life, is stored up the wealth which we so lavishly squander—wealth which is recovered from time to time in a small degree by our own country but largely by other nations of the globe.

Some idea of the extent to which our production of food falls short of the amount annually required, may be formed from the following figures:—

Taking only the articles wheat and flour.

In 1888, wheat was imported amounting in value to 21,971,337*l.*, but we exported 156,070*l.* worth, leaving the

value for home consumption 21,815,267*l.*; in 1889 the home consumption was 22,387,050*l.*; and in 1890, 23,450,882*l.*, giving an average of 22½ millions of pounds.

In the same way, I find that the average value of flour imported for the last three years is 8,942,548*l.*, say 9,000,000*l.*, so that foreign wheat and flour consumed in England amount in value to 31,500,000*l.* annually.

Possibly some slight deduction should be made from this for exports of biscuits, cakes, and other manufactured articles, but on the other hand, a much larger sum must be added for foreign vegetables, potatoes, &c., and a large amount certainly for oats, maize, &c., which are consumed by animals, so that we may safely say that the imports of foreign food for man and beast cannot be less in value than 35,000,000*l.* per annum, but probably considerably more.

To this must be added the cost per annum of dealing with sewage—including cost of sewers, sewage works, and pumps, of efforts for the deodorisation and disinfection of this unutilised waste product, so that the loss to the country—

- (a.) By paying for foreign fertilisers;
- (b.) By buying food which we ought to grow; and
- (c.) By expenditure on works rendered necessary by the contamination of the water supplies which nature has placed close to our hands, but which we are compelled to abandon for more distant sources;

cannot be less than 10,000,000*l.* per annum.

Probably many may be disposed to say there is nothing new in all this, every one knows it. Unfortunately, however, the continuous crop of wild sewage schemes which are brought before the country shows us plainly that though the knowledge may be common, the practical results of it are by no means so. I want to ask those who think they know all about this important question, quietly to look at its present position, after the many years of failure, and after the destruction of so many hopes in connexion with it.

But we all know that the best means of attaining success is to learn the lessons which failure teaches, and I wish to point out one or two lessons which I think there can be little doubt, the experience of the last 20 or 25 years has taught. And first, in addition to the evils resulting from the pollution of our water supply owing to the water-carriage system of sewage, I think there can be little doubt that that system is responsible for a new and terrible evil by the production of sewer gas.

I know in raising any question in relation to the water-carriage system, I am running my head against a solid wall of popular prejudice, for certainly, as regards home comfort, that system has so many apparent advantages, that the great majority of people have settled down to it as if it were a finality.

A moment's consideration, however, will lead a thoughtful man to see that in attaining the comfort and cleanliness referred to, we have had to take associated with them some terrible evils. But for the system of water-carriage we should be ignorant of that subtle and insidious enemy sewer gas, which is no respecter of persons, and finds its victims in the houses of the wealthy, where bath-rooms and sanitary arrangements are most complete, quite as much as in the neglected dwellings of the poor; a gas which cannot be dealt with by any system of ventilation, but is liable to be ejected suddenly from the sewers by storm showers, or barometric changes, which we may meet with at any ventilator in the streets, and which may invade our homes at any time through a faulty pipe or a defective trap. In the sewers there exist all the conditions for the generation of this insidious and dangerous enemy, for the rise and fall of sewage has the effect of continually exposing organic matter upon an extended porous surface of brickwork to the influence of moisture and warmth in an atmosphere deficient in oxygen.

Secondly, the dilution of the sewage by water practically destroys its value as a fertiliser. There are many hills and moorlands in this country which contain thousands of pounds worth of silver and lead, but the cost of getting these metals is larger than the value of them when they have been obtained, and they remain unutilised, and for all intents and purposes worthless. And so with sewage; it contains matter which is of intrinsic value, but owing to dilution that

value is unavailable, as, in order to obtain a pound's worth of value, more than a sovereign has to be spent.

But, *thirdly*, the dilution in houses is followed necessarily by a further dilution in the sewers.

I know it has often been proposed that a system of double sewers might be arranged, one set for the purpose of sewage proper, the other set for the purpose of carrying away surface water.

Those who suggest this are ignorant of what all sewage engineers know, that when once sewage is turned into a sewer it is absolutely necessary to make use of the rainfall in order to flush the sewers and keep them in even a tolerable condition of wholesomeness.

The huge sewers in London, some of which are 11 and 12 ft. in diameter, have in some places, and for distances of several miles, a fall of only 1 ft. to the mile. The condition of these would be better imagined than described if they were not flushed by the rainfall.

The result of this second dilution is to render the volume of sewage simply appalling from its magnitude, and to reduce its actual value to a minimum.

The average daily flow of sewage dealt with by the Metropolitan Board was 150,000,000 gallons, and I suppose since 1888 that quantity has increased rather than decreased. This equals 670,000 tons per day. When settled and a comparatively clear effluent is run off, it leaves 3,000 tons of sludge, which when pressed in filter-presses can be reduced to 850 tons of cake of the following composition:—

	Per Cent.
Mineral matter.....	30.0
Organic matter.....	14.0
Water.....	56.0
Containing—	
Ammonium.....	0.001
Combined nitrogen.....	0.290
Phosphoric acid.....	0.750

An analysis of a gallon of the original sewage gives 3 grains of ammonia to a gallon, or 0.001 per cent.

Phosphoric acid, inappreciable.

(The above figures as to quantities were given me by the late Sir Joseph Bazalgette, the analyses by Mr. Dibdin.)

Now the ammonia is the only valuable constituent; and taking sulphate of ammonia, 25 per cent. ammonia, at 12/ 10s. per ton, a unit of ammonia in manure in a form suitable for putting on land is worth about 10s. per ton, so that the ammonia in a ton of London sewage is worth 0.001 of 10s., which is nearly $\frac{1}{d}$.

What can be done with a ton of sewage for $\frac{1}{d}$? It cannot be pumped, or settled, or pressed without expending far more than that sum, so that it may be said to be absolutely valueless, and the simple statement of this fact should convince speculators that by whatever process it is sought to recover this value, the working of such process must be ruinous in a pecuniary sense.

From this it will be seen that all hope of realising money value from the sewage, while the water-carriage system is continued, must be absolutely abandoned; that the country must be content to put up with the huge loss which it annually suffers; and that the question which local authorities have to decide is not how much they can obtain for what ought to be a valuable product, but how shall they get rid, at the lowest cost, to the ratepayers, of that which, by our folly in ignoring the laws of nature, we have converted into a nuisance.

It must be borne in mind, however, that this water-carriage system which is so disastrous seems to be, after the experience of the last 20 or 30 years, the very best that the engineer and the sanitary engineer can do for us. Are we then to be content to let matters rest as they are? May we not hope that the *chemical engineer*, who has already turned into value so many waste products, primarily for the good of the manufacturer, but necessarily also for the good of the country, will find some means of saving this enormous annual loss?

In the East, and in comparatively unimproved countries, the sewage, in ways more or less primitive, is placed on the soil, and even in overpopulated countries like China the result of this is that the soil produces food for the population

without imports. China is nearly as densely populated as England, as the following figures show:—The area of China, as given in the "Encyclopædia Britannica," is 1,399,609 square miles, population 370,323,545, or about 264 persons per square mile. Taking the area of the United Kingdom at 120,859 square miles, and population 37,075,000 (1887), it gives 306 persons per square mile, and yet, while Great Britain, as we have seen, imports vast quantities of food it is stated in the last edition of the "Encyclopædia Britannica" that "imports into China do not appear to include food stuffs."

In our own country, Mr. Moule by his earth-closet has achieved a certain amount of success, not by taking the sewage to the earth, but by bringing the earth to the sewage. But the cost of the carriage of the earth, and afterwards of the mixture, is of such importance that his system is not applicable to large towns or cities.

At Warrington, at Nottingham, and other places, I am informed a certain amount of success is obtained by the adoption of the "pail system," the manure being much appreciated by neighbouring farmers, and realising a substantial sum, in mitigation of the cost of collection. The want, however, of efficient deodorisation causes the system to have considerable drawbacks from a nuisance point of view.

Is it beyond hope that some chemical engineer will find not only the chemicals, but some efficient and convenient mode of applying them, by the use of which the refuse of each house may be quickly desiccated and deodorised, and remain so for a sufficiently long time to enable collection to be made from house to house, even in large towns, and the product conveyed to the country without any nuisance being occasioned, there to be restored to the soil by the farmers?

The requirements of a successful solution of the problem seem to me to be—

- (a.) The finding of a chemical or chemicals, the use of moderate quantities of which shall immediately deodorise excreta, and which shall arrest decomposition for some days.
- (b.) The construction of an apparatus, with or without the means of separating the solid from the liquid excreta, for the application of these chemicals, which while quickly removing the contents to a receptacle, shall be simple and cleanly in its action.
- (c.) The provision of a receptacle in each house which shall be readily accessible to the public authority, and which can be conveniently emptied.

Whether the problem will be solved or not remains to be seen, but the object I have in view will be answered if I succeed in convincing the members of our Society—

- (1.) That there is a great unsolved problem, involving the health as well as the wealth of the country, worthy of their attention.
- (2.) That no good will be done in the direction of sewage utilisation while the present water-carriage system continues; and
- (3.) That if public opinion will not admit of any interference with that system it is useless to devote time and trouble to any question other than how to get rid of sewage at the least cost to the community, and in doing so, how to avoid spoiling the water supplies of our ever-growing population.

Professor EMERSON REYNOLDS, in moving a vote of thanks to the President for his address, said that he wished the duty of doing so could have fallen into the hands of someone who was capable of discussing it in some detail. Under the circumstances, however, they must postpone a full consideration of it until they had the opportunity of seeing it in print; it being too full of information, and containing too many facts and figures of importance for its full significance to be realised at the moment. He thought that they might divide the President's remarks into two parts, it being essentially a double address. The first part he might venture to call the Dublin address, the second and larger part the general address, intended for the world in general, and which he was sure would be read with advantage in all parts of the world, but in Great Britain and Ireland in particular. He desired to thank the President for the very graceful allusions he had made to the very delicate subjects

connected with the relations of that country and the greater island on the other side of St George's Channel. He had skimmed delicately over very thin ice; and in a most interesting way had touched upon unpleasant episodes in the past, and brought into prominence the pleasanter possibilities of the present and the future. The President had said—though he (Professor Emerson Reynolds) had no intention of following him over that delicate ground—that he regretted the injustice of the past, and he had spoken kindly with reference to that injustice, which all who were acquainted with the history of the country would appreciate. But in mentioning the desire of their friends on the other side of the channel to help them now, he had forgotten one thing, he had omitted to mention that a return for a considerable portion of that debt of injustice to Ireland had already been made by his countrymen in giving their friends on the other side a very respectable amount of trouble. The President had referred to the utilisation of waste products in some of the manufactures which were of chief importance in that city. He referred to the great manufactures of the well-known liquid whisky and the equally well-known liquid porter. Those products were famous all the world over, and he believed that the members would have an opportunity of testing their properties in a full and interesting manner. They would also have at the great brewery of Messrs. Guinness an opportunity of seeing a most interesting novelty, the utilisation of the carbonic acid gas which was produced there in enormous quantities daily. It was, he thought, only a matter of common justice that the credit for that utilisation should be given in the right quarter. They had in Dublin, he was happy to say, a number of chemists of whom, perhaps, very little was heard, but who were nevertheless in the best and highest sense of the term industrial chemists; and he wished, therefore, to mention that the application of the utilisation of this important waste product, carbon dioxide, was mainly due to the efforts of a fellow-townsmen, Professor Tiehborne. It would be unreasonable to detain them with many observations respecting the second or general portion of the President's address. He had managed to treat a most unsavoury subject in a most interesting and valuable way, and had done great service to sanitary science by at once knocking on the head all the "promoters'" schemes of sewage utilisation proposed under the water-carriage system. He had clearly shown that the profitable utilisation of water-carried sewage was out of the question. If people were prepared to spend large sums of money for that purpose, sewage might be partially utilised; but the cost was so great as to render such schemes impracticable. Although the President's alternative proposals deserved and would receive much and careful consideration, he doubted whether it would be possible for the President, even with his great influence, to induce any public body to put aside the water-carriage system and go to the Chinese for examples of sewage treatment. He did not suppose that the President had really such an idea in his mind; but he had done a great service in showing so clearly that the profitable utilisation of sewage on the water-carriage system was almost out of the question. That system had many disadvantages, as they all knew; but the President had referred to one of them which his friend, the President of the College of Physicians, would appreciate, namely, the introduction of sewage gas into dwelling-houses. Efforts to prevent that danger had been many, and some of them had been partially successful, but none wholly so. Still he hoped that chemical engineers connected with that Society would turn their attention in that direction, and endeavour to remove that great source of danger to all communities in cities. Coming back to their own city once more, he might remind them that this question of the utilisation of sewage had been raised over and over again. They had often heard the expression "Dear and dirty Dublin;" they had had an opportunity of partially realising the meaning of that expression, and he feared that, if the elements should be unpropitious, they would realise it more fully later on, but he hoped not. One of their difficulties had been to deal with the surface cleansing of the streets and the disposal of the matter washed from them, combined of course with the primary difficulty of the treatment of the sewage. They

were placed, as his friend Dr. Haughton had put it, in a mud valley, down which their river swept and from which drainage was difficult. The methods which had been proposed for Dublin was to carry the sewage out to sea; but if they did that they would be introducing the elements of another "Irish grievance" by taking from their own shores valuable materials and, as the President had said, distributing them for the benefit of the world. That was a course which they decidedly objected to take. He would not detain the meeting longer, but would conclude by formally moving a vote of thanks to the President not only for his valuable address, but for the charming way in which he had placed his statements before them.

Mr. JOHN STILLER seconded the motion, and in doing so said that, as a colleague of their President from the time of the first formation of the Society, he desired to bear witness to the great value of his services. Whether in the capacity of treasurer (which position Mr. Rider Cook had held from the first) or in the special position of President which he had so ably filled during the past 12 months, he had always served the Society well. It was a pleasant duty to him therefore to second the motion so ably proposed by Professor Emerson Reynolds.

On the motion then being put by the Secretary, it was carried by acclamation.

The PRESIDENT said, in acknowledgment, that he was greatly obliged to the meeting for the vote which they had so kindly passed. He felt a happier man at that moment than he had felt at any time during the 12 months that had elapsed since he was elected President, for all that time the address had been hanging over his head. Feeling that he could not hope to bring forward anything that would compare with the addresses of previous Presidents, he had tried to find something to say which, if it did not give information, would at any rate do the next best thing—set his audience thinking. It was given to some to perform; to others to initiate, and if he had succeeded in starting somebody to work that day he would be amply rewarded for his trouble.

ELECTION OF AUDITORS.

Mr. S. H. JOHNSON moved that Messrs. Theobald Brothers and Miall be re-appointed auditors for the coming year at a remuneration of 10 guineas. The motion was seconded by Mr. Alfred E. Fletcher, and carried unanimously.

Mr. T. TYLER, as Chairman of the London Section, then invited the Society to hold its next Annual Meeting in London. London, he said, had already had some experience in entertaining the Society, and that experience, added to the invaluable lessons which it had learned from other local Sections, would, he hoped, enable it to keep up its reputation for hospitality. He had attended the meetings of the Society from the commencement, and had seen it received with uniform kindness and increasing hospitality. Each succeeding year had brought an aggregation of experience, and the novelty of one meeting served afterwards to make the next meeting a success. From what he had already seen, he was quite sure that Dublin would not be behind the other Sections in sustaining the reputation of the Society. He hoped that his Irish friends would come to London next year in as large a body as possible, so that the London Section might have an opportunity of repaying to some extent the generous and hearty hospitality of Dublin.

Mr. W. CROWDER seconded the motion, and in doing so re-echoed Mr. Tyler's hope that the next meeting might be an exceptionally large one.

The motion that the invitation of the London Section be accepted was then put by the President, and was carried unanimously.

The President then read the report of the scrutators, which showed that 239 voting papers had been sent in, and that the following gentlemen had been elected to fill the four vacancies among the ordinary members of Council:—Mr. Wm. Thorp, Mr. Boverton Redwood, Mr. Arthur Boake, and Dr. Charles Dreyfus.

The Council for 1891-92 is therefore composed as follows:—

President.

Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.

Vice-President.

Sir Lowthian Bell, Bart., F.R.S.	Ludwig Mond, F.R.S.
Wm. Crowder.	Dr. Hugo Muller, F.R.S.
James Duncan.	B. E. R. Newlands.
Dr. John Evans, F.R.S.	J. C. Stevenson, M.P.
David Howard.	A. Norman Tate.
S. H. Johnson.	Sir John Turney.

Ordinary Members of Council.

A. H. Allen.	E. K. Muspratt.
Arthur BAKER.	T. L. Patterson.
Jno. Calderwood.	Bowerton Redwood.
Dr. Charles Dreyfus.	Jno. Spiller.
H. Grimsshaw.	T. W. Stuart.
Prof. R. Meldala, F.R.S.	William Thorp, B.Sc.

Honorary Treasurer.

L. Rider Cook.

Hon. Foreign Secretary.

Dr. F. Hurter.

Professor EMERSON REYNOLDS said that he desired to return his hearty thanks for the honour which the members had done him in electing him President. His gratification was somewhat qualified by the fact that, according to his predecessor's experience, he must now turn his attention to the Presidential address for next year; he was glad, therefore, that so long a time had to elapse before presenting it. He should feel great pride in presiding over so important a body as the Society of Chemical Industry.

MR. B. E. R. NEWLANDS stated that under the Charter of the Imperial Institute the Society had the right of nominating a member of the governing body of that institution. He begged to propose that the outgoing President be appointed to that office. After the experience they had had of Mr. Cook that day, it needed no words on his part to press upon them the President's claims to their support in regard to this matter.

MR. T. W. B. MURDOCH had great pleasure in seconding the proposal. Everyone who, like himself, had had the pleasure of working with Mr. Cook knew how thoroughly suited he was for such a position. He was sure, therefore, that if they elected him he would prove to be a thoroughly worthy representative of the Society in the Council of the Imperial Institute.

The motion was carried unanimously.

The President thanked the members for the confidence they had placed in him. There was, he said, one more resolution to put which he was sure the members would not regard as a merely formal matter. He referred to a vote of thanks to the authorities of Trinity College for so kindly placing their rooms at the disposal of the Society on that occasion. He had already expressed the gratitude they felt to the Reception Committee, and he was sure that their gratitude to the College authorities was no less. It was interesting to him, and he was sure it was no less interesting to every other member that the meeting should be held in that historic building—the existence of which they had known ever since they knew anything at all, and the influence of which was not confined to Dublin or to Ireland, but was world-wide in its beneficence. He should look upon their meeting there as one of the red-letter days in the annals of the Society. He had therefore much pleasure in moving. That the heartiest thanks of the members be accorded to the authorities of Trinity College for their kind invitation to the Society to use their Hall and Council Chamber on this occasion.

MR. NORMAN TATE, in seconding the motion, said that he regarded the meeting in Dublin as a proof of the brotherly feeling that existed between the two countries. English chemists had come to Dublin to grasp in fellowship the hands of their fellow chemists in Ireland, and to unite in forming

one strong brotherhood to work in the great field of chemical industry which could do so much for the benefit of both nations. The Trinity College authorities had greatly assisted that object by granting the use of their beautiful building, and he had therefore great pleasure in seconding the motion so ably proposed by the President.

The motion was put, and was carried unanimously.

MR. W. G. STRYPE (Hon. Secretary of the Reception Committee) then made some announcements with respect to the arrangements for the excursions, &c., and this concluded the business of the meeting.

Several photographs of a large group of the members were then taken in the grounds of the College, after which at the invitation of the Reception Committee, a large party of the members partook of a substantial, and indeed sumptuous, luncheon in the "Antient Concert Room," Great Brunswick Street. In the unavoidable absence of the Lord Mayor, Sir Henry Cochrane, Deputy Lieutenant, presided, being supported by the President and Mrs. Rider Cook and Sir Charles Cameron, the City Analyst, on the right, and by Mr. Tyrer and Dr. Valentine Ball on the left. After justice had been done to the meal, the enjoyment of which was considerably enhanced by an artistic performance of Irish airs by Mr. John O'Donnell's orchestral band—

Mr. W. G. Strype gave some further information with respect to the excursions to be made that day in a humorous speech, which evoked frequent applause.

The President said that, notwithstanding Mr. Strype's efforts to prevent him, he did not intend to be deprived of the pleasure of proposing the health of the Reception Committee, coupled with the name of Sir Henry Cochrane, who had so kindly presided over the luncheon. He was sure that his friends would be disappointed if that toast were not given.

The toast was enthusiastically drunk with three times three, to which, at the invitation of Mr. Tyrer, hearty cheers were added for Mr. Strype, Mr. Boyd, and Mr. Wilson.

Sir Henry Cochrane briefly responded, and the company then separated to take part in—

THE EXCURSIONS.

A portion of the members proceeded by steamer, in charge of Dr. Haughton and Mr. Wesley Wilson, to inspect the Bay of Dublin, while others, to the number of about 70, under the guidance of Mr. S. P. Boyd, left Westland Row by special train for Dalkey, and thence proceeded by car to the Victoria Park, Killiney. Unfortunately, the weather was not propitious, as there was more than a suspicion of rain, with a dull leaden sky. Under these circumstances, the view, which includes the lovely Bay of Killiney, was not seen to its best advantage. The party then walked to Hlerton, Killiney, the seat of Mr. Samuel Boyd, J.P., who had most kindly invited the members to pass through his grounds. After examining the rare sub-tropical shrubs and ferns with which the gardens abound, among which were to be found palms and tree ferns rarely seen growing in the open air in this country, the visitors partook of tea and other refreshments, and returned to Dublin by the train from Killiney at 5.35.

THE CONVERSAZIONE.

In the evening the members attended a conversazione given, by permission of the Lords of the Committee of Council on Education, in the rooms of the Science and Art Museum, Kildare Street. A large number of ladies and gentlemen attended, and were received by the Lord Mayor and Lady Mayoress, Miss Meade, and Dr. Valentine Ball, the Director of the Science and Art Museum. Among those present were the President of the Society and Mrs. Cook, Professor J. Emerson Reynolds, the Rev. Dr. Haughton, Sir Robert Ball (the Astronomer Royal), Mr. Claude Guinness, Mr. Reginald Guinness, Professor Tichborne, Mr. Norman Tate, Mr. T. Tyrer, Mr. B. E. R. Newlands, Mr. John Spiller, Sir Nath. Staples, Bart., Dr. W. L. Dudley, Sir Chas. Cameron, and representatives of the rank and fashion of Dublin and the vicinity.

The Central Hall, the Rotunda, and the various rooms containing the art treasures of the Institution were brilliantly lighted by electricity; and the visitors, aided by programmes indicating the disposition of the various collections of relics, models, statuary, &c., &c., found no difficulty in passing a thoroughly pleasant evening. By the kind permission of Lieut.-Col. Courtenay and the officers, the band of the Royal Sussex Regiment was in attendance in the gallery of the central court, and gave an admirable performance of both instrumental and vocal music. The comfort of the guests was amply provided for in every way, seats and lounges being distributed throughout the building, and light refreshments being provided. The whole of the arrangements for the evening's entertainment were admirably carried out by Mr. W. G. Stryke and Mr. S. P. Boyd, the honorary secretaries of the Reception Committee, and by Mr. E. A. Werner, F.C.S. The company broke up about 11 o'clock, the general opinion being that the reception had been one of the most enjoyable that they had experienced in connection with the meetings of the Society.

SECOND DAY.

VISIT TO THE INCHICORE RAILWAY WORKS.

On Thursday morning a party visited the extensive workshops of the Great Southern and Western Railway at Inchicore.

These works have been in operation since the early part of 1846 previous to the line being opened for traffic on 4th August of that year. They have since been steadily increasing in size, until they now cover an area of 52 acres, upon which stand about eight acres of shop buildings. In 1847 the number of men employed was 259; there are now between 1,200 and 1,300. All the rolling-stock has for a considerable time been entirely constructed and repaired at these works; and in addition the various articles, such as lamps, barrows, &c., required for traffic and other purposes of the railway, are made and kept in repair. The rolling-stock consists of 178 engines, 530 passenger vehicles, and 3,820 waggons. In the boiler shop steel is used for the manufacture of locomotive boilers, and hydraulic riveting is employed as far as possible.

There are two erecting shops, one 286 ft. long and 50 ft. wide, with 16 pits; the other is 326 ft. long and 50 ft. wide, with 19 pits. The shops are provided with rope-driven gantries, and are divided by a traverser serving all roads in both shops; the traverser is driven by wire rope. On one side of the newest portion of the erecting shop, built in 1883, are the copper-smiths' shop and testing room; and at right angles to the erecting shops is the machine and fitting shop, about 324 ft. long by 50 wide.

By the courtesy of Mr. H. A. Ivatt, locomotive engineer of the Company, a splendid saloon carriage was placed at the service of the visitors, who at 10.30 left the Kingsbridge terminus, and shortly afterwards reached Inchicore. The party, on arriving at the works, were first conducted through the paint shop, where carriages, engines, and tenders were being painted. They next visited the trimming shop, where the carriages were upholstered. The foundry, which supplies all the iron and brass castings required in the shops, as well as castings for signal and other work for the permanent-way, was a very interesting section, and there locomotive cylinders were cast double, and axle-boxes, buffer-sockets, slide-valves, &c., were machine moulded. The locomotive smithy is 282 ft. long and 50 ft. wide, and contains 37 fires. Much of the work is done by stamping and welding under the steam hammer. Adjoining is the forge, which contains two Siemens gas furnaces and a 50-cwt. hammer. The boiler shop, the saw mill and joinery, the carriage and wagon, and other shops were all visited, and the inspection of the work carried on in them was regarded with the greatest interest. In one department a small bogie tank-engine, about 32 tons in weight, was lifted off the rails, and raised a height of 10 or 12 ft. This was done by a travelling crane. The lifting and moving of such an enormous weight afforded evidence of the power employed in those great workshops. The travelling crane was invented by Mr. Ramsbottom, on whom a few years

ago Trinity College conferred the honorary degree of Master of Engineering. Mr. Ramsbottom was succeeded at Crewe by another eminent engineer, Mr. Frank Webb, under whom Mr. Ivatt completed his education as an engineer, and qualified himself to become head of one of the greatest engineering establishments in the United Kingdom. Mr. Ivatt conducted the visitors to the erecting shops, and also showed them the fire engine department, which was a model of order and neatness. The Rev. Dr. Haughton observed with respect to it, "The perfection of a thing like this is to have everything right, though the misfortune of having to use it may never occur." The visitors were greatly pleased at having been afforded the opportunity of seeing the splendid and interesting work carried on in those great shops, and, after thanking Mr. Ivatt for his courtesy, returned to Kingsbridge in the saloon carriage in which they proceeded to Inchicore.

MESSRS. JOHN POWER AND SON.

Another party went to Messrs. John Power and Son's distillery in John's Lane, where they were received by Mr. J. Talbot Power, who, assisted by several members of the staff, conducted the visitors over the establishment. Unfortunately the "long vacation," common to distilleries in the summer months, had already commenced, but Mr. Power and his able coadjutors did their utmost to render the visit as instructive as possible by giving the fullest information on all points of interest. The first and most striking feature was the perfect cleanliness, brightness, and good order prevailing in every department, and at first sight almost conveying the impression that the various apparatus had not yet been put into practical operation. This was actually the case, we believe, as regards the first department entered, a handsome and roomy structure designed for use as a smithy, fitting, turning, and carpentering shops. Passing on, the corn stores, cleansing machines, new horizontal engines, and the malt kilns were severally inspected, and then the attention of the visitors was directed to the mill-room, in which were seen the huge stones and rollers employed for crushing and grinding the corn, and capable of so treating a quantity of grain equivalent to 1,500 barrels per day. Considerable interest was shown in the gearing for distributing engine power to the various pairs of stones and rollers, and the use of ropes in lieu of driving belts, every department being able to signal power on or off by means of electric bells. Crossing to another portion of the distillery, the party was conducted to a perforated iron floor above the brewhouse, from which they obtained a bird's-eye view of the two gigantic mash-tuns, each 33 ft. in diameter and 7½ ft. deep, and which, working alternately night and day, are capable of mashing 1,000 barrels per diem. Passing on, and noting *en route* the metal underbacks for receiving the wort from the mashing tuns, the powerful compound condensing steel beam engine, the 37 ft. steel boilers, the four coppers for boiling water and wort, and the system of refrigerators, the visitors arrived at the still-house, a building containing six of the largest pot stills in existence. From there an ascent was made to the gangway, from which a view could be obtained of three immense wrought-iron "worm tubs" fitted with copper coils of continuously diminishing section. From there the course lay through the sampling and filling rooms, and by means of a hydraulic lift worked by waste hot water from the worm tubs, to the bonded stores below. Passing again into daylight, and after admiring the small but beautifully fitted stables, the cooperage, the fire brigade shed, and last, but not least, the horses paraded with drivers and trolics, the visitors were received by Mr. Power in the counting house, where the finished product of the firm was submitted for approval. Here the President thanked Mr. Power for his kind and courteous reception of the members, and Mr. Power briefly replied.

MESSRS. GUINNESS, SON, AND CO., LIMITED.

The visit to Messrs. Guinness's great brewery was arranged and carried out in the most effective manner. On arriving at the establishment at St. James's Gate, the visitors were received by Mr. Claude Guinness. Each one

then received a tastefully bound description of the brewery, a card giving a general idea of the course to be followed during the visit, and a second card with a number corresponding to that borne by the guide of the party to which he was for the time attached. Some 10 or 12 gentlemen, each intimately acquainted with the establishment and its operations, acted as guides, and the visitors were apportioned among them in parties of from 10 to 15, the whole of the arrangements, however, being under the personal supervision of Mr. W. W. Wilson. Passing through the general offices into and across the space between the old and new breweries, the visitors were soon in a position to form a rough idea of the vast proportions of this historic concern. A map was supplied to enable one to grasp the general plan of the works, the tunnel connecting the higher with the lower portion of the premises, and the miniature trains rapidly conveying men and material from one part to another, all tending to produce the impression that one was passing through a busy town rather than the premises of a private firm. As affording some indication of the gigantic business of the Company, it was mentioned that the works cover an area of about 40 acres, afford constant employment to about 3,000 men and 150 horses, besides a great many more hired from outside contractors. The average brewing is about 3,000 barrels per day, and the Excise duty amounts to over 10,000, per month.

Passing through the engine room and malt-receiving room the visitors halted in the mill room and inspected the apparatus for taking out foreign matter from the malt and automatically feeding it in exactly proper weight to the respective mashing tuns, through crushing rollers. They then followed as far as possible the course of the malt and wort through the various processes, the next room visited being that devoted to a series of enormous mashing tuns. The brewery contains 16 of these, eight in each half of the establishment, capable of dealing with over 1,600 quarters of grain per day. Having watched for a time the operations of mashing and sparging, the party passed on to the coppers in which the wort is boiled with the proper complement of hops. Here it was incidentally mentioned that a larger proportion than usual of Californian hops are being used this season in consequence of the crop from that country being of exceptionally good quality. Leaving these huge coppers, each of which has a capacity of about 600 barrels, the visitors' course lay by way of the hop backs or cleansers to the refrigerating department, where the system of cooling the wort by Lawrence's patent refrigerators was much admired. Twelve sets of these were at work, the heated water being afterwards employed for washing returned casks. In this connection it was stated that about 1,000 hogsheds of boiling water are produced and used daily without the employment of fuel directly for that purpose. Passing then through the rooms in which the operations of fermenting and skimming were proceeding in various stages, the visitors inspected the processes of pressing and drying the yeast. In this department about 80 tons of dried yeast are produced per day, the whole of which is either sold to Irish distilleries or used in future operations in the brewery. Leaving this department and inspecting the gigantic fermenting tuns passed en route, the visitors arrived at what was for the majority of them the scene of the most interesting operation of the day, namely, the room in which is carried out the process of recovering and storing the waste carbonic acid referred to by several speakers at the Annual Meeting. It is impossible to predict to what proportions this industry may grow. The idea is quite new at present, and Messrs. Guinness's operations are therefore limited to producing sufficient carbonic acid to supply the requirements of their own establishment, and such demand as has already arisen in connection with the mineral water manufacture. The carbonic acid gas is collected from the fermenting tuns by means of parachutes from which it is drawn through pipes to this department, where, after passing through scrubbers to remove suspended impurities, it is liquified and stored in the ordinary steel cylinders. From here the party went to the freezing machines. The Company employs both the ether and the ammonia process of freezing, but only the former was in operation at the time, the object being to reduce a solution of calcium chloride to a low temperature, and pump

this through pipes traversing the various departments in which it is required. It is intended to replace the ether by liquid carbonic acid. After inspecting a few of the enormous oak vats in the storing department, of which there are about 150, some of them of 1,700 barrel capacity, the visitors passed from the new brewery by way of the stables to the malt stores. This is a gigantic building beside the canal, capable of storing a million bushels of malt. It is about 120 ft. high, and is divided into a series of bins, into which the malt, after being screened, is conveyed by hands worked by two engines of each 100 h.p., and consuming only 10 to 12 cwt. of coal per day. From the bins the malt is discharged as required into little railway waggons for conveyance by the railway mentioned above to the brewery. We were informed that the arrangements in this department are so admirably economical that two men can work about 1,500 qrs. of malt per day. Messrs. Guinness themselves produce about 4,200 qrs. of malt, and in addition take the production of eight commission houses. Some of the visitors proceeded by train to the maltings, a large and handsome building of five floors supported on innumerable iron columns, the three lower floors being devoted to malt and the two upper ones to barley. Others went to see the grain drying. Three machines are used— the Passburg, Millburn, and Hacking; each machine dries about one ton per 24 hours at a cost of 18s. 6d. per ton of dried grains. The product finds no market in this country, but is eagerly bought up for export to Germany. Thence a visit was made to the cooperage, the interesting operation of cleansing the casks by means of steam and hot air being inspected on the way. In the cooperage the visitors were much interested in watching the rapid manufacture, repairing, and numbering of barrels and hogsheds, every operation except that of drilling being performed by hand labour. Passing on through the saw mill, by the huge stores of timber and the forwarding department, the filling shed was arrived at, and here was seen in full swing the interesting and economical method by which the casks are rapidly filled to the bung-hole without the waste of a spoonful of liquor. It consists in employing an india-rubber tube for filling, a smaller pipe containing a glass tube being let into this near the bung-hole. The overflow passes back through this smaller pipe, and consists at first of air and "fog" or froth, and of black beer as soon as the cask is full. When this latter appears at the glass tube the supply pipe is transferred to another cask. It was stated that so expeditious is the operation that one man can fill 100 barrels per hour.

This completed the tour of the premises, and the visitors were next conducted to a room in which an excellent luncheon had been prepared for them. Here they were regaled with both solid and liquid refreshment, the renowned "double" and "treble" stout of the firm of course coming in for the lion's share of attention, but the mineral waters produced on the premises by the utilisation of recovered carbonic acid also received a considerable amount of favour. Congratulatory speeches having been made by the President and other leaders of the Society, and responded to by Mr. Guinness and Mr. Wilson, the members took their leave highly gratified with their visit.

MESSRS. JOHN JAMESON AND SON.

A few members availed themselves of the kind invitation of Mr. John Jameson to inspect his famous distillery. Arrived at Bow Street, they were gratified to find that working operations were going on, though, as the distilling season is practically over, only two stills were running. The party were conducted over the building by the Manager, and every facility was afforded for seeing every detail of the operations in this the most famous distillery in Ireland, or indeed in the world.

The tour of the premises completed, the visitors were invited to the offices, where samples of the famous "seven years old" were tested. The Manager apologised for the unavoidable absence of Mr. Jameson, who, he said, would have been delighted to have welcomed the members of the Society in person, and Mr. Newlands briefly returned thanks on the part of the visitors.

THE GARDEN PARTY.

A somewhat larger number on leaving Messrs. Guinness's attended the garden party in the Zoological Gardens, which were kindly placed at the disposal of the Reception Committee by the Royal Zoological Society. The attendance, though fashionable, was not so large as should have been attracted to a gathering of this kind. The visitors were received by the Committee, and at once proceeded on a tour of inspection of the gardens, under the excellent guidance of Dr. Valentine Ball, Secretary of the Royal Zoological Society. No better opportunity of inspection could have been selected, as the grounds are at present all that could be desired in regard to tidiness and order, and the pleasant change in the weather contributed to no small extent to the favourable appearance of the gardens. The band of the 1st Gloucester Regiment played a choice programme during the afternoon. Considerable interest was manifested in the various occupants of the cages—birds, beasts, and fish alike calling forth expressions of warm admiration. The guests were warm in their eulogies of the *carnivora*, especially those born and reared in the gardens. Refreshments were then served, and the members went away expressing themselves well pleased with their visit.

THE ANNUAL DINNER.

The Annual Dinner of the Society was celebrated on Thursday evening, 9th July, in the Town Hall, Kingstown, which had been tastefully decorated for the occasion by the proprietor of the Marine Hotel, in whose hands the arrangements for the banquet were placed. About 150 members and friends sat down. The President, Mr. E. Rider Cook, presided at the high table, being supported on the right by the Right Hon. the Lord Mayor of Dublin, Professor Fitzgerald, Sir Nathaniel Staples, Mr. Hugh Moore, Dr. Carte, Mr. J. Talbot Power, and Sir Charles Cameron, and on the left by Professor Emerson Reynolds, Sir Henry Cochrane, Dr. Finney, President of the Royal College of Physicians, Mr. H. Gray Croly, President of the Royal College of Surgeons, Mr. S. Boyd, Mr. J. McSheehy, and Mr. W. Anderson. The spur tables were presided over by Mr. T. Tyrer, Mr. S. H. Johnson, and Mr. Vereker.

Dinner having been partaken of:

The PRESIDENT proposed the first toast—"The Queen"—in a few felicitous words. This having been honoured with three times three—

The PRESIDENT proposed "The Reception Committee and Honorary Officers." This toast, he said, caused him considerable difficulty, not because there was nothing to be said in the way of commendation, but because there was so much to be said that he felt incapable of adequately performing the duty. As he had already stated, the Society was present in Dublin for the first time, not in the ordinary way by the invitation of one of its local Sections, but by the invitation of a Reception Committee consisting largely of gentlemen outside their own body, who had gathered themselves together for the purpose, had sent the invitation, and had backed up that invitation in a way which it was impossible to describe other than by saying that it was the best possible way in which it could have been done. He hoped therefore that this particular toast would be drunk, not in a formal manner, but with the Irish enthusiasm befitting such a toast on that hospitable Irish soil. He had had the opportunity during the day of talking to a great many members of the Society, and he had met with but one opinion, and that was that the hospitality which had been offered to them in the city of Dublin was almost unexampled. If they could put themselves in the position of one body instead of being a number of separate individuals, they might imagine themselves to be the German Emperor come over to visit the country, for they had certainly met with a right royal reception. Without wishing to make any comparison between the way they had been received there and at other places, all he could say was that if that was the way in which Irishmen were in the habit of receiving societies, he hoped that it would not be long before another invitation came, say from Cork, Belfast, or some other Irish city. With regard to the second part of the toast, the

Honorary Officers, he wished to point out that such perfect organisation as they had seen during the meeting was not attained by hazard or chance. It was the result of sheer hard work, and that hard work had been done by gentlemen who had given their time and labour voluntarily. Even hard work would not have been sufficient by itself; behind it there must have been hearty enthusiasm to have enabled them to carry out every detail of the arrangements in so perfect a manner. They had had perfect organisation and prodigious labour on the part of the honorary officers, and in addition—if he might judge of the members' feelings by his own—there had been an amount of personal geniality on every occasion which had made them feel that they were regarded as old friends. Personally, he could only hope that an opportunity would be afforded him next year of returning some of the kindness he had experienced from those gentlemen. He was sure that the whole of the visitors would join with him in upstanding to drink with all enthusiasm the toast he had the honour to propose, coupled with the names of the Right Hon. the Lord Mayor, Messrs. S. P. Boyd, W. G. Strype, and W. W. Wilson.

The toast having been enthusiastically drunk with musical honours—

The Rt. Hon. the LORD MAYOR said that he had much pleasure in thanking the members on the part of the Reception Committee for the very kind way in which the President had spoken of their puny efforts to entertain the Society. They had felt that they had very little indeed to show the members of such a Society, representing the vast chemical industries of England and Scotland. But they felt that there were some industries in their little city of Dublin which, although they could not strictly be called chemical, were nevertheless industries with which chemistry had a great deal to do, and which were regarded by Irishmen with considerable pride. The members of the Society had visited that day some establishments which Dublin was proud of. He referred firstly to Messrs. Guinness's brewery, and he was sure that those gentlemen who had visited that place must have been gratified by the way in which it was organised and carried on, and especially by the application of means for reducing labour and by the introduction of the latest discoveries in science connected with the industry there pursued. They had also seen the distillery of his friend Mr. Talbot Power, and he felt sure that those who had been through that establishment would admit that it was an example of an Irish manufactory, the machinery, appliances, and order of which was deserving of nothing but admiration. The members had probably seen larger works in England or Scotland, and he only pointed to these as instances of what could be done in a small country. He hoped, too, that the visitors had found some things to interest them in the city itself; at any rate, he thought they would admit that an attempt had been made to amuse them. On the part of the city of Dublin he could assure the Society of a hearty welcome on any future occasion.

Mr. S. P. BOYD said that he considered it one of the greatest privileges that had fallen to his lot to be permitted to take part in the work of the Reception Committee. The visitors had already seen some of the natural beauties of the place, and he hoped that they would see more on the morrow. But he wanted them to do something in return for the small amount of hospitality which it had been their privilege to extend to the Society. He wanted them to do their utmost to help Ireland through her greatest difficulty—the development of the natural resources of the country and the employment of the people. It might be the opinion in England that capital could not be safely invested in Ireland; but that opinion was not well-founded, and it was a matter which he hoped gentlemen who were largely interested in industries would take into consideration. Ireland was a splendid field for the development of industries. It possessed great natural resources, and all that was wanted was capital and enterprise to develop them. Irishmen were divided on many points, but they were united on one; they loved their native country. They believed that their country had a great future before it, and he hoped that gentlemen then present would assist

them in some measure in attaining that future. English capitalists were disposed to send their savings to Africa and other far-off districts instead of looking, as he thought they should do, nearer home; and of the fields for enterprise near home Ireland best deserved their attention.

Mr. W. G. STRYPE (who was unfortunately at times inaudible) thanked the President for the very kind way in which he had spoken of the work of the Reception Committee. That committee was not only mixed in character but large in number, consisting of about 120 members. Fortunately they had only one chairman, but then they had 15 vice-chairmen, two secretaries, and a treasurer. Mr. Strype then proceeded to give a most amusing description of the proceedings of the committee, showing how it had found itself unable to get on with business as a whole, with the 15 vice-chairmen all anxious to take the place of the chairman; how it had then divided itself into sub-committees, how the Paper Committee had thought it absolutely necessary to provide black-bordered paper and envelopes for the use of the visitors; how the Weather Committee had appointed the Rev. Dr. Haughton its chairman, as being the highest authority in Ireland on that subject, and the only man likely to have any influence with the Clerk of the Weather; how a little delay had occurred in making the preliminary arrangements, in consequence of which it was found that a rainfall of 10097 had been fixed for the day of the annual meeting; how the Clerk of the Weather insisted on having that amount of moisture down somehow; and how Dr. Haughton, by skilful diplomacy, had managed to make the rainfall occur at the time when the one excursion party was safe down in the cabin sampling the supplies of the Cigar Committee, and the other party was well under the protection of Mr. Boyd.

In the absence of Mr. W. W. Wilson, the treasurer of the Reception Committee, the President called upon Sir Charles Cameron to respond on his behalf.

Sir CHARLES CAMERON said that he need hardly explain to an audience of gentlemen, all of whom possessed more or less scientific knowledge, how necessary it was to the comfort and happiness of any one who had just eaten a good dinner accompanied by good wine, that the whole stream of nervous energy should be allowed to run steadily and uninterruptedly in the channels of digestion and absorption. He had been in that happy position that evening, until he was suddenly informed by his friend Mr. Strype, the autocrat of all their arrangements, that Mr. Wilson was unable to be present, and that he would have to take his place. That announcement had seriously interfered with the process of the conversion of peptones into parapetones which had been going on so nicely before; and he therefore appeared before them an imperfectly nourished man, utterly incapable of making such a speech as he would have made if his friend had not deferred to the last moment his decision not to come. Sir Charles then proceeded to discuss in a humorous manner the probable causes of Mr. Wilson's absence; and concluded by saying that while all the members of the Reception Committee had worked hard, none had done more or better work than their Honorary Treasurer, Mr. Wilson. He was sure that all the members would join with him in deeply regretting that their friend was not able to be present, and in thanking the President and the guests for the very kind way in which his name had been received.

The toast having been pledged with great enthusiasm—

Professor J. EMERSON REYNOLDS proposed "The Society." In doing so, he said that there had been so many humorous speeches that anyone who had to follow with a more serious set of observations was placed in a great difficulty, one of his disadvantages being that he must not even attempt to be amusing if he could; while he personally was on the other horn of the dilemma, that he could not be funny if he would. Sir Charles Cameron had provided him with one observation by describing the effects on his digestion of being called upon to address that great meeting within a few minutes. He would ask them, then, to endeavour to imagine the condition of any person who, like himself, had known for at least three hours that he was required to perform a similar function. The toast which

was entrusted to him was being given for the first time in that noble land of theirs; but he hoped it was not the last time it would be proposed. That toast was the continued prosperity of the Society of Chemical Industry. The history of that Society illustrated in a most exceptional way the truth of the old statement that "Unity is strength." He did not refer to that lower kind of unity—very real, nevertheless—which arose out of self-interest, but to that higher class of unity which was based on the desire of men to associate together for the promotion of the general welfare. Still he might refer to that form of unity of which he had spoken in the first instance, and which he had ventured to call a lower class of unity, as it really was from a theoretical standpoint. He might speak of that Society as including all the interests represented by that great chemical union which dealt with the enormous capital of eight millions that had been so freely subscribed in these countries. He might speak of that greater union represented by the Society, which was outside the alkali union and whose interests amounted to many times eight millions. He would perhaps not be exceeding his duty if he referred to that higher union still which existed in that Society between the men whose aim in life was simply to extend the bounds of human knowledge and those who sought to apply such knowledge for the benefit of the race. He would be unworthy even at a distance to follow in the footsteps of his excellent friend, the present President, if he did not recognise that the members of that Society required the stimulus which those who were engaged in the pursuit of pure science could give them in the development of the important industries with which they were connected; and that further they who were engaged in the pursuit of pure science received from those who applied their researches the most important stimuli to further exertions. This was a tempting theme on which to enlarge, but he dare not pursue it, as he was oppressed by the knowledge that an express train would shortly be in waiting for them. However, nothing could prevent that meeting, and especially the Irish portion of it, from wishing to the Society the highest and most prolonged prosperity, and an extension of its present membership of 2,700 to one many times that number. He therefore confidently asked the company to join him in drinking to the prosperity of the Society, and, if he might be permitted to add it, to the prosperity of those who had been concerned in developing its greatness.

The toast having been duly honoured—

The PRESIDENT said, in response, that he rose to discharge the duty of a moribund president in returning thanks for the kind way in which the toast had been proposed and received. A great deal had been said about digestion, and he would ask them to imagine his condition after abstaining from beer for ten years when he told them that he had been induced that day to imbibing some of Guinness's stout. What the ultimate result might be he knew not; but at present he was bound to confess that he found nothing seriously wrong. He thanked Dr. Reynolds heartily for the way in which he had proposed the toast. He did not intend to be modest on behalf of the Society, for he believed that it deserved all their good wishes. In returning thanks, he wished to explain that the Society was not the Chemical Society. That Society was intended for the advancement of the abstract science of chemistry, and great and glorious work had it done. The Society of Chemical Industry did not grant letters for people to use; that was done by the Institute of Chemistry, which body he hoped would soon be recognised throughout the length and breadth of the land as the Society which was to give weight and authority to scientific evidence given in courts of law. He did not believe in people putting S.C.I. after their names in order to get something out of it. The Society aimed at combining those who possessed a knowledge of abstract science with those who had the quite distinct power of applying scientific principles on a manufacturing scale. Therefore they wanted to number amongst their members not only chemists but manufacturers who applied chemistry to their manufactures. They did not want any test or qualification; all they required was that a man should recognise that chemistry was a great

help to the manufacturer. In the great contest that was going on between the nations of the world, those manufacturers who availed themselves of the principles of chemistry and physics would necessarily be the better able to hold their own against competitors. Just as by means of railways, telegraphs, and telephones countries were being brought closer and closer together and the markets of the world concentrated into one huge one, so they wanted to see the manufacturers of the United Kingdom in possession of every advantage that would enable them to hold their own in friendly if not in bitter competition with other nations. Therefore he asked everybody in Dublin and in Ireland whose interests were such that chemistry could help him, to join the Society, and he should be very much surprised if when they had read three copies of the Journal through they did not find that they had received five guineas' worth of value for their 25s.

Mr. W. G. STRYPE then made some announcements with respect to the excursions to take place on Friday, and—

The PRESIDENT stated that Mr. E. C. C. Stanford, whose name was down to propose the next toast, was compelled to remain in London to give some further evidence before a Committee of the House of Lords, and that his place would be taken by Mr. T. Tyrer, the Chairman of the London Section.

Mr. TYRER said that the duty which had devolved upon him was one which happily needed but few words. Had Mr. Stanford been present he would have been able to continue the humorous vein of which they had had several excellent examples. He, however, did not profess to be a past master in that art. Professor Emerson Reynolds had reminded them of the admirable manner in which the President had fulfilled his duties, and they had all had evidence that night of the hearty way in which he could perform the functions of his office; but the London members who had worked with him on the Council knew him better still, and those who like himself had known and worked with him ever since the foundation of the Society 10 years ago had found him always the same genial, hearty, thorough man of business which they had seen him that night. Speaking in the presence of those who knew every detail of his connexion with the Society, he could honestly say that that Society owed to no member, however able, diplomatic, energetic, or wise, more than it owed to that gentleman who would on the morrow cease to be its President. When in the early days of the Society he, Mr. Tyrer, became Secretary of the Metropolitan Section, he had found Mr. Rider Cook in the office of treasurer, and treasurer he had remained ever since; and those who knew the amount of work which such a position involved in a Society such as theirs, and the business capacity required to manage the finances so as to be able to produce yearly such a balance sheet as they had seen the day before, would appreciate the advantage that the Society had enjoyed in securing the services of such a treasurer. He could not pretend to speak of Mr. Rider Cook's services as eloquently as they deserved, but he did wish to emphasise the fact that those services were not altogether included in his year's work as President; they extended back for 10 years, and he hoped would extend forward for many years to come. Presidents might come and Presidents might go, like the river, but he was glad to say that as treasurer Mr. Rider Cook would remain with them, and he hoped that he would "go on for ever." He was quite sure that directed by such a treasurer the Society could not fail to "flow on" in the right direction. He therefore asked the company to drink in the most cordial manner the health of "The President."

The PRESIDENT, in responding, said that he had already taken up so much time that he would limit his reply to thanking them sincerely for the cordial way in which they had received Mr. Tyrer's kind words about himself. He wished, however, to avail himself of the opportunity to supply an omission which he had made in proposing the toast of "The Reception Committee and Honorary Officers." In addition to those gentlemen, the Society owed a deep debt of gratitude to the owners, and the representatives of the owners, of the works which they had visited. Amongst

those gentlemen were Mr. Geoghegan, who had so efficiently shown many of them round Messrs. Guinness's place; and Mr. Power, with respect to whom those who had had the pleasure of being conducted round the distillery by him felt that he not only had an interesting work to show, but that he showed it with a genuine courtesy such as could not be excelled. Those were the two places which he had visited himself, and with respect to which he was entitled to speak, but he had no doubt that those gentlemen who had visited the railway works and Messrs. Jameson's distillery had met with an equally kind reception. It would therefore be an omission on their part if they allowed that evening to go by without publicly stating how much they were indebted to those gentlemen for their kindness. He therefore begged them to accept his assurance that the members of the Society were sincerely grateful to them for the marvellous exhibitions of manufacturing industry and the development of machinery which they had had the pleasure of seeing in those works.

The toast having been cordially drunk—

Mr. H. S. JOHNSON, in proposing "Our Guests," admitted that he was somewhat uncertain as to whom the title referred to, seeing that, in the first place, the Society was in Dublin as the guests of the Reception Committee; secondly, the Reception Committee were there as the guests of the Society; and in the third place, a number of gentlemen were present as the guests of both the Society and the Reception Committee. The President had, however, saved him much trouble by his eloquent reference to those gentlemen who had received them so nobly and so well. But there were other gentlemen present who had not been alluded to. They had the honour of the presence of several gentlemen of the highest eminence representing certain learned societies: the President of the College of Surgeons, and other gentlemen of great distinction from other societies. Nor must they omit Mr. Samuel Boyd, who had received them with so much kindness and courtesy on the previous day. He would conclude by saying that after drinking the healths of the guests he had specially mentioned, he would propose that they should all drink each others healths in their respective capacities as the guests of each other. That, he thought, would be an admirable system to adopt when in Ireland.

Mr. HUGH MOORE, who responded in the absence of Mr. J. Talbot Power, briefly thanked the Society for the cordial manner in which the toast had been received.

Dr. H. GRAY CROLY, President of the Royal College of Surgeons, also responded on behalf of that body.

THIRD DAY.

On Friday the members divided themselves into three parties, and proceeded on excursions into the county of Wicklow. A special train left Harcourt Street station at 10.15 a.m., and conducted a large number to Bray and Rathdrum stations. Two sections of the party alighted at Bray. One proceeded on cars to Roundwood, *via* the Glen of the Downs, and the other to Enniskerry and Powerscourt. A party of about 60, under the superintendence of Messrs. W. G. Strype and S. P. Boyd, and accompanied by Mr. John L. Robinson, a well known archaeologist, drove from Rathdrum station to Glendalough and the Seven Churches. The "haunted holy ground" of Glendalough, the gloomy lake, and dark and broken hills, deeply impressed the visitors, who inspected the principal ruins of the district with the greatest interest. A larger party went to Enniskerry, Dargle, and Waterfall, in Powerscourt demesne, through which they were conducted by Professor Emerson Reynolds, President-elect of the Society. The dark, wooded glen of the Dargle and the thickly-wooded hills were viewed from the most favourable points. Powerscourt demesne and Waterfall, and the richly-clothed wood in the vicinity, was the attractive centre of the day. The party which selected Roundwood went by Hollybrook, driving through the beautiful grounds of Sir Richard Hodson and Kilmaecanogue, returning by Carrowhill and Rocky Valley. At Roundwood they were

conducted over the city waterworks by Sir Charles Cameron, Mr. Spencer Hart, C.E., and Mr. Andrews, assistant engineer. The entire party returned to town before 9 o'clock, highly pleased with the day's outing, and expressed to the Reception Committee the pleasure which their visit to Dublin afforded. Throughout the day the weather was very fine. This concluded the programme, and the members for the most part returned to England on Saturday morning.

During the meeting the Councils of the Chamber of Commerce and Royal Dublin Society placed their rooms at the disposal of members, and the Whisky Distillery Co., United Alkali Co., Messrs. Pim, Messrs. Johnson, Mooney, and O'Brien, Messrs. Thwaites & Co., Messrs. M. O'Brien & Co., Patent Pneumatic Tyre Cycle Co., Alliance Gas Co., Messrs. Cantrell and Cochrane, Messrs. J. Shanks & Co., and others opened their works for inspection.

London Section.

CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

Chairman: T. Tyrer.

Vice-Chairman: W. Crowder.

Committee:

D. Howard.	T. E. Thorpe.

Hon. Local Sec. and Treasurer:

W. B. Mumford, 1, Glendale Villas, Sylan Road, Wanstead, E.

Meeting held Monday, June 1st, 1891.

MR. THOMAS TYRER IN THE CHAIR.

GUM ARABIC AND ITS MODERN SUBSTITUTES.

BY DR. S. RIHDAL AND W. E. YOLLE.

SINCE the closing of the Soudan to commerce consumers have found increasing difficulty in obtaining supplies of gum arabic, and now only small quantities find their way to Europe from the Red Sea littoral and fetch almost prohibitive prices. Consequently the attention of users of mucilaginous and adhesive liquids has been drawn to other sources of natural gums, and an increased stimulus has been given to the manufacturers of dextrin and other gum substitutes. Some notes relating to the appearance and properties of these various natural and artificial substitutes for gum arabic may therefore be of interest.

The various natural substitutes may be divided into two great classes, those which are exudations from the different species of acacia, and those which are not.

Of the former class, the principal are the other African gums from Senegal and the Cape, and the different Australian wattle gums; whilst to the latter belong the Indian Ghatti gums.

The investigation of the commercial value of gums from various sources is naturally a problem of some difficulty, and some account of our experience in this direction, on the lines indicated by Liebermann and others, may be of service. Naturally the appearance and colour of the gums are of the first importance, and as they are generally bought and sold on an inspection of these physical qualities only, a brief description of the general characteristics of various classes of natural gum arabics is appended.

The finest gum arabic occurs in large white tears possessing a conchoidal fracture, even in size, and readily soluble in water, forming a viscid mucilage perfectly colourless and clear.

Samples of Aden gum arabic which nearly approaches the former in commercial value are in large white or yellowish white tears, mostly perfectly translucent and with the conchoidal fractures and fissures of genuine gum arabic. This gum generally contains a few fragments which are highly coloured and yields with water a viscid clear mucilage which is quite colourless and leaves no insoluble residue.

Cape gum occurs in irregular masses, not tear-shaped, and of an uniform brownish white colour. The fragments are smooth externally and not fissured. The gum is not so freely soluble as the true gum arabics, nor is the solution so viscid.

Indian gums other than Ghattis occur in irregular masses like Cape gum, but of a lighter colour, and contain many reddish lumps which, when broken, show an uniformly flat surface. It is freely soluble in water, but forms a weak solution and is not a good working gum.

Other samples of Oriental gums known in commerce as Eastern gum occur in tear-shaped masses of a whitish brown colour with conchoidal fracture. The gum is soluble in water, giving a fairly good mucilage.

Other African gums, of which the gum senegals are the most important, are found in fairly uniform fragments of a whitish brown colour and with a conchoidal fracture. They are soluble in water, forming a good mucilage.

All these gums are now met with in commerce and fetch varying prices.

These natural gums, as is well known, consist chiefly of arabic acid in combination with calcium, magnesium, and potassium, and a certain amount of moisture. A portion of the arabic acid, or arabin, may exist in the gum as metarabin, an insoluble modification of metarabin. Such gums leave an insoluble residue which swells up in water but does not dissolve.

As no process has been proposed for the accurate estimation of arabin directly, and as such a process, if available, could probably not give an index to the commercial quality of the gum, the analyst has to be guided by other considerations in the assay of gum.

From determinations of the ash of the sample, its viscosity in solution, which is a measure of its mucilaginous and adhesive power, and the amount of water which the natural gum contains, a fair idea of its commercial value may be ascertained.

The ash of a genuine natural gum should be white in colour and consist chiefly of a mixture of calcium, magnesium, and potassium carbonates, with a trace of sodium chloride.

The following table summarises the results obtained from typical samples from different localities:—

No. of Sample.	Ash.	NaCl.	K ₂ CO ₃	CaCO ₃	MgCO ₃	Total.
1. Aden.....	3.29	0.29	17.2	53.26	29.48	100.86
2. Cape.....	3.05	0.11	15.40	57.90	28.89	103.33
3. Indian....	2.03	0.57	12.6	58.50	29.82	101.29
4. Eastern...	2.08	0.24	26.8	43.50
5. ".....	3.19	0.21	18.01	44.70	34.30	97.22
6. Senegal...	3.03	0.14	21.5	54.90	15.96	92.59
7. ".....	2.11	0.11	24.9	53.10
8. Senegal...	3.38	0.11	17.14	50.32
9. ".....	3.18	2.00	13.65	59.39
10. ".....	3.66	0.21	15.8	54.50	39.07	100.58
11. ".....	2.76	0.24	17.10	49.04	29.94	96.32
12. Finest arabic	3.01	0.24	21.2	57.25
13. Good ..	3.15	2.30	20.9	46.23
14. Cape.....	2.61	2.20	12.2	52.73

It is commonly stated that gum arabic yields from 2 to 3 per cent. of ash, but we have not been able to find any record of analyses of the mineral constituents.

We tried most of the established tests used by pharmacists for the detection of gum arabic on all the gums which we have had an opportunity of examining. The aqueous solution of a natural gum invariably gives a white precipitate with alcohol, with ammonium oxalate solution, and with subacetate of lead. They do not appreciably reduce Fehling's solution when boiled with it, most samples being without any reaction; some however gave a slight reduction. Iodine in potassium iodide gave no reddish or blue colour. As dextrin and starch are almost invariably present in the artificial gums, this last reaction is of great value in the preliminary examination of a gum. Hager's reagent, which consists of a saturated solution of potassium ferrieyanide, with an equal volume of dialysed iron, and some dilute hydrochloric acid, was also tried; but its only value appears to be in discriminating dextrin from natural gums. With the former it strikes a deep blue colour on allowing the mixture to stand. The reaction of course depends upon the reducing power of the dextrin producing Turnbull's blue, no body having such a property being present in natural gums. The test is therefore of no use in discriminating between natural gums. Copper acetate and a few drops of acetic acid when boiled with the gum solutions gives no reduction, showing the absence of glucoses. Liebermann recommends the use of dilute potash and copper sulphate solution to effect the assay of gum arabic and gum senegal whether adulterated or not with dextrin. He adds first the alkali and then the copper sulphate solution to the cold aqueous solution of the gum under examination, filters off the flocculent blue precipitate of copper arabinatate after warming, and boils the filtrate, when dextrin, if present, causes a reduction of the copper sulphate. The precipitate on the filter is washed with warm water, dissolved in dilute hydrochloric acid and the free arabic acid (pure gum) precipitated by the addition of a large excess of alcohol. From the reaction of the gum acid thus obtained, he decided whether it has been derived from a true gum arabic or from gum senegal. It is evident that the distinguishing tests which he proposes depend for their success on the presence of accidental impurities, and not on any difference in the behaviour of the arabic acid, which is the chief constituent of both gums. The test which Liebermann most relies on is the formation of a colour on boiling with dilute potash. He remarks that gum arabics give an amber yellow colour, whilst senegal is scarcely affected. Our own experience does not bear out these results. We determined the potash absorptions of several samples of gum and also noticed the colour given by each:—

Gum.	Weight of KOH absorbed.	Colour produced.
1. Aden gum arabic	7.87	Yellow.
2. Cape gum	7.47	Yellow.
3. Indian gum	6.82	Green.
4. Eastern gum	9.04	Yellow.
5. Source unknown	5.18	Yellow.
6. African Senegal	2.48	Yellow.
7. Source unknown	2.39	Yellow.
8. Source unknown	6.16	Yellow.
11. Source unknown	2.08	Yellow.
12. Finest gum arabic	2.57	Green.
13. Good gum arabic	1.92	Green.
14. Cape gum	4.87	Yellowish brown.

From these results one would infer that the colour produced on boiling with potash is no indication of the source of a gum, as sample No. 1, a good gum arabic of ascertained purity, gives a yellow colour, whilst samples 12 and 13, also

genuine gum arabics, give a green colour when similarly treated. On the other hand, the majority of samples of gum from very different sources give a similar yellow colour on boiling with the KOH. It is possible that the tint produced is due to a slight decomposition of the arabin by the action of heat and potash. As will be noted further on, Ghatti gums from India react strikingly with potash, producing a characteristic pink colour. On the whole, so far as our experience goes, the methods of determining the source of any exudation from the acacia, chemically, are very unsatisfactory, and the chemist, like the gum consumer, has to rely chiefly upon the physical appearance and properties of the gum.

The determination of the moisture present in natural gums has established the fact that the loss on heating to 100° C. varies from about 10 per cent. to 15 per cent. of the total weight, but no attempt can be made apparently to classify gums according to the percentage of water they contain. Samples of gum of good quality lose more water often than inferior specimens, whilst the time of year in which the gum is collected has a considerable influence on the result. A marked difference is shown in the different losses of moisture undergone by dextrins and other artificial gums compared with natural gums. The dextrins at 100° C. appear not to lose more than 4 or 5 per cent., whilst no gum arabics which we have examined give such a low percentage. Liebermann states that the losses undergone by gums arabic and senegal respectively are 13.39 per cent. and 14.56 per cent. at 103° C. On the other hand, he found that the dried Senegal gum absorbed more water exposed to a warm damp atmosphere for 24 hours than the dry gum arabic, the respective increases being 6.15 per cent. and 2.24 per cent. It is of course obvious that the more water is expelled from a gum by heat, the more it will be prone to take up when re-exposed to moist air. All the samples of gum with which we have had to deal, have universally taken up more water when exposed upon glass slides over water in a bell jar. If the conditions are changed, however, they will lose this excess of moisture with a rapidity depending upon the nature of the gum. By experiments of this sort conducted in a specially constructed apparatus it is possible to obtain a fairly accurate idea of the behaviour of the gums used in envelope gumming, &c., when exposed to a tropical climate. This is a point of some practical importance, as it has been found that gums which work very well in the temperate zone are altogether useless when used for goods intended for India, &c., as in such climates a hygroscopic gum is valueless for stamps, envelopes, &c.

The determination of the viscosity of a gum solution is of great importance in forming an estimate of its commercial value. The usual method of doing this is to note the time taken by 50 cc. of a 10 per cent. solution to run out from a burette fitted with a fine jet, as compared with the time taken by water under the same conditions. The longer the time the more viscous the gum; but it is evident that the numbers obtained are not strictly proportional to the true viscosity, and at the best only relative numbers are obtainable. The qualitative results obtained in this way are of little value in fixing the true viscosity of any gum solution. The burette method informs the operator of the bare fact that one gum is better than another, but the results do not carry any quantitative significance, and he is left quite in the dark as to the extent of the superiority of the better gum. The figures obtained also vary so much with slight differences of temperature that very serious errors may arise if the operator, working on two different days, does not use for the purposes of comparison all the standard gums he had previously employed. A rapid and simple process for estimating viscosity which shall be free from the more serious errors of the burette method is evidently a desideratum, and we have found no difficulty in working with an apparatus which gives absolute results, and suggest that some uniform system might be adopted by those engaged in these determinations.

The adhesiveness of a gum is of course of great importance; and although we have made attempts to adapt the methods used for testing the strength of paper, glue,

belting, &c., for obtaining numerical values for this property, we find that a qualitative trial of the gum on paper gives practically all the information that is needed.

We found that with the above data a very fair estimate of the commercial value of a gum for any particular class of work may be formed.

The second class of natural gums now in the market are those of which Ghatti gum may be taken as a type. These gums apparently contain much more metarabin than the acacia gums, and consequently are not so readily nor so completely soluble in water. The fact that a considerable residue was left on treating the gums with water at first misled buyers, as the superior viscosity of the soluble portion was not immediately recognised. At the present time a considerable quantity of these gums are employed, partly as adulterants for the gums which are completely soluble in water, and partly by those manufacturers who find that the mucilages obtained from them answer their special purpose.

Ghatti gum generally appears in rough irregular fragments of a brownish colour and somewhat dirty, containing fragments of bark, straw, &c. It is much harder than gum arabic and not so brittle, so that it is a matter of some difficulty to reduce it to fine powder in a porcelain mortar. Most samples contain a considerable proportion of vermicelli-shaped tears of a yellowish white colour, which are almost insoluble in water and apparently consist of nearly pure metarabin.

The chemical examination of these gums is conducted on practically the same lines as for a gum arabic. The ash varies from 2 to 3 per cent. and consists of the same constituents as a gum arabic ash, viz., calcium, magnesium, and potassium carbonates, and sodium chloride, with the addition of alumina and a little calcium phosphate.

The loss of water on drying at 100° C. is not so high as for a gum arabic, being from 4 per cent. up to 7 per cent. The general hygrometric quality of this class of gums is good, and they are on the whole well suited for tropical work.

The viscosity of Ghatti samples, as compared with those of gum arabics is the most remarkable property of these gums. On first commencing work upon them, we found it necessary to employ a viscosity solution weaker than 10 per cent., as solutions of that strength would scarcely flow and were tedious to manipulate. We have therefore since employed universally 5 per cent. solutions in the determinations of their viscosity. A comparison of the figures obtained with them and with good gum arabics in the same burette shows the remarkable viscosity of the former:—

Sample.	Strength.	Burette time in seconds.
	Per Cent.	
1. Gum arabic	10	50
2. Gum arabic	10	70
1. Ghatti	10	117
Ditto	5	897
2. Ghatti	5	117
Ditto	10	117

Thus the Ghatti No. 1 is distinctly superior to gum arabic No. 1, which is the best Aden gum; whilst the other sample is considerably better than even Ghatti No. 1. As a matter of fact, none of the specimens of Ghatti gum which we have since examined have fallen below No. 1 in viscosity, so it is evident that this superior viscosity is one of the characteristics of this gum.

In two or three of the samples we have roughly estimated the amount of insoluble matter left on making the viscosity solutions, and have found it vary from 5 per cent. to 15 per cent. The gums are certainly markedly less soluble than the acacia gums, but the prolonged action of water appears to slowly dissolve the metarabin, probably by converting it first into arabin. The action of boiling water is much more efficacious, and far better solutions are obtained from gums

containing much metarabin by boiling the powdered gum with water. A cold water solution, however, has other advantages for some kinds of work.

Reference has already been made to the action of potash upon Ghatti gums. As a class they take up less potash per unit weight of gum than the gum arabics, although they differ considerably.

Sample.	Amount of KOH absorbed.	Colours of Liquid.
	Per Cent.	
1. Ghatti gum	3.79	Pink.
2. Ghatti gum	3.97	Pink.
3. Ghatti gum	0.23	Pink.
4. Ghatti gum	3.68	Pink.
5. Ghatti gum	0.225	Pink.

The pink colour of the solutions after boiling with KOH seems characteristic of the Ghatti gums, none of the others we have examined giving such a colour reaction.

Among the gums introduced into the market there are others which in physical appearance, &c. are markedly different to the rest. Among these the most important are the Amrad and wattle gums.

Amrad gum comes from the highlands of Abyssinia, and is an exudation from the *Acacia abaiet*. It occurs in commerce in dark brown or yellow tears with a smooth surface and fairly regular in size. It possesses a remarkable aromatic odour. The gum is soluble in water, leaving no residue, and giving a moderately viscid solution equal to the second class gum arabics. The ash is about 2.24 per cent., perfectly white and of similar composition to the ash of the other gums, being free from the alumina and phosphate which appear characteristic of the Ghatti gums. Its price is prohibitive at present of its superseding the second rate gum arabics and the Ghatti gums for commercial purposes.

A better prospect appears to be open for the Australian gums, which under the generic name of Wattle gum have been of late years introduced into the English market. All these gums which are classed together as wattle are exudations from numerous species of acacia. They are apparently divisible into two classes, the coast gums which contain much metarabin and swell up in water, and the gums from the interior which are freely soluble. In general appearance wattle somewhat resembles the commoner kinds of Cape gum, being usually of a dark brown or amber colour with a glassy even fracture, and dirty in appearance, owing to its being admixed with bark, &c. The higher grades are probably equal to the second class of gum arabics, but many samples do not attain this excellence. The ash is somewhat variable but usually lies between 2 and 4 per cent., not greatly exceeding the latter. The moisture is a trifle higher than for gum arabics, being 16 to 17 per cent. The gums yield a tolerably viscid mucilage which is said to be very adhesive. Unfortunately the best samples of this class of gum seem hard to get hold of, and are not apparently yielded in large quantities by the gum-bearing trees.

At present the gums are not exported in very large quantities, but there is certainly an opening for them if prices do not rule too high.

An exhaustive examination of the wattle gum-bearing trees and of the composition of the exuded gums has been made by J. Maiden, who divides them into three groups according to their solubilities in water, which, of course, depends upon the varying amounts of metarabin present (v. Maiden, Pharm. J. xx, 869, 980) [111].

Of the bodies which are artificially prepared and used as gum substitutes, the most important is dextrin. This has a widely extended use for cheap gumming work, and being easily "reduced," is in great favour. The commercial dextrins used for this work always contain more or less unaltered starch. They are therefore "reduced" with hot water or steam, and the starch thus gelatinised

materially affects the viscosity of the solution. Up to a certain limit, therefore, the presence of starch in a dextrin increases its commercial value for this class of work.

To distinguish between a dextrin and a natural gum is no difficult matter. Besides the iodine test there is the reducing action which commercial dextrins have upon Fehling's solution, and the absence of a precipitate with alcohol in dilute solutions.

Dextrins are readily distinguished from gums quantitatively by the low ash which they yield on incineration. Among the samples examined by us none exceeded .3 per cent. mineral matter, and some were much lower, just over .1 per cent. The ash appears to be of similar qualitative composition to that of natural gums, though alkaline carbonates are conspicuous by their absence; but the amount of chloride is considerably greater, and some samples contain phosphates and alumina.

The amount of water which dextrins yield on drying at 100° C. is smaller than for natural gums, but on raising the temperature to 110° C. they lose much more, as a general rule, as the following results show:—

Dextrin.	Loss Moisture at 100° C.	Loss at 110° C.
Sample 1.....	3.57	10.12
Sample 2.....	4.10	10.4

It is not advisable to subject gums to a temperature of 110° C. as they show a tendency to char and become slightly discoloured, so we have no reliable data as to the loss of water experienced by them at this temperature.

The viscosity of dextrins ordinarily is about equal to that of third rate gum arabics.

The behaviour of dextrins with potash is characteristic. They take up a large percentage of KOH and yield a deep red solution quite different to that given by gums arabic or Ghatti. Comparison with the previous figures will illustrate this:—

Sample.	Amount KOH taken up.	Colour of Solution.
	Per Cent.	
No. 1.....	25.4	Dark red.
No. 2.....	19.7	Almost black.

Both dextrin and gums give a precipitate on the addition of lead subacetate (Goulard). The filtrate is opalescent or milky with the gums, but is clear with a dextrin. This test has been recommended by Schloster for the detection of adulterants in gum, but while the iodine and Fehling tests are available, it seems somewhat superfluous and less easy of execution.

Of late years several varieties of dextrin made up somewhat to resemble gums have been put upon the market. To such belong Stead's patent dextrin, which is made by filtering ordinary dextrin solution through animal charcoal and evaporating with a little nitric acid, when a transparent mass is obtained, which is said to be free from any offensive taste. The adhesiveness is also said to be unimpaired by this treatment. A "starch" gum has also been prepared by an Alsatian firm by the action of sulphurous acid upon starch paste under pressure at a high temperature. The resulting liquid is evaporated in vacuo. This gum gives a blue colouration with iodine, showing presence of unaltered starch, and is used in confectionery. According to the patent specification the dextrin is free from odour and taste when the starch paste is boiled with half a per cent. of sulphurous acid until a trace of glucose can be detected. The resulting product is neutralised and filtered through animal charcoal, and then boiled down. The dextrin obtained is brilliantly white in colour. Schumann's non-fermentable cement is probably the same compound. This is made by mixing starch with water to a thin cream, adding acid and allowing to stand for 24 hours. The residual starch is washed free from acid and beaten in a digester to 160° C. or 170° C.

which converts all the starch into dextrin. The product is heated with a solution of albumen filtered through animal charcoal and evaporated to dryness. The resulting artificial gum is devoid of taste and smell and is similar in appearance to a natural gum.

Of a similar nature to dextrin and, from their consisting largely of it, almost identical with the former in chemical reactions, are the various artificial "gums." Numerous patents have been taken out for different methods of preparing these, but generally speaking they fall into three great classes, viz.:—

A.—Those containing only dextrin and gum.

B.—Those containing dextrin or other carbohydrates with nitrogenous bodies.

C.—Those consisting entirely of nitrogenous bodies, as liquid glue, fish glue, &c.

To the first class belong the patents of Rossi and Hellfrisch for preparing gum from starch by the action of sulphurous acid under pressure. The product consists of "gommaline," dextrin, and a trace of glucose, and is stated to be clear, non-hygroscopic, and to have an adhesive power nearly equal to gum arabic. This "gommaline," although a gummy matter, is not true gum. Little is known concerning it, but probably it is only a modified form of dextrin. If so the true place of this gum substitute would be under the real dextrins. An artificial gum was brought on the American market some two years ago, made by boiling down dextrin solution with gum arabic in vacuo. Several brands of "gum" made by this or a similar process are on the English market at the present time, and are used for many classes of work. Some consumers complain of them changing rapidly in consistency, especially in winter, and it has been recommended to boil the solid gums with $\frac{1}{2}$ times their weight of caustic lime, when it is stated the solutions retain their strength for weeks.

The general chemical characteristics of the first class of gum substitutes are low ash, indicating a high percentage of dextrin, loss of water on drying at 100° C., rather less than natural gum arabics, being about 10 per cent.; and moderate viscosity. None of the samples which have come under our notice have been above third rate gum arabics in this respect.

Among the second class of gum substitutes or mixtures of dextrin with nitrogenous compounds we may refer to the compound "arabol," which has been introduced into the market by an American firm. It contains dextrin admixed with some nitrogenous body, such as albumen or casein, and is put on the market as a brown sticky mass containing upwards of 35 per cent. moisture and yielding a light coloured solution which is not very viscid, about equal to that of a good dextrin. When boiled with aqueous KOH it assumes an almost black colour and absorbs 40.6 per cent. calculated on the dry material, pointing to a high percentage of dextrin as we have previously observed. The "Arabol" Company claim that the product works well both for envelope and label-gumming and lithographers' work, also for various general purposes as a substitute for gum arabic. It is open to the objection that it is very hygroscopic, although we are informed that this objection to its use has been remedied by an improved process of manufacture.

Gum substitutes of the second class will give low ashes on incineration unless, like Strasser's patent, borax or some other mineral preservative has been added. The ash of "arabol" we found to be 0.58 per cent. It was brown in colour and contained notable quantities of ferric oxide, alumina, and calcium phosphate associated with the usual constituents of a gum or dextrin ash, viz., calcium carbonate and sodium chloride, but no alkaline carbonates. This was the first body of this class in which we found ferric oxide in the ash. It also contains sulphate, which we had not previously found in dextrins or gums.

The viscosity of such substitutes must naturally vary very greatly, but none of those which have come under our notice were equal to second class gum arabics, even allowing for the higher percentage of moisture which they contained. It may be noticed, moreover, that they are easily affected by climate, more readily than dextrins as a class, so that it

would seem that the addition of gelatin, &c. makes the body more hygroscopic. On the other hand, when dry they exhibit a tendency to peel off the surface over which they are spread.

The third class of gum substitutes includes bodies which are made from animal matter.

To the first division belong the so-called "liquid gums" made by heating glue with water, borax, and carbonate of soda for some hours. When this is properly done the product remains permanently liquid on cooling, and may be boiled down to any required degree of strength. Other kinds of "liquid gum" are made by heating glue with alum.

The second division includes the gelatinous substances obtained from fish bones and cartilage, known under the name of fish glue. It is a light brown viscous liquid with an offensive odour and an acrid taste. It forms a sticky mucilage when diluted with water, and as met with in commerce already contains about half its weight of water, and such a liquid is, weight for weight, only about equal to a dextrin in viscosity. If the comparison were made on the dried fish glue, of course it would stand much higher, equalling some of the second class gum arabics.

The ash of these fish glues is comparatively high, being usually about 4 per cent. on the body dried at 100° C. It is usually white in colour and contains, besides calcium and potassium carbonates and soda chloride, some 5 to 10 per cent. of tricalcium phosphate.

On boiling with potash fish glue assumes a greenish yellow colour and absorbs a comparatively small amount.

Sample.	Ash.	CaCO ₃	MgCO ₃	K ₂ O	NaCl.	Ca ₃ P ₂ O ₈ + Al ₂ O ₃ + SiO ₂	Total.
	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.	Per Cent.
Amrad gum.....	2.24	67.20	16.62	7.39	0.14	4.86	96.21

Ghatti gum.....	2.24	60.90	10.33	9.29	0.30	30.80	101.62
Dextrin.....	0.12	6.45	15.10	73.40	94.68
Gum tragacanth...	2.803	76.30	8.89	11.90	1.14	4.71	101.97
Australan.....	2.09	20.80	0.45	3.21	1.91	65.95	92.32
Brazilian.....	1.39	11.80	0.45	17.74	0.468	68.14	89.6
Brazilian.....	2.38	15.50	10.10	17.12	0.213	53.50	96.78

The above are only intended to give a rough idea of the relative arrangement of the constituents in gums of known origin. They do not pretend to be strictly accurate, in fact the small quantities, never exceeding 0.2 gram, of ash operated upon forbid this. No provision was made for soluble silica, and the estimation of this in some of the gums would probably bring the totals nearer 100 per cent. The amount of potassium carbonate varies very much in the natural gums as reference to the table will show. Dextrins contain generally no potassium carbonate in their ash, while the gum substitutes of the first class increase in potassium carbonate according as more or less true gum is mixed with the dextrin. Amongst the members of the second group of gum substitutes we found no soluble alkali in "arabol," whilst fish glues are rich in potassium carbonate. It will be seen therefore that the presence of potassium carbonate in the ash of a gum or mucilaginous body generally denotes the presence of natural gum or gelatin, whilst its entire absence indicates the body to be largely composed of dextrin.

The potash absorptions which we have already alluded to were obtained with semi-normal aqueous potash and confirm those obtained by Rowland Williams, who used alcoholic potash. He found for three samples of gum arabic figures ranging between 5.5 and 9 per cent. of potash absorption, whilst a single sample of Senegal absorbed 10.42 per cent. It will be seen by comparing these figures by those obtained by us (page 611), that they fall fairly within the limits which we found with a much larger number of samples. The most marked discrepancy is in the gum,

A sample containing 45 per cent. of water gave a potash absorption of 9 per cent.

Liquid gums of this class are easily recognised by boiling with Fehling's solution, when they assume a violet colour and by the tannic acid reaction, the presence of nitrogen and the absence of the dextrin reaction with iodine solution discloses their identity.

The unpleasant odour and taste of fish glue is one of the objections to its use. Otherwise from a commercial point of view it is superior to many dextrins, but it is, like "arabol," somewhat weak in hygrometric character. It, however, rapidly becomes dry and crisp again.

We have made several attempts to remove the unpleasant odour from fish glue, and are still working in this direction. We have found that when the glue is heated on the water bath for several hours with borax, caustic soda, sodium carbonate, and lime, although they have a temporary deodorising effect do not permanently destroy its odour. A better method consists in boiling the fish glue with 1 per cent. sodium phosphate and adding 0.025 per cent. of saccharin. A fish glue thus treated loses its unpleasant odour almost entirely and also its acrid taste.

In reviewing the literature on the analysis and properties of natural gums, we were struck with the small amount of definite data arrived at from an examination of representative samples, and have thought that the following tabular statement showing the sort of results obtained from the analysis of the ashes of other gums than those given on p. 610, and the difference between them and artificial gums would be of interest:—

senegal, but if an Aden gum arabic, like our first sample, varies as much from another genuine gum arabic as do the values obtained for each, viz., 7.87 and 2.57, it is quite possible for two samples of Senegal gum to vary at least as much. The different colours produced by the action of potash on the various natural gums and on dextrin have already been noted.

If the ash falls below 1 per cent., and the potash absorption rises much over 10 per cent. the presence of dextrin in the sample may be regarded as certain. Ghatti gums, as was seen, give uniformly low results when boiled with potash, no sample absorbing as much as 1 per cent., while some are below 1 per cent. It is noteworthy, however, that when shaken with saturated baryta water and the resultant liquid precipitated with alcohol and filtered, and the amount of baryta left uncombined determined, Ghatti gums give a higher percentage of BaO absorbed than they should from the ratio K₂O : BaO. The following figures illustrate this, viz.:—

Ghatti Gum.	Amount KOH absorbed reckoned to K ₂ O.	Theoretical BaO absorption from ratio K ₂ O : BaO.	Actual BaO absorption.
Sample 1....	3.396	6.49	7.90
Sample 2....	3.680	5.99	7.36
Sample 3....	3.970	6.47	6.92
Sample 4....	0.230	0.371	0.40
Sample 5....	0.225	0.366	0.39

When alcoholic semi-normal potash is substituted for the aqueous potash both gum Ghatti and arabic give lower results, *e.g.* :—

Sample.	K ₂ O absorbed Aqueous.	K ₂ O absorbed Alcoholic.
Gum arabic.....	6.28	1.15
Ghatti gum.....	3.94	2.84

In both cases a gummy residue was left undissolved in the flask, whilst aqueous potash causes in every case an immediate solution of the gum on warming. It will be observed that the ratio of the alcoholic K₂O absorption to

require extending. The fact that the constituents of Ghatti are not nearly so insoluble in alcohol as those of gum arabic is also shown by the respective yield of precipitates with alcohol (page 621).

In order to compare gum tragacanth, which, although it has no adhesive value, makes a good mucilage, with the Ghattis we made a determination of the ash, potash absorption, &c., of a good sample of this gum. The detailed analysis of the ash is given on the preceding page. The potash absorption gave 12.6 per cent. K₂O absorbed or 15.94 per cent. KOH. The resulting liquid was bright yellow. Mr. R. Williams obtained, using alcoholic potash for two samples of tragacanth, the numbers 11.05 and 11.98 for the KOH absorption.

We have already pointed out that for the commercial valuation of the viscosity of gums the burette method is liable to give misleading results. It is true that the emptying times afford a measure of the viscosity of the gums, and were it possible or convenient to make up fresh solutions of various samples of gums, and take their viscosity by this method together with that of a newly received sample, the figures obtained would fix the place of the new gum with regard to any one of the old samples. But in practice it is certainly not convenient, nor even practicable, to make up viscosity solutions of 20 or 30 samples of gum, and we have found by experience that the numbers given by the burette method are useless by themselves, and give no indication of the value of the gum, for when it is necessary to determine the true ratio between the viscosity of various gums some other method must be employed. We have found convenient for this purpose a modified form of the apparatus described by Slotte. It consisted of a double bulb instrument, in which the two bulbs are connected by capillary tubing. The bulbs are practically of the same capacity, and one is fitted with tubes so that the solution undergoing trial can be sucked over, and afterwards when the first bulb is filled returned to the second by means of a tube for a second test. The capillary tube is continued upwards into the first bulb for half its diameter, so that no correction is required for the effect due to gravity upon the liquid in the second bulb.

The apparatus employed by us is shown in the accompanying diagram. The only essential difference is that it has only one bulb, the gum solution being sucked up from a bottle.

To take a viscosity determination by means of this apparatus, certain data must be known, as from them is calculated the "constant" k of the instrument.

This "constant" is equal to the value of $\frac{\pi r^4}{8 l q}$ where q is the volume of the bulb in cubic centimetres, l the length of the capillary tube in centimetres, and r the radius of the capillary in centimetres. The height h from the centre of the bulb to the extremity of the capillary is also required.

From the viscous nature of most 10 per cent. natural gum solutions, we generally use artificial pressure to raise the solution in the bulb, but it is quite possible theoretically to determine the viscosity of a gum by simply allowing it to flow out from the bulb and noting the time taken in seconds; and as this is the simplest case for the calculation of the result, we will consider it first. The gum solution is placed in the bottle, and the gum, by pressure or otherwise, is sucked up into the bulbs till the upper safety bulb is full. The solution is then allowed to run out from the bulbs back to the bottle under the influence of gravity alone, the time taken to flow from the upper to the lower mark between the bulbs being noted in seconds. Representing the absolute viscosity by η , we have :—

$$\eta = k g h d t$$

in which k is the constant for the instrument obtained as above, g the effect of gravity in C.G.S. units, d the density of the gum (average density of 15 solutions of 10 per cent. strength 1.024) and h the mean height previously taken. The value for η as thus obtained is usually a small decimal varying from 0.2 to 0.03 per cent., according as the sample is a good natural gum, or a dextrin or other gum substitute.

Diagram A.

APPARATUS USED FOR TAKING VISCOSITY OF GUMS.

the aqueous is much greater in the case of gum arabic than in that of Ghatti. This may furnish another means of identifying Ghatti gum, but our experiments on this point

If the value of the η of distilled water be taken previously to the viscosity, it will afford a check on the calculation on the h of the instrument as the absolute viscosity of water at various temperatures has been accurately determined by Poiseuille and others.

The method of allowing the gum to flow out by itself from the instrument is tedious with good samples of natural gum if 10 per cent. solutions be adhered to; but equally good results are obtained with much greater rapidity by sucking up and forcing out the gum under diminished pressure. The only disadvantage is a slightly more complicated calculation. When working under diminished pressure, the following expression

$$\eta = K \left(\frac{t_f + t_e}{2} H D + \frac{t_f - t_e}{2} h d \right)$$

gives the value of the viscosity where t_f is the time of filling, t_e the emptying time, and H the height of mercury pressure in centimetres, and D the density of mercury (13.6).

The equation in the above form is deduced from the general one—

$$\eta = K t \left(\frac{1}{2} d (V_1^2 + V_2^2) + (P - p) \right)$$

in which t is the mean time, and V_1, V_2 the velocities corresponding to the times t_f and t_e ; $(P - p)$ is the effect of difference of pressure expressed in dynes, and so is equivalent to $H D g$. Our working equation is obtained from the general one by neglecting $\frac{1}{2} d (V_1^2 + V_2^2)$, as this expression represents the kinetic energy left in the liquid after falling the height h , and thus, in cases where the time is large, is very small and may be disregarded. On the other hand, if the rate of flow be rapid, a correction first made by Slotte comes into play, which is a correction for the kinetic energy in the liquid which increases with the velocity, and in which allowance is made for the liquid at different portions not moving with the same velocity. The equation is expressed thus—

$$\eta = K \frac{t_f + t_e}{2} (P - p) + \left(\frac{d Q}{2 \pi r^3} \right) \frac{1}{\rho}$$

in which the first portion is a compressed form of the general equation above, whilst $\left(\frac{d Q}{2 \pi r^3} \right) \frac{1}{\rho}$ is the new correction.

It depends, as will be seen, on the size of the bulb and the length of the capillary, which remain constant, for the same instrument, and on the emptying time for the particular experiment. It will be seen, therefore, that as the emptying time increases so does this correction diminish, and, in fact, for times over three minutes may be disregarded. The best way of using this correction is to find once for all the value of $\left(\frac{d Q}{2 \pi r^3} \right)$ for the particular instrument in use, and call this K_2 . It is about 0.22 for an instrument of the dimensions described. Then Slotte's correction becomes $\frac{K_2}{\rho}$, and a table can be readily made of the values of the correction from 15 seconds up to about 150 seconds, which will be the highest emptying time ever likely to be obtained working with pressure. This correction is made on the uncorrected absolute viscosity which is previously worked out from the equation by and of logarithms and expressed as a decimal. The figures obtained thus can be transformed to a shape more suitable for practice by dividing the absolute viscosity of the gum solution by the absolute viscosity of water obtained in the same instrument at the same temperature and multiplied by 100, i.e., $\frac{\eta \text{ of gum} \times 100}{\eta \text{ of water}}$, Z , which is more convenient to use in comparing various solutions.

Subjoined is a table giving the absolute viscosity of various gums. A comparison of the uncorrected viscosities with the corrected shows the great importance of Slotte's correction for dextrans and inferior gum arabics, in other words, for solutions of low viscosity, whilst it will be observed to have little influence upon the uncorrected η obtained for the Ghatti gums and the best samples of gum arabic.

In the column for η corrected the differences due to the use of different instruments are of course eliminated. The absolute viscosity of water at 15° C. determined in four different instruments is shown below—

Instrument	1.	2.	3.	4.
η corrd. of water.	0.0109	0.01185	0.0124	0.0120
K value.....	0.000000898	0.000000863	0.000000832	0.000000852
K ₂ value.....	0.235	0.2175	0.226	0.204

Poiseuille's value for water being 0.0122.

The above values for various gums and dextrans were obtained at a constant temperature of 15° C. and are compared with water at that temperature. It is of the utmost importance that the temperature of the water surrounding the bulbs should be adjusted for each series of experiments to the temperature at which the absolute viscosity of the water was determined. As far as we have ascertained, in gum solutions there is a steady diminution in viscosity with increase of temperature until a certain temperature is reached, beyond which increase of heat does not markedly influence the viscosity, and it is possible that above this "critical point," as we may term it, the gum solutions once more begin to increase in viscosity. The temperature at which the viscosity becomes stationary varies somewhat with different gums, but broadly speaking it lies between 60° C. and 90° C.,

no gums showing any marked decrease in viscosity between 80° C. and 90° C.

The experiments we have made in this direction were conducted as follows. The 300 cc. bottle containing the gum was placed in a capacious beaker full of hot water, and the viscosity instrument was also surrounded with water at the same temperature. Thermometers were suspended both in the beaker and the outer jar. The viscosity at the highest temperature obtained, about 90° C., was then taken and repeated for every fall of 4° C. till the water reached the temperature of the air.

The values so obtained gradually diminished with the increase of temperature. From the η values obtained the Z values were calculated using water at 15° C. as a standard. From the Z values thus obtained taken as the ordinate, and the temperature of each experiment as the abscissa, curves were plotted out embodying the results, examples of which are given below. The curves yielded by three gums 2, 7, and 8 changed between 90° C. and 100° C., whilst gum sample 4 has a curve bending between 60° C. and 70° C. Experimentally this increase of viscosity of the latter gum above 60° C. was confirmed, but the critical point of the other solutions tried approaches too nearly to the boiling point of water for experiments to be conducted with accuracy, as the temperature of the bulbs diminishes sensibly while the experiment is being made.

If viscosity values have been determined it is possible to calculate the remaining or intermediate values for Z at any particular temperature from the general equation—

$$Zt = A + Bt + Ct^2$$

As an example of the mode of calculation we may quote the following. A gum gave the following values for Z at the temperatures stated.

Gum.....	50° C.	$Z_{50} = 228$
Gum.....	30° C.	$Z_{30} = 339$
Gum.....	20° C.	$Z_{20} = 412$

from which the constants—

$$A = 592.99 \quad B = -10.2153 \quad C = 0.0583$$

can be obtained and thus the value of Z_t for any required temperature. The numbers calculated for gums all point to a diminution in viscosity up to a certain point, and then a gradual increase. A comparison of some of the figures actually obtained in some of these experiments, compared with the calculated figures for the same temperature, shows their general agreement.

Curves showing viscosity change with temperature for three typical gums. A—Arabic VII. B—Senegal VIII. C—Ghatti 15.

EFFECT OF TEMPERATURE UPON VISCOSITY—GUM VII.

Temperature.	η	Z found.	Z calculated.
° C.			
50	0.0283	228	228.00
46	0.0305	216	240.55

38	0.0398	297	289.00
34	0.0410	330	313.08
30	0.0419	339	339.00
26	0.0445	339	367.80
22	0.0492	398	396.47
20	0.0511	412	412.00
18	0.0531	428	428.00

EFFECT OF TEMPERATURE UPON VISCOSITY.—GUM VIII.

Temperature.	η	Z found.	Z calculated.
° C.			
50	0.0430	347	347
46	0.0475	383	371.14
42	0.0502	405	397.69
38	0.0510	411	424.73
34	0.0575	463	454.06
30	0.0602	485	485
26	0.0637	513	517.82
22	0.0667	538	552.25
20	0.0707	570	570
18	0.0755	609	583.07

The constants for the first gum are those given in the preceding column, whilst for the latter they were—

$$A = 771.9 : B = -11.15 : C = 0.053.$$

As will be observed, the effect of heat appears to be the same upon the two typical gum arabics quoted above, an increase of temperature from 18° C. to 50° C. decreasing the viscosity by nearly one half in both cases, and the same seems to be true of most gum arabics. Roughly also the same holds good for Ghattis as the following numbers show:—

Gum.	Z at 18° C.	Z at 50° C.
Gum arabic.....	1016	579
Gum arabic.....	428	228
Gum arabic.....	609	317
Gum arabic.....	581	258
Ghatti.....	572	306
Ghatti.....	782	418

The following table shows the effect of heat upon the viscosity of a typical Ghatti:—

GHATTI GUM NO. 15.—VISCOSITY.

Temperature.	η	Z.
° C.		
50	0.0517	418
46	0.0581	468
42	0.0628	506
38	0.0726	585
34	0.0788	635
30	0.0857	691
26	0.0889	717
22	0.0919	741
20	0.0946	763
18	0.0964	777

There is therefore no essential difference in the behaviour of a Ghatti and a gum arabic on heating. Some interesting results, however, were obtained by heating gums, both Ghattis and arabics, at a fixed temperature for the same time, cooling, and then after making the solutions up to the original volume, taking their viscosities at the ordinary temperature. The effect of treating for two hours to 60° C., 80° C., or 100° C., a small permanent alteration in the

viscosity of the solution, and it would therefore seem desirable that gum solutions should be made up cold to get the maximum results. The following numbers illustrate this change, viz. :—

Gum Arabic 10 Per Cent.	Water 600	After heating to		
		69° F.	80° C.	100° C.
Z at 18° C.	55	168	170	517
Z at 50° C.	67	190	122	130
Z at 50° C.	17	287	258	394
Ghatti No. 188, 17.5 per cent. Z at 18° C.	1,193	780	620	778

The variation of viscosity with strength of solution was also studied with one or two typical gums. A 10 per cent. is invariably more than twice as viscous as a 5 per cent. solution. The following curve was obtained from one of the Ghattis. Similar results were shown by other gums.

Variation of Viscosity, with dilution. (Ghatti No. 888.)

It would seem, therefore, that strong solutions, say of 50 per cent. strength, would be more alike in viscosity than solutions of 5 per cent. strength of the same gums. In other words, the viscosity of a gum solution should be taken as nearly as possible to the strength it is used at, to obtain an exact quantitative idea of its gumming value.

The observation of this fact was one of the circumstances which decided us to use 5 per cent. solutions for the determination of Ghatti gum viscosities, the ratio between the 5 per cent. and 10 per cent. solutions of gum arabics being roughly the same as that between the respective weights required for gumming solutions of equal value.

From observation of the general nature of the solutions of Ghatti gums, and from the fact that when allowed to stand portions of the apparently insoluble matter passed into solution, the hypothesis suggested itself that metarabin was soluble in arabin although insoluble in cold water. If this hypothesis were correct it would explain the apparent anomaly of Ghattis giving solutions of higher viscosity than gum arabics although they leave insoluble matter behind. The increase in viscosity would be due to the thickening of the arabic acid by the metarabin. Moreover, the solutions yielded by various Ghattis leaving insoluble matter behind would be *all of the same kind*, viz. a saturated solution of metarabin in arabin more or less diluted by water. Still further, if the insoluble residue of a Ghatti be the residual metarabin over and above that required to saturate the arabin, then it will be possible to dissolve this by the addition of more arabin in the form of ordinary gum arabic. In order to see if this were the case the following experiments were performed. Equal parts of a Ghatti and of a gum arabic were ground up together and dissolved in water. The resulting solution was *clear*. It was diluted until of 10 per cent. strength and its viscosity then taken —

Contains 50 per Cent. Ghatti.			
A. Pressure 200 mm.	η	Z.	
Temperature 15° C.	0.517	2,569	

The viscosity of this solution therefore was considerably greater than the mean viscosity of the 10 per cent. solutions of the Ghatti and the gum arabic, viz., $\frac{0.288 + 0.0636}{2} = 0.1758$ for the calculated η . Hence it is evident that the increase in viscosity is due to the solution of the metarabin.

Next a solution was made from a mixture of 70 per cent. Ghatti and 30 per cent. gum arabic. This was also clear and gave a considerably higher viscosity than the previous solution.

Contains 70 per Cent. Ghatti.		
B. Pressure 200 mm.	η	Z.
Temperature 15° C.	0.3177	2,562

It will be obvious that the increase of viscosity over the previous solution in this case must be due to the smaller amount of the thin gum arabic which is present, i.e. in the first case there is more gum arabic than is required to dissolve the whole of the insoluble metarabin. Further experiments showed that this is also true of the second mixture, as the viscosities of the following mixtures illustrate :—

Strength of Solution.	η	Z.
C. 80 per cent. Ghatti.	0.3642	2,937
D. 75 per cent. Ghatti.	0.33095	2,669
E. 77.5 per cent. Ghatti.	0.4860	3,819

This last solution E, we called for convenience the "maximum viscosity" solution as we believe it to be a 10 per cent. solution containing arabin very nearly saturated with metarabin. As will be observed, its viscosity differs widely from those of solutions C. and D., between which it lies in percentage of Ghatti. The first-named solution C. contains *too little* of gum arabic to dissolve the whole of the metarabin, consequently there is a residue left undissolved, which of course diminishes its viscosity. The second solution D. is too low in viscosity, as it still contains too much of the weak gum arabic, and as will be seen further on a very slight change in the proportions increases or decreases the viscosity enormously.

We next tried a series of similar experiments with a Ghatti containing far less insoluble residue and which consequently would require less gum arabic to produce a perfect solution. Mixtures were made in the following proportions, viz. :—

13.3 per Cent. Ghatti.		
F. Pressure 200 mm.	η	Z.
Temperature 15° C.	0.0978	787
86.6 per Cent. Ghatti.		
G. Pressure 200 mm.	η	Z.
Temperature 15° C.	0.4336	3,197

This latter solution is approaching fairly closely to our "maximum viscosity" with the previous Ghatti, and probably a very slight decrease in the amount of gum arabic would bring about the required increase in viscosity.

When these experiments were first commenced we were still under the impression, which several months' experience of working with gums had produced, namely, that the Ghattis were quite distinct in their properties to ordinary gum arabics. But the new hypothesis, and the experiments undertaken to confirm it, showed clearly that if the viscosity of a gum solution depends on the ratio of metarabin to arabin, then there is no absolute line of demarcation between

a Ghatti and a gum arabic. In other words, there is a constant gradation between gum arabic and Ghattis, down to such gums as cherry gum, consisting wholly of metarabin and quite insoluble in water. Therefore those gum arabics which are low in viscosity consist of nearly pure arabin, while as the viscosity increases so does the amount of metarabin, until we come to Ghattis which contain more metarabin than their arabin can hold in solution, when their viscosity goes down again.

From these observations it would follow, that by taking a gum of less viscosity than the gum arabic previously used to dissolve the Ghatti, less of it would be required to do the same work. We confirmed this suggestion experimentally by taking another gum arabic of viscosity 0.5557 at 15° C. A mixture containing 93.3 per cent. of this Ghatti and 6.7 per cent. of our thinnest gum arabic, gave a clear solution which had the highest viscosity we have yet obtained for a 10 per cent. solution.

H. Pressure 200 mm.....	η	Z.
Temperature 15° C.	0.5525	4.456

This gum arabic may be regarded as nearly pure arabin (as calcium and potassium, &c. salt). By diluting the new "maximum viscosity" solution therefore with the 10 per cent. solution of the gum arabic in fixed proportions we obtain a series of viscosities which are shown in the following curve.

Curve showing influence of Ghatti upon viscosity.

Besides obtaining the curve for change in viscosity from maximum amount of metarabin to no metarabin at all, we also traced the decrease in viscosity of the "maximum" solution by dilution with water. The following numbers were thus obtained, and plotted out into a curve.

CHANGE OF VISCOSITY WITH DILUTION — "MAXIMUM"
SOLUTION. 15° C. TEMPERATURE.

Percentage.	η	Z.
10	0.55250	4.456
9	0.42850	3.456
8	0.35120	2.832
7	0.27660	2.230
6	0.22290	1.797
5	0.16810	1.355
4	0.11842	955
3	0.08023	647
2	0.06190	499
1	0.03610	291

Curve of variation in viscosity on dilution of the "Maximum" solution.

Having obtained this curve, we are now in a position to follow up the hypothesis by calculating the surplus amount of insoluble matter in a Ghatti. For, let it be conceded that the solution of any Ghatti leaving an insoluble residue is a mixture of arabin and metarabin in the same ratio as our "maximum" solution, only more diluted with water. Then from the found viscosity we obtain a point on the curve for dilution, which gives the percentage of dissolved matter. Now to show the use of this: The Z value for a 10 per cent. solution of the second Ghatti at 15° C. is 2.940. This corresponds on the curve to 8.4 dissolved matter. $10 - 8.4 = 1.6$ grms. in 10 grms., which is insoluble. We have already shown that a "maximum" viscosity solution of this gum is formed when 6.7 per cent. of thin gum arabic is added to it, and therefore 6.7 parts of a thin gum arabic are required to bring 16 parts of metarabin into solution. A convenient rule, therefore, in order to obtain complete solution of a Ghatti gum is to add half the weight in thin gum of the insoluble metarabin found from the viscosity determination. But the portion of the gum which dissolved is made up in a similar manner (being a diluted "maximum" solution).

Therefore the 84 per cent. of soluble matter contains 58 parts of metarabin, and the total metarabin in this gum is $58 + 16 = 74$ per cent. on the dry gum.

With these solutions of high viscosity some other work was done which may be of interest. The temperature curves of the mixtures marked E, G, and F were obtained between 60° C. and 15° C. The two former curves showed a direction practically parallel to that of the 10 per cent. solutions, and as they were approaching to the "maximum" solution, this is what one would expect. Mr. S. Skinner, of Cambridge, was also good enough to determine the electrical resistances of these solutions and the Ghattis and gum arabics employed in their preparation. The electrical resistance of these gum solutions steadily diminishes as the temperature increases, and the curve is similar to those obtained for rate of change with temperature. Although the curves run in, roughly, the same direction, there does not appear to be any exact ratio between the viscosities of two gums, say at 15° C. and their electric resistances at the same temperature; hence it would not seem possible to substitute a determination of the electrical resistance for the viscosity determination. The results appear to be greatly influenced by the amount of mineral matter present, gums with the greatest ash giving lower resistances.

Experiments were conducted with two Ghattis and two gum arabics, besides the mixtures marked E, F, and H. Comparison of the electrical resistances with the viscosities at 15° C. show the absence of any fixed ratio between them.

Gum or Mixture.	° C.	Ohms Resistance.	Z Viscosity at 15° C.
Ghatti, 1.....	10	5,467	1,190
Ghatti, 2.....	15	2,220	2,940
Arabic 1.....	15	1,350	605
Arabic 2.....	10	2,021	419
Mixture F.....	15	1,330	787
Mixture E.....	11.3	2,058	3,919

Whilst performing these experiments, an attempt was made to obtain an "ash-free" gum, in order to compare its viscosity with that of the same gum in its natural state. A gum low in ash was dissolved in water, and the solution poured on to a dialyser, and sufficient hydrochloric acid added to convert the salts into chlorides. When the dialysed gum solution ceased to contain any trace of chloride, it was made up to a 10 per cent. solution, and its viscosity determined under 100 mm. pressure, giving the following results at 15° C. —

	η	Z
Natural gum	0.05576	440
Ash-free gum	0.05431	438

Thus showing that the viscosity of pure arabin is almost identical with that of its salts in gum.

The yield of furfuraldehyde by the breaking down of arabin and metarabin was thought possibly to be of some value in differentiating the natural gums from one another, but we have not succeeded in obtaining results of much value. 0.2 gram. of a gum were heated with 100 cc. of 15 per cent. sulphuric acid for about 2½ hours in an Erlenmeyer flask with a reflux condenser. After this period of time, further treating did not increase the amount of furfuraldehyde produced. The acid liquid, which was generally yellow in colour, was then cooled and neutralised with strong caustic soda. The neutral or very faintly alkaline solution was then distilled almost to dryness, when practically the whole of the furfuraldehyde comes over. The colour produced by the gum distillate with aniline acetate can now be compared with that obtained from some standard substance treated similarly. The body we have taken as a standard is the distillate from the same weight of cane sugar. The tint obtained with the standard was then compared with that yielded by the gum distillate from which the respective ratios of furfuraldehyde are obtained. The following table shows some of these results. —

Substance	Comparative Yield of Furfuraldehyde.	Amount of Glucose Produced.
Cane sugar	1.00	—
Starch	0.50	—
Gum arabic	1.33	34.72
Gum arabic	1.20	45.65
Ghatti, 1	1.00	26.78
Ghatti, 2	1.33	22.86
Metarabic	1.75	—

The amount of reducing sugar calculated as glucose is also appended. This was estimated in the residue left in the flask after distillation by Fehling's solution in the usual way. The yields of furfuraldehyde would appear to have no definite relation to the other chemical data about a gum, such as the potash and baryta absorptions or the sugar produced on inversion.

The action of gum solutions upon polarised light is interesting, especially in view of the fact that arabin is itself strongly laevo-rotatory ($\alpha_D = -39^\circ$), whilst certain gums are distinctly dextro-rotatory. Hence it is evident that some other body besides arabin is present in the gum. We have determined the rotatory power of a number of gum solutions, the results of which are tabulated. On first commencing the experiments we experienced great difficulty from the nature of the solutions. Most of them are strictly yellow in colour and almost opaque to light even in dilute solutions such as 5 per cent. We found it necessary first to bleach the gums by a special process. 5 grams of gum are dissolved in about 40 cc. of lukewarm water, then a drop of potassium permanganate is added, and the solution

is heated on a water-bath with constant stirring until the permanganate is decomposed and the solution becomes brown. A drop of sodium hydrogen sulphite is now added to destroy excess of the permanganate. At the same time the solution becomes perfectly colourless.

It can now be cooled down and made up to 100 cc., yielding a 5 per cent. solution of which the rotatory power can be taken with ease. Using a 200-mm. tube and white light the above numbers were obtained.

Gum or Dextrin.	Solution used.	$[\alpha]_D$.

Ghatti, 1	5	- 39.2
Ghatti, 2	5	- 80.4

These numbers do not show any marked connexion between the viscosity, &c. of a gum and its specific rotatory power.

When gum arabic solution is treated with alcohol the gum is precipitated entirely if a large excess of spirit be used. With a view to seeing if the precipitate yielded by the partial precipitation of a gum solution was identical in properties to the original gum, we examined several such precipitates from various gums to ascertain their rotatory power. We found in each case that the specific rotatory power of the alcohol precipitate redissolved in water was not the same as that of the original gum. In other words these gums contained at least two bodies of different rotatory powers, of which one is more soluble in alcohol than the other. O'Sullivan obtained similar results with pure arabin. The experiments were conducted in the following manner:—

(a.) Five gums, of a dextro-rotatory gum (No. 3 in table) were dissolved in 20 cc. of water. To the solution was added 90 cc. of 95 per cent. alcohol. The white precipitate which formed was thrown on to a tared filter and washed with 30 cc. more alcohol. The total filtrate therefore was 140 cc. The precipitate was dried and weighed, 2.791 grms. or 55.88 per cent. of the total gum. The precipitate was then re-dissolved in water, bleached as before and diluted to a 5 per cent. solution. This was then examined in the polarimeter. Readings gave the value $\alpha_D = +58.4$. The previous rotatory power of the gum was +66. Now the alcohol was driven off from the filtrate which, allowing for the 11.95 per cent. of water in the gum, should contain 32.17 per cent. of gum. The alcohol-free liquid was then diluted to a known volume (for 5 per cent. solution), and α_D found to be +57.7. This experiment was then repeated again, using 5 grms. of No. 3, when 3.5805 grms. of precipitate were obtained, using the same volumes of alcohol and water. The precipitate gave $\alpha_D = +57.4$; the filtrate treated as before,

only the percentage of gum dissolved being directly determined instead of being calculated by difference, gave $[a]_D = +52.5$.

(b.) Another gum (No. 9) with $[a]_D = -38.2$ and containing 13.86 per cent. of moisture, gave 2.3315 grms. of precipitate when similarly treated. The precipitate gave when re-dissolved in water $[a]_D = -20.8$. The filtrate containing 39.5 per cent. real gum gave $[a]_D = -67.5$, so that the least laevo-rotatory gum was precipitated by the alcohol.

The Ghattis apparently are all laevo-rotatory, and give much less alcoholic precipitates than the gum arabic. The precipitation moreover was in the opposite direction, that is, the most laevo-rotatory gum was thrown down by the alcohol. The appended table shows the nature of the precipitates and the respective amounts from two Ghattis and two gum arabics. It will be observed that the angle of rotation in three of the cases is decidedly less both for precipitate and filtrate than for the original solution:—

SPECIFIC ROTATORY POWERS OF GUMS.

The hygrometric nature of a gum or dextrin is a point of considerable importance when the material is to be used for adhesive purposes. The apparatus which we finally adopted after many trials for testing this property consists simply of a tinplate box about 1 ft. square with two holes of 2 in. diameter bored in opposite sides. Through these holes is passed a piece of wide glass tubing 18 in. long. This is fitted with india-rubber corks at each end, one single and the other double bored. Through the double-bored cork goes a glass tube to a Woulffe's bottle containing warm water. A thermometer is passed into the interior of the tube by the second hole. The other stopper is connected by glass tubing to a pump, and thus draws warm air laden with moisture through the tube. Papers gummed with the gums or dextrans, &c. to be tested are placed in the tube and the warm moist air passed over them for varying periods, and their proneness to become sticky noted from time to time. By this means the gums can be classified in the order in which they succumbed to the combined influences of heat and moisture. We find that in resisting such influences any natural gum is better than a dextrin or a gum substitute containing dextrin or gelatin. The Ghattis are especially good in withstanding climatic changes.

Dextrans containing much starch are less hygroscopic than those which are nearly free from it, as the same conditions which promote the complete conversion of the starch into dextrin also favour the production of sugars, and it is to these sugars probably that commercial dextrin owes its hygroscopic nature. We have been in part able to confirm these results by a series of tests of the same gums in India, but have not yet obtained information as to their behaviour in the early part of the year.

The fermentation of natural gum solutions is accompanied by a decrease in the viscosity of the liquid and the separation of a portion of the gum in lumps. Apparently those gums which contain most sugar, as indicated by their reduction of Fehling's solution, are the most susceptible to this change. Oxalic acid is formed by the fermentation,

which by combination with the lime present renders the fermenting liquid turbid, and also some volatile acid, probably acetic.

We have made some experiments with a gum which readily fermented—in a week—as to the respective value of various antiseptics in retarding the fermentation. Portions of the gum solutions were mixed with small quantities of menthol, thymol, salol, and saccharin in alkaline solution, also with boric acid, sodium phosphate, and potash alum in aqueous solution. Within a week a growth appeared in a portion to which no antiseptic had been added; the others remained clear. After over five months the solutions were again examined, when the following results were observed:—

Antiseptics.	Solution after Five Months.
Menthol in KOH.....	Some growth at bottom, upper layer clear.
Thymol in KOH	Growth at top, gum white and opaque.
Salol in KOH	Growth at top, gum black and opaque.
Saccharin in KOH ...	White growth at top.
Boric acid.....	Remained clear; did not smell.
Sodium phosphate ...	Slight growth at top.
Potash alum	Slight growth at top.

The solution to which no antiseptic had been added was of course quite putrid, and gave the reactions for acetic acid.

In the earlier part of this paper we have given a short account of the chief characteristics of the more important gum substitutes. The following additional notes may be of interest.

The ashes of most gum substitutes, consisting chiefly of dextrin, are characterised by the high percentage of chlorides they contain, due no doubt to the use of hydrochloric acid in their preparation. The soluble constituents of the ash consist of neutral alkaline salts, but as a rule no alkaline carbonates, and it is thus possible to demonstrate the absence of any natural gum in such a compound. We have seldom noticed the presence of any sulphates in such ashes, but when sulphurous or sulphuric acids have been used in the starch conversion it will be found in small quantities.

We have already pointed out that the potash absorption value of a gum is low and that dextrans give high numbers, but the latter vary very considerably, and as the starch and sugar present also influence the potash absorption value, it does not give information of much service. The following table shows the kind of results obtained:—

Sample.	KOH absorbed.	Starch.	Real Gum.
		Per Cent.	Per Cent.
Dextrin, 1	25.40	1.99	..
Dextrin, 2	19.70	13.13	..
Dextrin, 3	7.57	24.72	..
Artificial gum, 1	19.70	10.98	9.06
Artificial gum, 2	13.70	8.05	23.50
Starch	9.43	100.00	None

The baryta absorptions seem to be chiefly due to the quantity of starch present in the composition:—

Sample.	Starch.	BaO absorbed.
	Per Cent.	Per Cent.
Dextrin, 1	1.99	1.75
Dextrin, 2	13.13	3.53
Dextrin, 3	24.72	5.64
Starch.....	100.00	23.61

The viscosity of a dextrin or artificial gum is determined in exactly the same way as a natural gum, using 10 per cent. solutions. It would probably be an improvement to use 10 per cent. solutions for many of the dextrans, as they are when low in starch extremely thin.

The hygroscopic nature of dextrans renders them unsuitable for foreign work, but when the quantity of starch is appreciable, better results are obtainable. A large percentage of unaltered starch is usually accompanied with a small percentage of sugar, and no doubt this is the explanation of this fact. An admixture containing natural gum of course behaved better than when no such gum is present. Bodies like "arabid" made up with water and containing gelatin are very hygroscopic when dry, although as sold they lose water on exposure to the air. Gum substitutes consisting entirely of some form of gelatin with water, like fish glue, are also somewhat hygroscopic when dried. The behaviour of these artificial gums and dextrans on exposure to a warm moist atmosphere can be determined in the same apparatus as described for gums.

The process we have adopted for estimating the glucose starch and dextrin in commercial gum substitutes is based on C. Handl's method for the assay of brewers' dextrans (this Journal, 8, 561). A weighed quantity of the dextrin is dissolved in cold water, filtered from any insoluble starch, and then the glucose determined directly in the clear filtrate by Fehling's solution. The real dextrin is determined by inverting a portion of the filtered liquid with HCl, and then determining its reducing power. The starch is estimated by inverting a portion of the solid dextrin, and determining the glucose formed by Fehling. After deducting the amounts due to the original glucose and the inverted dextrin present, the residue is calculated as starch. A determination of the acidity of the solution is also made with decinormal soda, and results returned in number of cc. alkali required to neutralise 100 grms. of the dextrin. Results we have obtained using this method are embodied in the following table:—

ANALYSIS OF GUM SUBSTITUTES.

No.	Glucose.	Dextrin.	Starch.	Moisture.	Gum.	Ash.	Acidity.
					Ac.		cc.
1.	8.92	81.57	1.99	10.17	N. 66	0.267	57.3
2.	7.16	71.46	13.11	10.46	N. 66	0.129	44.8
3.	1.26	6.42	24.72	3.17	1.12	0.250	5.22
4.	8.46	6.68	16.88	16.69	9.02	0.539	20.0
5.	1.60	41.8	8.95	12.0	11.57	0.600	52.0
6.	14.56	31.7	16	74.87	1.83	0.586	8.0
7.	8.09	7.61	6.78	17.98	0.88	0.750	88.0
8.	0.29	1.8	1.07	N. 66	7.45	0.315	9.6

In those cases in which the substitute is made by admixture with gelatin or fish glue the quantity of other organic matter obtained can be checked by a hydrolol determination of the total nitrogen. If a natural gum is added it will be partially converted into sugar when the filtered liquid is inverted, and so make the dextrin determination slightly too high.

DISCUSSION.

The CHAIRMAN, in a very discussion on the paper, complimented Dr. Kidel upon his admirable abstract of a voluminous manuscript, which had appeared not only to be practically incapable of condensation.

Mr. BERTRAM BLOUNT wished to say a word or two with respect to the authors' method of determining viscosity. It was preferable to take the viscosity while the oil or other liquid was flowing out under a constant known pressure rather than while flowing out under a varying pressure. There was a well-known method for maintaining a constant head, and when that method was employed the flow was quite regular, the difficulty referred to in getting the last

drops out did not present itself, and the precision of the entire operation was greatly enhanced. The reduction of the various viscosities to an absolute standard by comparison with water was by no means necessary, as an arbitrary standard could be adopted. But it was essential, he thought, to allow the liquid to flow out under a constant head; and he would have appreciated the author's determinations much more highly had that condition been fulfilled.

Mr. THOS. CHRISTY exhibited a sample of a product made in Germany from the Ghatti gum referred to in the paper. This product, he said, had the well-known properties of gum arabic, and he had therefore hoped that the authors would have given some account of it. He had shown the sample to the lecturer before the meeting, and was surprised to learn that he had not seen it before. They had heard that these Ghatti gums were sent over mixed; that was because the Indians, having a great demand for these products, sent men into the forests to collect them indiscriminately in the best way they could. He had himself sorted the gums, and had endeavoured to secure a supply of certain specified varieties, but had failed to do so, because it was found to be quite impossible to control the picking in Indian forests. The German manufacturers of these gums found no difficulty in disposing of them, and when the price of raw gum went down to 4l. per ton they bought largely, and were able to make contracts in advance in this country. In fact, until the recent arrival in this country of gum arabics of good quality from the Niger Company, we had had to depend upon the Germans and Austrians for the supply of reliable gums for envelope making, &c.

Mr. A. BOVRY said that he had been for years past endeavouring to obtain a reliable method for ascertaining the viscosity of fish glue solution. In the case of that substance, however, a 10 per cent. solution would be quite impracticable, as it would not pass through a capillary tube; and if the solution was reduced to half that strength the results bore no definite proportion to one another. Then, again, the question of temperature was a great difficulty. In the case of the material in which he was interested, if the temperature was raised so as to make it possible to pass it through a capillary tube the substance itself was destroyed. He would be very glad if the reader of the paper could give him any information as to the best means of dealing with such a material.

Dr. RIDGE, having been called upon to reply, said that in regard to Mr. Blount's objection, in trying to be brief he was afraid he had not described the form of the apparatus employed sufficiently. The experiment was conducted, not exactly at a constant pressure, but still at a mean pressure. They noted the time taken by the liquid in flowing from the upper to the lower mark on the apparatus. If the bottle was large the alteration of pressure during the experiment was very small. Taking it, say, at 102 mm. at the beginning, it would diminish to 98 mm. at the end; so that the mean pressure would be 100 mm. As to getting the last drops out of the burette or ordinary viscosity apparatus, the necessity for that was obviated by the use of the safety bulbs (Fig. B). The volume that ran through the capillary would be the volume between the two marks.

Mr. BERTRAM BLOUNT admitted that that was so. But the other defect remained, and as it could easily be overcome, it was a pity that the slight modification necessary to that end should not be made, and the apparatus thus rendered perfect.

Dr. RIDGE replied that the reason that was not done was that a different pressure was sometimes required, especially in the case of strong solutions, but he admitted that a constant pressure arrangement could be used if it was wished for.

Continuing, he said that the sample shown by Mr. Christy appeared to him to be an insoluble Ghatti gum which had been rendered soluble. Such gums could be got to dissolve in potash or lime in the laboratory, and they would sometimes dissolve to a certain extent if treated by steam under pressure. In the case of gum tragacanth patents had been

taken out for rendering it soluble by frying it in oil; but until Mr. Christy had mentioned it, he had no idea that a process was at work satisfactorily for the insoluble Indian gums. With regard to the determination of the viscosity of fish glue, of course it was difficult to deal with strong solutions in a burette; but it was quite possible to make the determination in a short time if pressure and the apparatus described was employed. The difficulty consisted in keeping the solution clear, so that it should run through the burette or other instrument employed without stoppage, filter paper being, of course, useless. That difficulty could be overcome by using a battery of capillary tubes through which the solution could be drawn by aid of the pump before use in the viscosimeter.

MR. A. NORMAN TATE IN THE CHAIR.

AN INTERESTING POINT FOR CHEMICAL MANUFACTURERS IN THE NEW GERMAN PATENT LAW.

BY JOHN HAYES.

IN November 1886 a notice appeared in an official international publication, "La Propriété Industrielle," stating that the representatives of German chemical industry were under the impression that, since only the process for manufacturing a new product and not the product itself could be patented, the process might be worked abroad and the products introduced into Germany with impunity.

Section 1 of the 1877 German patent law states what kinds of inventions can be patented and what not. Among the latter are "substances produced by chemical means in so far that the invention does not relate to a particular process by which the substances are produced." It was this provision which occasioned the complaints of the German chemists, and it was admitted at the time that there was ground for them. They had the effect of producing from the German ex-Chancellor a circular on the question (which he addressed in August 1886 to the various Federal Governments), combatting the views of the manufacturers which he attributed to a wrong interpretation of certain words in the law.

After October next, when the new German patent law comes into force, there will be no longer any ground for complaints on this head, as paragraph 4 of the new law

now states directly and definitely (this Journal, 1891, 491) that a German patent which is granted for a process will also extend to the products obtained by such process; and paragraph 35 of the same law further states (*id.* 494) that when the substances produced by a patented process are new substances, then any substances of similar constitution or nature ("Beschaffenheit") is to be regarded as having been produced by the patented process until there is proof to the contrary; showing that an endeavour has been made to meet the views of the chemical trade.

Possibly certain passages of the 1877 law might be construed in such a way (and this construction had the support of the ex-Chancellor) as to give sufficient protection to manufacturers against products illicitly produced. Nevertheless, it is a good thing for the chemical trade that it has now been clearly and definitely laid down that the patent covers the product; or in other words, that although the process, as under the 1877 law, still remains the thing to be patented, yet after October next the patentee has a claim to all products produced by his process without his consent.

The burden of proving that a product has been produced by his process will be on the patentee, but with this very important exception, that he will be relieved of such burden when the product is a new one, in which case the burden of proof will lie on the other party.

magnesia. The application of heat considerably reduces the time required for precipitation as compared with the same treatment cold. According to the original state of hardness of the water and to the amount of impurities it contains, the treatment differs, as does also the arrangement of the apparatus employed, which is further influenced by the use to which the purified water is to be put, whether for steam boilers, laundries, dyeworks, for alimentary or general household purposes. The 17 illustrations accompanying the specification show a variety of apparatus of which the selected figure represents a household lamp with water softener combined.

The underside (u^1) of the vessel (v) is cone-shaped and acts as reflector for the lamp, the chimney (u^2) adds to the heating surface. A circular filter (u^3) separates the vessel into two compartments, and the hard water mixed with any desired ingredients rises through the internal tube (u^4) of the stand, enters the enclosed space, is heated, and, after passing through the filtering material, descends for utilisation through the annular space (u^5) of the stand. There are 18 claims, and for further particulars the specification should be consulted.—B.

Improvements in and Relating to Apparatus for Filtering Water. W. J. Baker, Huddersfield. Eng. Pat. 9802, June 24, 1890. 11d.

IN connexion with the filtration of considerable quantities of water under pressure, the inventor discards the use of large cylinders and employs instead a number of small cylindrical filtering vessels, for the purpose of facilitating inspection and cleaning. The filtering tubes are placed by preference upright between two systems of pipes, the impure water entering through the lower set and the filtered water leaving through the upper, each filter being separately detachable. An open filter is also used in connexion, for the purpose of removing the coarser impurities from the water before entering the system. There are six sheets of drawings and five claims.—B.

Improved Means and Appliances for Manufacturing Glass Tubing and for Coupling together such Tubing. D. Rylands, Stairfoot. Eng. Pat. 10,348, July 4, 1890. 8d.
See under VII., page 643.

Improvements in Apparatus for Distilling Sea-Water and supplying Fresh Water to Marine Boilers, or for other purposes. J. Gilmour, Glasgow. Eng. Pat. 10,379, July 4, 1890. 8d.

SEA-WATER, by preference warmed, such as it issues from the casing of a surface condenser, is evaporated in an independent vessel by means of pipes heated by steam taken either from the main boilers or after having passed through the high pressure cylinder of the engines. The steam arising from the sea-water may be led to the valve chamber of the low pressure cylinder where it joins the expanding steam and gives out work. Or if led direct to the condenser from the evaporating vessel it creates a vacuum in the latter and thus conduces to economy. In either case its condensation replenishes the boiler feed, and it may also be treated partially for drinking purposes to the saving of separate distilling apparatus. There are two sheets of drawings and three claims.—B.

Improvements in and relating to Pyrometers or Thermometers. J. Murrie, Glasgow. Eng. Pat. 10,380, July 4, 1890. 8d.

THIS invention relates to thermometers or pyrometers, in which the heat to be registered is imparted to one end of a closed tube containing a liquid which, by its expansion and pressure, acts upon a yielding medium at the other end of the tube, and through its means moves the index or pointer of the register.

The improvements relate to the manufacture and construction of the apparatus, and consist in making the tube of solid drawn steel, plugged at the inner end, in bending the tube downwards at the outer end where it joins the

indicator or gauge, for the purpose of retaining at the inner or heated end all gases that may be developed. Further, in bending backwards and twisting the inner end of the tube, in sheathing or encasing the free length of the tube, in interposing a diaphragm and separate mercury chamber between the heated liquid and the gauge, and in various other details for aiding correct indication as represented by two sheets of drawings and nine claims.—B.

Improved Apparatus for Drying and Mixing Bones and other Substances. A. H. Hobson, London. Eng. Pat. 10,562, July 8, 1890. 6d.

A CYLINDER mounted on an inclined axis is provided internally with sets of partitions or "baffles," which are semi-circular in shape and reach about half-way across the cylinder. The baffles are, more or less, inclined to the axis of the cylinder, being either fixed or regulated from the outside, and so arranged that the edges of one set come opposite the intervals of the other set. Any substance fed into the upper end of the cylinder will thus be compelled to take a zig-zag, up and down course through the apparatus, and be thoroughly mixed. The lower end of the cylinder passes into a chamber provided with a balanced door for the exit of the substance undergoing treatment and with an inlet for hot air or flue gases for drying the material as it passes through the apparatus.—H. T. P.

Improvements in or connected with Apparatus for Drying Granular Substances. J. H. R. Dinsmore, Liverpool. Eng. Pat. 10,888, July 12, 1890. 8d.

THE object of this invention is to provide a more simple, rapid, and effective mode of drying granular substances such as wheat, brewers' grains, &c.

The grains are enclosed, by preference, in a horizontal cylinder (or cylinders), provided internally with pockets or scoops set in a vertical direction. The cylinder, on being made to revolve, elevates and turns the grain over or through a system of heated pipes extending over a greater part of the length of the cylinder, the moisture or vapour given off being removed by a current of air produced by a fan placed in the space between the end of the heating pipes and the outlet end of the cylinder. The grain is afterwards cooled in the above space or in a separate cylinder into which the grain is discharged by a shoot. Heated gases or fluids may be used, if desired, instead of steam.—E. S.

Improvements in Evaporating Apparatus, Specially adapted for the Extraction of Salt from Brine. A. Chapman and S. Viekers, jun., Liverpool. Eng. Pat. 11,529, July 23, 1890. 8d.

See under VII., page 641.

Improvements in Apparatus for Straining or Sifting Finings and other Analogous Materials. C. O. Gridley, London, and A. Bishop, Walthamstow. Eng. Pat. 11,672, July 25, 1890. 6d.

AN inverted conical sieve, formed of wire gauze or other suitable material, is fixed by its base to the upper end of a cylindrical vessel used for collecting the materials after passing through the sieve. Another cylindrical vessel is mounted and fixed upon the sieve, and holds the materials to be operated upon. A vertical shaft, carried by suitable bearings, is fitted to the cylinder and sieve, and carries a spiral screw consisting of three or more helices corresponding to the form of the sieve. The bearings are made adjustable so that the spiral screw can be placed nearer to or further from the inner surface of the sieve as desired. The materials to be operated on being placed in the upper cylinder the screw is revolved, and the materials are passed through the meshes of the sieve and brought to the requisite degree of fineness. Meshes of various sizes are used, according to the nature of the materials and the fineness required.—E. S.

Improvements in Methods of Treating Heated Liquid Wastes, and Apparatus therefor. E. Nelson, New York, U.S.A. Eng. Pat. 3445, February 25, 1891. (By Internat. Conv. August 30, 1890.) 8d.

By means of this apparatus, the waste hot water and partially condensed steam, mixed with more or less lubricating material, derived from the leakage of steam-cocks, valves, &c., may be utilised. The "drips" from various sources are collected by means of branch pipes into a main dripe-pipe, which enters the bottom of a closed cylinder called an "extractor," terminating within it at a height equal to about two-thirds of the distance from the top to the bottom of the vessel. A second pipe issues from the bottom of the extractor, and terminates in a water-trap, which serves to maintain the liquid within the apparatus at a constant level. This pipe is bent on itself several times like a condenser, and is provided with a water-jacket. The oil which floats to the top in the extractor is drawn off from time to time; whilst the hot water passing off through the pipe at the base of the cylinder serves to warm the boiler feed water which is made to circulate through the jacket surrounding the pipe.

For treating large quantities of waste, especially when contaminated with much oil, the apparatus is somewhat modified. Two extractors are employed, the liquid being partially cooled in its passage from the first to the second of them. For drawings of the apparatus the original specification must be consulted.—H. T. P.

Improved Method of and Apparatus for Regulating the Egress of Spent Liquor from Distilling Apparatus. M. Schwab, Manchester. Eng. Pat. 6317, April 13, 1891. 6d.

This invention is for the purpose of maintaining the level of the liquid in the distilling vessel at a constant height, and consists in the addition of a separate vessel containing a valve which may be kept on its seat by its own weight or by a spring. This outside vessel is connected with the distilling vessel by a pipe, through which the excess of liquor flows under the automatic control of the valve.

PATENTS.

Improvements in Apparatus for Burning Liquid Fuel. W. F. Smith, Brighton. From S. I. J. Bray, Moscow, Russia. Eng. Pat. 1246, March 18, 1890. 11d.

This invention is designed for the purpose of atomising hydrocarbon and other oils as fuel in steam-boiler and other furnaces. One of the improvements consists in providing means for simultaneously mixing the oils with air and steam before combustion, thereby effecting a saving of steam and diminishing the quantity of air which has to enter the furnace in order to support combustion. Another important feature consists in providing a series of cross pieces or wires, or netting, against which the sprayed vapourised or atomised hydrocarbons are thrown, thereby causing the air to intermingle with the already formed gases

and producing a broad and economical flame resembling that produced by wood, coal, or other fuel in an ordinary furnace or combustion chamber.

This ensures a more economical combustion of the fuel and a less detrimental effect upon the furnace walls or boiler-plates than is produced by the usual "blow-pipe" form of flame which impinges constantly upon the same spot.

This improved burner can be easily fitted to existing furnaces or boilers. It makes no objectionable noise, and has the further advantage that the combustion takes place at some distance from the mouth of the shield, thus preventing the rapid deterioration from overheating to which such burners as hitherto constructed are liable.—D. E. J.

Improvements in the Production of Water-Gas. J. Blum, Berlin, Germany. Eng. Pat. 5239, April 5, 1890. 8d.

This is a process for the production of water-gas by the interaction of hydrocarbon, preferably petroleum and water, in the presence of a metal, preferably nickel, cobalt, or copper. The hydrocarbon and water must be intimately mixed in the proportion required for their mutual decomposition. The requisite temperature is not less than 570° F. for nickel, 630° F. for cobalt, and 850° F. for copper. An apparatus is described, in which the petroleum and water are delivered in the right proportion to a heated chamber containing metallic wire, the supply of fluids being regulated by the pressure of the water-gas produced.—H. K. T.

Improvements connected with the Manufacture of Water-Gas and other Gases for Lighting and Manufacturing Purposes. H. Williams, Stockport. Eng. Pat. 5434, April 10, 1890. 11d.

This invention relates to "apparatus for generating that class of gas composed of a combination of hydrogen gas produced from the decomposition of superheated steam, carbonic oxide gas, gas produced by the distillation and carbonisation of coal or wood, and gas produced from liquid hydrocarbons." By preference, a set of two vertical furnaces lined with fire-brick is used. The furnaces communicate with each other by ducts controlled by valves, and each furnace is surmounted by a small retort, also communicating with it by a suitable valve. One condenser (consisting of a group of pipes of small diameter) is used in conjunction with the pair of retorts. In connexion with the furnaces is a carburetter, wherein the gases may be diffused with the vapour of liquid hydrocarbons to any required degree of illuminating power, and afterwards fixed into a permanent gas. This fixing apparatus consists of an iron brick-lined chamber, within which are arranged a group of retorts or pipes charged with iron or steel trimmings or scraps loosely packed, surrounding the chamber or adjacent thereto is a multiple carburetter, in which the gases are intimately mixed with hydrocarbon vapours prior to their introduction into the carburetting retorts and fixers. The process is practically a continuous one. The furnaces are charged with coke, coal, or charcoal, and the retorts above them are charged with bituminous coal or wood. The fuel in the furnaces is brought to incandescence by forcing air through them, and the producer gases (at a high temperature) are passed into the carburetting chamber, thus raising the carburetting retorts and fixers to the high temperature required to enable them to carry out their functions of carburetting and fixing the gases permanently. For details the specification and its four sheets of drawings must be consulted.—D. E. J.

Improvements in or connected with the Manufacture of Water-Gas. J. von Langer and L. Cooper, Leeds. Eng. Pat. 7739, May 17, 1890. 11d.

The object of this invention is to produce water-gas more economically in those cases where the generator-gas obtained at the same time cannot be separately made use of, and also to provide a simple means for removing undecomposed steam from the water-gas.

The first object is attained by employing a recuperator of the class previously described (Eng. Pat. 6400 of 1890), in which the producer-gas from the generator is burnt; the products of combustion are employed for heating air, some of which is used in the generator and some to supply the required amount for the combustion in the recuperator.

The hot water-gas is freed from steam by passing it through a coke stack on its way to the scrubber. (See also this Journal, 1890, 170; 1891, 245 and 452.)—F. S. K.

Improvements in and Apparatus for the Manufacture of Gas for Lighting and other Purposes. E. W. Walker, London. Eng. Pat. 8373, May 30, 1890. 8d.

COAL-GAS, produced in the usual way, is passed through condensers and washers, and then into carburetters; before drawing the charge, steam is admitted to keep the retorts free from carbon, and the gas produced is either led into the main, or, should the sulphur be objectionable, discharged elsewhere. The hot coke is then withdrawn and placed in water-gas producers, arranged in batteries of two, and there treated with superheated steam, the gas being passed into the same carburetters as the coal gas. The percentage of carbonic oxide in the finished gas may be reduced by the addition of hydrogen, which is obtained from spongy iron and steam; the hydrogen is passed into the same carburetters as the other constituents. All the retorts, chambers, &c. may be arranged in a furnace of any convenient form.—F. S. K.

Improvements in Apparatus for Generating and Burning Mineral Oil Gas for Heating Purposes. O. Linder, Brussels, Belgium. Eng. Pat. 9393, June 17, 1890. 8d.

This invention relates to apparatus in which petroleum is converted into gas by the heat generated by the burning of the petroleum in the apparatus. The petroleum runs under pressure into a valved feed-pipe, which first ascends vertically, is then bent so as to form a horizontal canal, from which a pipe, parallel with the vertical portion, descends for a short distance, and is finally bent upwards towards the axis of the canal, terminating in a jet or burner. The horizontal canal is covered by a dome-shaped, perforated plate, provided with a conical deflector; the object of this arrangement is to throw the heat downwards, so that the canal or evaporating chamber is raised to a high temperature. A spirit vessel, fixed underneath, serves to start the apparatus.

The pressure on the petroleum supply pipe is regulated by means of a water-reservoir, placed above and communicating with an air-reservoir; the air pressure forces the petroleum from a tank into the burner, which is placed at a higher level.—F. S. K.

Improvements in or Relating to the Treatment of Peat for the Production of Fuel and By-products. W. Loé and C. Gumbart, Munich, Germany. Eng. Pat. 9651, June 21, 1890. 8d.

PEAT is dug or dredged, made into blocks and dried on "drying fields" or in kilns heated by the gases from the carbonising kilns to be afterwards mentioned. The drying kiln contains two or more travelling bands, from which are hung slats, so arranged that during the greater part of their course they are kept horizontal by contact with a fixed guide-rail, but towards the end are allowed to drop and hang vertically from the travelling band, dropping their burden on slats similarly hung and guided on the lower side of the band. By the use of the same device of a fixed guide-rail for the greater part of the travel of the band and slats, the peat to be dried is made to traverse the kiln from side to side once more, and then drops in the same way as before on to a second travelling band of construction identical with that of the first.

The dried peat is mixed with well-burnt and newly-slaked lime, and either heated in an ordinary charcoal kiln, if it be not intended to obtain the by-products of its distillation, or in an externally fired charcoal kiln in the contrary case.

A furnace is described which can either be used for the obtaining of by-products or without, in which case the draught is improved.

The temperature at which the carbonising is effected should not exceed 500° (C.?). It is alleged that the lime mixed with the peat "analyses the protein substances, and thereby increases the output of ammonia," and that "the carbonate of lime formed thereby is again burnt by the subsequent heating, and enters into a cement-like connexion with the silicic acid contained in the peat and the silicate of alumina, &c.," which increases considerably the fitness for forming the mixture into blocks. The carbonised substance is cooled with water as it leaves the kiln, ground to a stiff paste, and pressed into blocks, which are said to form a good fuel, free from smoke and smell, and leaving an ash that may be used as a mortar or a manure. The by-products, chiefly acetic acid, ammonia and tar, are collected by known means.—B. B.

Improvements in Gas Producers. J. E. Bott, Eym, W. Mortimore, Manchester, and F. H. Lindley, Reddlyffe. Eng. Pat. 11,106, July 16, 1890. 11d.

THE improved producer consists of a circular vertical casing of wrought iron, lined with refractory materials. The hearth is so constructed that there are three ash-pits of water, intersected at equal distances by three iron tuyère chambers, which connect with the blast chamber by channels in the casing of the producer; the communication between the tuyères and the blast chamber is so arranged that when the tuyères are in use the openings are in juxtaposition, and when the tuyères are withdrawn to be cleaned the blast is shut off automatically.

The blast is admitted into the fuel through ports at the sides of the tuyères at some distance from the centre of the producer, the space in the centre being composed of refractory material on which unburnt coal continually drops. The tuyères are made in two parts, the upper of which slides, like a drawer, over a supporting trough, its sides and bottom being in contact with water. The escape of gas through the stoking holes is prevented by using ball-valves, constructed with a centre hole, through which the stoking rods are passed; when not in use the holes are closed by turning the balls.

The advantages of this form of producer are, amongst others (1) the production of gas is more regular; (2) the tuyères are prevented from too rapid destruction, and can be cleaned and repaired while working; and (3) a richer gas is produced.—F. S. K.

Improvements in the Manufacture of Artificial Fuel. R. Schimper, Jersey City, U.S.A. Eng. Pat. 12,639, August 12, 1890. 4d.

THIS is said to be a fuel composition to be burnt in a flueless stove or other vessel, such fuel burning slowly without giving flame, smoke, or "obnoxious gases." It consists of a mixture of 100 lb. of pulverised charcoal or coke, 3½ lb. of nitre, and 3 lb. of starch. These are mixed into a paste with water, ½ lb. of brownstone is added, and the composition is then pressed into blocks. The fuel, when burnt, leaves 5 per cent. of ash. The brownstone "serves to absorb and neutralise any smell" produced by the combustion of the starch and serves to retard the burning.—H. K. T.

Improvements in Means employed in the Manufacture of Hard Coke, the Distilling of Shale, the Roasting of Ores, or other Operations wherein Carbonaceous Matter is subjected to the Action of Heat. L. H. Armour, Gateshead-on-Tyne. Eng. Pat. 14,052, September 6, 1890. 6d.

THE patent relates especially to ovens such as are described in Eng. Pats. 1947 and 5032 of 1882 (see this Journal, 1890, 488; 1891, 436—443). "Water or liquid" is supplied under the charge in regulated quantity, the pipes or conduits through which it is supplied being provided with a water-seal and preferably with a sight feed arrangement. The

patentee proposes to use two inlet pipes, one of which should be as near as is practicable to the exit for the gaseous products of the material under treatment.—B. R.

Improvements in or relating to Burning Petroleum and other Hydrocarbons, and Apparatus connected therewith. W. T. Thompson, Liverpool. From A. Mason, Brooklyn, and J. W. Son, New York, U.S.A. Eng. Pat. 16,762, October 21, 1890. 1. 4d.

This invention relates (*inter alia*) to a method of burning hydrocarbon fuel which consists of injecting a portion of the same into the upper portion of the furnace chamber, and at the same time maintaining a distinctively separate fire of heated jets of oil in the lower space, upwardly and locally impinging their products on the laterally projected fire. Reference is made to a prior patent (Eng. Pat. 4241 of 1875) in which carburized air or gas are introduced from below, together with injected oil spray "above the level of the fire bed." It is pointed out that in this prior patent the two elements are in such close proximity that there is practically only one fire in which both elements are combined; whereas in the present patent it is the distinctively separate upper and lower fires that are relied upon. By their use the best results are obtained; smoking, clogging up, and choking of the furnace grates do not occur; and the mutual support of the cross fires provides an effectual preventative of the sudden interruption of the fire which is common in the burning of oil in one fire only from such causes as momentary stoppage of the oil supply by clogging, &c.

Any drippings from the injector are retained by a bed consisting of asbestos, porous stone, or other refractory and absorbent material. To this refractory bed a further supply of oil may be conveyed. Air or air and steam may also be admitted below the said bed.

The invention further relates to a method of burning liquid hydrocarbon fuel which consists of injecting oil, steam, and air into a pipe, retort and maintaining them for a time therein subject to the heat of the combustion chamber for mixing, expanding, vaporising, and gasifying them therein.—D. E. J.

Improvements in the Manufacture of Gas. T. G. Springer, Chicago, U.S.A. Eng. Pat. 17,159, October 27, 1890. 6d.

This invention relates to the manufacture of gas from the decomposition of steam and heavy hydrocarbon oils, which oils, owing to their low specific gravity, are difficult to treat. The lower part of the apparatus used consists of a furnace with appliances for admitting an air blast and a steam supply. This furnace acts as a fuel and steam decomposing chamber. Above this are two chambers containing refractory material. One of these is a vaporising and mixing chamber into the upper part of which hydrocarbon oil is admitted and allowed to descend, preheating the refractory material. As it descends it meets the upward current of decomposed steam with which it mingles; here there may be a partial decomposition of the oil and fixing of gases. The second chamber is larger than the first, and is used as a fixing chamber for fixing the oil vapours, and water-gas. Between these two chambers and the furnace itself are two combustion chambers for burning the waste gases from the fuel chamber during the blasting of the fuel to incandescence.

In carrying out the process the furnace is first charged, the air blasts are set in action, and the products of combustion from the fuel are caused to heat the apparatus, including the refractory material in the vaporising and fixing chambers. When the fuel is in a state of incandescence the air blast is stopped and steam is admitted beneath the fire bars. The steam is decomposed in passing through the incandescent mass of fuel, and is further heated when it comes in contact with the refractory material in the vaporising chamber. The hydrocarbon oil is now admitted into the latter, drops down and vaporises, its vapour mingling with the water-gas resulting from the decomposition of the steam. After being forced through the fixing chamber the products issue as a fixed gas which can be used for illuminating or other purposes. The operation continues as long as the heat is sufficiently

maintained, but as soon as it becomes too low to properly decompose the steam and oil, the supply of these is cut off, and the blasting operation is repeated until the requisite heat is attained.—D. E. J.

Incandescent Gas Lights. C. M. Langsen, New York, U.S.A. Eng. Pat. 17,674, November 4, 1890. 6d.

PLASTIC wires made of compositions containing refractory earths are woven instead of being wound one above the other, and pressed together. In this way the wires are less liable to cut one another, and the structure is more elastic. To give the thread sufficient plasticity and tensile strength for this purpose, a small quantity of glycerin is added to the glue of which it is composed. Or such substances as rubber dissolved in naphtha, or boiled linseed oil, may be used as binders. In making the threads, the refractory earth is mixed with the binder, and then forced through a die. The wires so produced are then supplied to a weaving or braiding machine.—H. K. T.

Improvements in Coking Processes. J. Bowing, Tilbury. Eng. Pat. 1682, January 29, 1891. 4d.

IN previous patents (Eng. Pats. 10,137 of 1888 and 9199 of 1890) the inventor has claimed the manufacture of briquettes from coal and similar substances by mixing with tar or shale oil and water, and compressing, the mixing being preferably carried out by forcing steam through the mixture, whereby the excess of water and oil are forced out. He now claims the coking of the briquettes prepared as above. The above preparation is very suitable for coking, especially when materials of an anthracite nature, which will not usually coke, are to be dealt with.—H. K. T.

Improvements in Separating Carbonic Acid from other Gases, specially in the Production of Gas for Lighting and Heating Purposes Free, or practically Free, from Carbonic Oxide. P. F. MacCallum, Helsingborg. From J. C. Reissig, La Plata, and J. Landin, Stockholm, Sweden. Eng. Pat. 2021, February 4, 1891. 4d.

WHEN steam is passed through incandescent carbonaceous fuel maintained at 550—750 °C., a gas is produced which consists mainly of hydrogen and carbonic acid, with only small quantities of carbonic oxide. When the fuel is maintained at a higher temperature, the proportion of carbonic oxide increases until, at a temperature of 1,000° the resulting gas consists of a mixture of about 40 per cent. of carbonic oxide and 50 per cent. of hydrogen, with only about 5 per cent. of carbonic acid. This is known as water-gas, and its use is often objected to on account of the poisonous properties of the carbonic oxide contained.

The main object of this invention is to produce a gas containing but little carbonic oxide, and to increase its calorific power by removing the carbonic acid from the combustible gases. The process consists in passing steam (preferably superheated) or water through fuel contained in externally-heated retorts, or in water-gas generators, maintained at 550—750 °C. The resulting gas, consisting of hydrogen and carbonic acid, in the proportion of 2 to 1, is cooled and freed from sulphur impurities in the usual way. It is then passed through an absorbing apparatus containing carbonates of alkali or alkaline earths, preferably solutions of sodium carbonate (soda) or potassium carbonate (potash). These substances readily absorb (especially under pressure) the carbonic acid, forming bicarbonates, from which the carbonic acid is easily removed by the action of a moderate vacuum, especially if aided by heat. The remaining gas consists principally of hydrogen, and is ready for use, while the solutions are again available for unlimited repetition of the absorbing operations, &c.

—D. E. J.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

On the Composition of Certain Petroleum Oils, and of Refining Residues; the Sulphur Compounds in Ohio Petroleum. C. F. Mabery and A. W. Smith. Amer. Chem. J. **13**, 232—243. (See also this Journal, 1890, 275.)

Much difficulty having been experienced in the removal of sulphur from the distillates of Ohio oil, few if any of the commercial products are entirely free from it, while it is frequently present in considerable quantities. The authors have been able to separate and identify in the crude oil methyl, ethyl, normal propyl, normal and iso-butyl, pentyl, ethyl-pentyl, butyl-pentyl, and hexyl sulphides, and also various sulphides which correspond neither in boiling point nor in composition with any previously described, together with some apparently unsaturated sulphur-free oils, which will be further examined.

When the acid sludge from the washing of the various products is diluted and neutralised with lime or chalk, unstable calcium salts are formed, which are decomposed by distillation with steam, the sulphides passing over. This oil is colourless when freshly distilled, and is entirely free from sulphuretted hydrogen. Its specific gravity at 16.5° is 0.9245, and it contains 14.97 per cent. of sulphur. On distillation under atmospheric pressure considerable decomposition takes place, but by reducing the pressure to from 100 to 150 mm. it becomes inappreciable. This decomposition, however, occurs only in the case of the sulphides boiling above 140° (at 760 mm.). By repeated fractionation the oil may be split up into a number of fractions, which give with alcoholic and aqueous mercuric chloride precipitates, crystalline in the case of the more volatile sulphides, thick viscid oils with the less volatile. They also readily form platinum salts and bromine addition products. The lower sulphides may also be obtained from the crude spirit boiling below 150° by precipitation with aqueous mercuric chloride. The heavy precipitate is dried by pressure, and decomposed by sulphuretted hydrogen in presence of alcohol, the mercuric sulphide invariably separating in the red form. After filtration the oil is thrown out by the addition of water, washed, and dried. Thus prepared it is nearly colourless, and has a specific gravity at 20° of 0.8543. From this latter product the authors have prepared methyl, ethyl, ethyl-propyl, and normal propyl sulphides, the remainder of those mentioned above being obtained from the oil from the acid sludge. All attempts to isolate iso-propyl sulphide were unsuccessful, as although some of the distillate collected between 115°—125°, analysis showed that it could not be the iso-compound boiling at 120°. From the sludge oil various sulphur-free oils uniting readily with bromine and those of lower boiling points with hydrobromic acid were obtained.

To remove any doubts whether these sulphides exist in the crude petroleum, the authors distilled several litres under diminished pressure, and extracted various distillates, some with sulphuric acid, and some with mercuric chloride, and obtained sulphides corresponding in all respects to those previously mentioned.

About one-third of the sludge oil distilled above the boiling point of hexyl sulphide, but with considerable decomposition even under diminished pressure. It consisted in great measure of sulphides, but the authors have not attempted to separate them.—F. H. L.

Constitution of Cymene. O. Widman. Ber. **24**, 439—456. The author describes the synthetical preparation of paramethylpropylbenzene and paramethylisopropylbenzene, and

in the following table compares the properties of these isomeric hydrocarbons with those of cymene:—

Paramethylpropylbenzene.	
Boiling point	183—181°.
Specific gravity	0.8682 (15°).
Odour	Pleasant.
Treated with HNO ₃ (1.40)	Does not yield tolylmethylketone.
Ba-α-sulphonate	(C ₁₀ H ₁₃ SO ₂) ₂ O ₂ Ba + H ₂ O, plates; do not lose water at 100°.
Na-α-sulphonate	4 C ₁₀ H ₁₃ SO ₂ ONa + 5 H ₂ O, plates.
α-sulphone-amide	Large plates melting at 102°—103°.
Ba-β-sulphonate	(C ₁₀ H ₁₃ SO ₂) ₂ Ba + 4 H ₂ O, short needles.
β-sulphone-amide	Scales melting at 112—113°.
Paramethylisopropylbenzene.	
Odour	Somewhat unpleasant.
Ba-α-sulphonate	(C ₁₀ H ₁₃ SO ₂) ₂ Ba + 3 H ₂ O, plates, lose all water at 100°.
α-sulphone-amide	Plates, melting at 115°—116°.
Cymene.	
Boiling point	175—176°.
Specific gravity	0.8602 (15°).
Odour	Unpleasant.
HNO ₃ (1.40)	Yields tolylmethylketone.
Ba-α-sulphonate	3 H ₂ O, plates, lose all water at 100°.
Na-α-sulphonate	5 H ₂ O (according to Sieveking) 3 H ₂ O (Paterno).
α-sulphone-amide	Plates melting at 115°—116°.
β-sulphone-amide	Scales melting at 148° (Remsen and Day).

The author concludes from his investigations that cymene is paramethylisopropylbenzene, and not paramethylpropylbenzene as hitherto assumed.—D. B.

Ethylpropylbenzene. O. Widman. Ber. **24**, 456—459.

In a recent communication (Ber. **23**, 3191) von Beeke, in treating ethylbenzene with propylbromide in the presence of aluminium chloride, and fractionating the product, claims to have obtained the following compounds:—Fraction 150—155°: isopropylbenzene. Fraction 178—185°: diethylbenzene. Fraction 189°—195°: *m*-ethylisopropylbenzene. Fraction 195—201°: *p*-ethylisopropylbenzene. Fraction 201°—208°: di-isopropylbenzene. The author argues that it is quite impossible to obtain pure hydrocarbons in this way, and expresses the opinion that in most cases the fractions in question contain mixtures of two or more hydrocarbons. This is clearly shown in the case of ethylpropylbenzene which von Beeke prepared according to Semptowski's method. This, on sulphonation, yields an acid, the magnesium salt of which was converted into the sulphone-amide. The latter melts at 84°. The author, however, positively asserts that on sulphonating the hydrocarbon two sulphonic acids are formed, the corresponding sulphone-amides melting at 112—113° and 108° respectively.—D. B.

History of Cymene. R. Meyer. Ber. **24**, 970—971.

Referring to Widman's researches on the constitution of cymene (preceding abstract), the author considers it necessary to mention that he has at no time entertained the

least doubt as to the accuracy of his own experiments or those of Jacobsen, and for this reason it was unnecessary for him to repeat his former trials. He has not attempted to prepare the hydrolyzation of its sulphonic amides in a pure form as suggested by Widman. The only substance analysed by the author has been the barium salt of para-propyltolylene sulphonic acid, which he, in agreement with Jacobsen, found to contain 1 mol. of H_2O . According to Widman it contains 3 H_2O . It is the author's intention to repeat his former work and if, as he hopes, his results confirm Widman's recent observations, the whole chemistry of the eymene and eumene groups will have been greatly simplified, and further proof adduced respecting the correctness of the conclusions drawn by the author from his researches on hydroxylation. If, as Widman shows, eymene contains iso- and not normal propyl, the only plausible exception to the rule that "tertiary hydrogen atoms" only are convertible directly into hydroxyl falls to the ground and the oxidation of eymene and its sulphonic acid into hydroxy-propylbenzoic and hydroxypropyl-sulphobenzonic acids takes place without any chemical resolution.—D. B.

History of Eymene. O. Widman. Ber. 24, 1362.

A REPLY to Meyer's remarks (preceding abstract) on the same subject calling for no special notice.—D. B.

Syntheses of Carbazole Derivatives. E. Tamber and R. Loewenherz. Ber. 24, 1033-1036.

TAMBER has recently described the synthesis of a diamido-carbazole from benzidine, and has also prepared carbazole synthetically from benzidine. The authors now give an account of the preparation of carbazole derivatives from benzidine homologues.

Diamidodimethylcarbazole, $C_{12}H_{12}N_4$, was obtained by heating metadiamido orthodichloride hydrochloride with 20 per cent. hydrochloric acid (3-4 parts) for 15 hours at 190°, treating the filtered solution of the product with stannous chloride and hydrogen sulphide, evaporating the filtrate and precipitating with hot concentrated hydrochloric acid. The hydrochloride which results crystallises in colourless needles. The base forms colourless microscopic needles. It is almost insoluble in water, sparingly soluble in cold, more readily in hot alcohol, benzene, toluene, and ether. It turns black at 260° and melts at 271°. The *direct product*, $C_{12}H_{12}N_4$, is obtained when the base is boiled for six hours with glacial acetic acid (5 parts). It crystallises from the latter solvent in colourless needles which melt at 300°.

The following constitutional formula represents the synthetic formation of diamidodimethyl carbazole.—

Dimethylcarbazole is obtained by heating orthodiamidodichloride with 20 per cent. hydrochloric acid at 200°, also by removing the amido group of diamidodimethyl carbazole. Both methods yield the same product, which closely resembles carbazole in appearance. From a consideration of the properties and the syntheses referred to, the authors

are satisfied that the compound in question is dimethylcarbazole of the formula:—

The picrate crystallises in reddish-brown needles, melting at 192°. Although it melts somewhat higher than the picrate from carbazole, the dimethyl base obtained therefrom melts at 249°, which is 19° lower than the temperature at which carbazole melts. Unlike the latter, a solution of dimethylcarbazole in sulphuric acid does not give the characteristic greenish-blue colour reaction with nitric acid, nor is it possible to obtain the blue dye by treating the dimethyl compound with oxalic acid.—D. B.

Utilisation of Dorsetshire Shale. Chemist and Druggist.

A SCOTISH Company has started the manufacture of a new disinfectant and deodorant, from an uncommon kind of blackstone shale found at the Dorset mines. Composed altogether of animal and vegetable remains, this shale is remarkably light, yet it contains oils of a very heavy and volatile character. When distilled these oils are declared to possess valuable insecticide and deodorant qualities. The shale is found at a depth ranging from 300 to 500 ft. below the surface of the ground, and contains the remains of saurians and other extinct animals. The oil is extracted from the shale by distillation, and the residual product is reduced to different sizes of grain, ranging from a fine black powder to granules the size of an ordinary pea. The oil, mixed with other substances, is stated to form a manure, combining the double qualities of a good fertiliser and powerful insect killer.

PATENTS.

Improvements in the Apparatus for Destructive Distillation of Mineral Oils. J. Laing, Edinburgh. Eng. Pat. 11,079, July 16, 1890. *Id.*

THIS invention relates to the destructive distillation of mineral oils in such a manner as to convert them into oils of light specific gravity. Its essential feature is a "superheater," which is a metallic vessel of any convenient form, used in conjunction with the "primary oil still" which may either be of ordinary construction or of that described by the author (Eng. Pat. 4120 of 1890; this Journal 1891, 534).—A. R. L.

Improvements in the Treatment of Crude Blast Furnace or Coke Oven Oils, and Application of the Oils so Treated or Produced for Making or Enriching Illuminating Gas. W. W. Staveley, Pontefract. Eng. Pat. 11,195, July 18, 1890. *Id.*

WHEN "crude or once run" blast furnace or coke oven oils, containing varying quantities of phenol, cresol, and their higher homologues, together with hydrocarbons of the paraffin series and pyridine bases, are fractionally distilled in an ordinary still or retort provided with a dephlegmating column, similar to Couper's benzene apparatus, but constructed mainly of cast-iron, a distillate boiling at 220°-250° (thermometer in vapour), and usually amounting to 50 per cent. of the original oil is obtained. It contains about 50 per cent. of phenol, cresol, &c., 47 per cent. of "light paraffin oils and bases," and 3 per cent. of water. The author claims the economic production of an oil—as above described—which yields on destructive distillation benzene, toluene, &c., the latter being better adapted to increase the luminosity of illuminating gas than the original oil.

When the "improved oil" is used for manufacturing illuminating gas, it is heated in a retort to a high temperature, and the resulting gases, after cooling, collected in a

suitable holder; or (preferably) the oil is passed in a stream or spray into a heated retort through which coal-gas or water-gas is passing, when the vapours of benzene, toluene, &c. are taken up and held as permanent gas by the latter; "the oil may be sprayed into the retort by means of compressed coal or water-gas."—A. R. L.

Improvements in the Apparatus for Destructive Distillation of Mineral Oils. J. Laing, Edinburgh. Eng. Pat. 11,757, July 28, 1890. 6d.

This invention relates to the treatment of mineral oils by destructive distillation under high pressure, in order to convert them into "lighter products." The "primary oil still" may be one of ordinary construction or of that described by the author (Eng. Pat. 4120 of 1890; this Journal, 1891, 534). The patentee claims "the combination with a still for the destructive distillation of mineral oils, of a loaded outlet valve and a relief tank interposed between the said outlet valve and an ordinary condenser, the said relief tank being used more or less as a condenser." The pressure to which it is requisite to load the valve depends upon the nature of the oil, and may be ascertained by trial; the patentee believes that to obtain an oil having a specific gravity of 0.700, from one of specific gravity 0.970, a pressure of about 80 lb. per square inch will be necessary. (See also Eng. Pat. 11,079 of 1890; preceding page).

—A. R. L.

Improvements in the Continuous Distillation of Hydrocarbon and other Oils and Liquids. C. M. Piel-ticker, Harlesden. Eng. Pat. 1308, January 24, 1891. 8d.

This invention relates to improvements by which the distillation of hydrocarbons and other oils and liquids can be conducted in a continuous manner. In a previous patent (Eng. Pat. 1706 of 1882) the author described a method in which the oil was forced by means of a pump or steam injector into a coil open at the other end, in which coil the oil was heated to its distilling point, the heated oil entering from the coil into a heated retort in which it was vaporised and afterwards condensed in a cooler connected with the retort. With this apparatus it was found difficult to regulate the temperature of the coil so that all the oil at once assumed the form of vapour on entering the retort, while at other times the coil became so superheated that a portion of the oil was converted into permanent gas. Moreover, the coil being directly exposed to a high temperature, was soon burned through, and it was impossible to clear the coil from the carbon deposited in it.

These defects were partly obviated by improvements described by the present patentees in Eng. Pat. 6466 of 1890 (this Journal, 1891, 456), and are more perfectly removed in the apparatus now described. The oil is heated in the tank by means of a steam coil, and from this is forced by means of a pump into the heating coil. Between the pump and the inlet to the coil a steam connexion is provided for the purpose of emptying the oil contained in the heating coil at the end of the operation by means of a steam blast into a retort into which the other end of the coil leads; otherwise, when the pumping is stopped the oil remaining in the heating coil would speedily become carbonised and choke the coil. The retort is provided with a number of baffle plates causing the oil vapours to take a lengthened passage through the retort, a passage being left in the baffle plates to allow of the flow of tar or residuum. For removing this, a valve is fitted at the lower end of the cover, a steam inlet being connected with the tar outlet, in order to blow steam when the outlet is opened. This not only assists in the removal of the thick tar, but more particularly prevents the entry into the retort of air, which would form a dangerously explosive mixture with the gases. The vapours are led through a dome into the condensing pipe, which reaches nearly to the bottom of the first of a series of condensing vessels in which the heaviest vapours condense. In the succeeding vessels oils of gradually diminishing specific gravities condense. If the manufacture of permanent gas or very light oil is desired the retort is

directly connected with a second heating coil similar to the first one, and superheated steam is simultaneously injected into this second coil by means of a steam injector. The apparatus may be used for the distillation of other liquids besides hydrocarbons; for instance, for fats and oils in the separation of fatty acids and glycerin.—D. E. J.

IV.—COLOURING MATTERS AND DYES.

Cochineal-Carmine. F. Lafar. J. Prakt. Chem. 43, 130—138.

From the results of an analytical examination of carmine, Liebermann (this Journal, 1885, 585) concluded that the inorganic base of the same consisted of alumina and lime in the same relative proportion, namely, $\text{Al}_2\text{O}_3 : 2 \text{CaO}$, as Kopp found in the mordant for Turkey red. The author has analysed a sample of "carmine nacarat" by the method described by Liebermann, for the purpose of ascertaining whether the above relationship obtains in all cases, with the results appended, Liebermann's results being given for comparison:—

	Liebermann.	Lafar.
	Per Cent.	Per Cent.
Moisture	17	15.50
Ash	7	6.87
Nitrogenous matter	20	23.26
Colouring matter (by difference)	56	54.37

or calculated on the dry substance:—

	Liebermann.	Lafar.
	Per Cent.	Per Cent.
Ash	8.1	8.14
Nitrogenous matter	24.7	27.6
Colouring matter	67.2	64.24

The moisture was determined by drying at 110°, the whole of it not being removed at a lower temperature. At this temperature the carmine lost much of its brilliancy, which was not recovered even on long exposure to an atmosphere saturated with moisture. The percentage of nitrogen found was 3.49, which, on the assumption that it is all contained in the nitrogenous matter accompanying the colouring matter proper, corresponds to 23.26 per cent. of that substance. The agreement in the two results as regards the content in inorganic matter is notable; the composition of the ash was also found to be practically the same as Liebermann stated, namely:—

	Liebermann.	Lafar.
	Per Cent.	Per Cent.
CaO	Trace	0.35
SnO_2	0.67	0.14
Al_2O_3	43.09	40.18
Fe_2O_3	Trace	Trace
CuO	44.85	44.20
MgO	1.02	0.61
Na_2O	3.23	5.49
K_2O	3.56	3.20
P_2O_5	3.20	2.71
SiO_2	Trace	0.60
CO_2 (by difference)	2.31

Calculating the magnesia found into its equivalent of lime, and adding this to the percentages of lime found, the percentages of lime and alumina are respectively:—

	Lebermann's.	Lehar.
	Per Cent.	Per Cent.
Al ₂ O ₃	47.00	47.48
CaO + MgO + CaO	52.28	47.05

in the formula of the base, calculated for Al₂O₃ : (CaO + MgO) as, from Lebermann's results, 1 : 1.072, and, from the authors', 1 : 2.044. The results obtained, therefore, completely support Lebermann's hypothesis.

These results, the author points out, would prove that the hitherto published methods of preparation of carmine are purely empirical.—E.R.

New Mode of Formation of Indazole Derivatives.—O. N. Witt, F. Noetting, and E. Grandmougin. Bull. Soc. Ind. Mulhouse, 1891, 70—81.

p-NITRO-*o*-CRESOL (CH₃—OH·NO₂, 1:2:4), melting at 106—108°, is formed almost quantitatively when a solution of the calculated amount of sodium nitrite is added to a boiling solution of *p*-nitro-*o*-toluidine (CH₃—NH₂·NO₂, 1:2:4) in dilute sulphuric or hydrochloric acid. When, however, this base is diazotised in the ordinary way, and the solution of the resultant diazo-compound heated gradually to the boil, there is obtained, along with nitro-*o*-cresol, another substance, which has been recognised as nitro-indazole.

Nitro-indazole—

was obtained, as above indicated, by slowly heating to the boil an aqueous solution of *o*-diazot-*p*-nitrofluene sulphate, only a faint evolution of nitrogen taking place. The solution, whilst still hot, is filtered to separate a little tarry matter. The filtrate, as it cools, deposits the products of the reaction in the form of oily drops, which collect together and soon solidify to a mass of yellow needles. After filtering off and washing, these crystals melt, as a rule, at 12°, and consist of about equal parts of nitro-indazole and nitro-*o*-cresol. It was not found possible, by variation of the manner of decomposition of the diazo salt, to effect any material increase in the yield of nitro-indazole. The two compounds were separated by repeated crystallisation from water, in which nitro-*o*-cresol is the more soluble. Five such crystallisations yielded nitro-indazole in a pure condition. It crystallises in white, silky, lustrous needles, melting at 18°. Small quantities of it are unchanged; larger quantities decompose with explosive violence. It is soluble in alcohol, acetic acid, xylene, &c. It dissolves easily in solutions of the alkalis, forming salts of a fine red colour. The potassium salt is only moderately soluble, and crystallises in orange-red needles.

Methylnitro-indazole—

is obtained by methylation of nitro-indazole with methyl iodide and a minimum amount of potash. It crystallises from benzene in long, flat, yellow needles, which melt at 159°, and sublime, without decomposition, at a higher temperature. It is very feebly soluble in water. When boiled with excess of alcoholic potash it is converted into an azoxy derivative; hence the necessity for avoiding an excess of potash in its preparation.

Acetylnitro-indazole—

forms colourless needles, melting at 139—140°, and volatile without decomposition. This compound is quite insoluble in water. It is readily saponified by alkalis.

Bromonitro-indazole—

was prepared by the action of an excess of bromine water on nitro-indazole, precipitated by acid from its alkaline solution, and, therefore, in a fine state of division. The product, after being washed, was crystallised from benzene. It forms small yellow prisms, which dissolve in hot aqueous soda, yielding, on cooling, splendid needles of the sodium salt.

Oxidation of Nitro-indazole.—Nitro-indazole is not attacked by boiling nitric acid; chromic acid solution decomposes it with formation of nitrogen, carbon dioxide, and a little tar; prolonged boiling with potassium bichromate and dilute sulphuric acid causes the production, in addition to the gases named, of a small quantity of a yellow powder. This powder dissolves very freely in the ordinary solvents; it appears to be a weak base. Its analysis shows it to contain 19.06 per cent. of nitrogen. Sufficient of it was not obtained for further examination.

The behaviour on oxidation of nitro-indazole proves that it does not contain a methyl group.

Reduction of Nitro-indazole.—This was effected by adding 5 grms. of nitroindazole to a hydrochloric acid solution of 30 grms. of stannous chloride. The nitro-compound dissolves immediately with disengagement of heat, and the stannic double-salt separates in colourless needles. On the removal, by precipitation, of the tin, the hydrochloride of amido-indazole—

is obtained in deliquescent, colourless needles. The free base is best obtained by the reduction of nitro-indazole with alcoholic ammonium sulphide. By repeated crystallisation from water it is obtained pure, either in the form of anhydrous white needles or colourless plates, containing a molecule of water of crystallisation. The needles melt at 270°, but sublime at a lower temperature. Amido-indazole is sparingly soluble in alcohol and cold water, freely so in hot water. It is dibasic; thus, if suspended in water and treated with acid, complete solution only takes place when two molecules of a monobasic acid have been added to one of the base. That it contains only one amido group is shown by the bluing of iodised starch-paper, on the addition to a solution of it of an amount of sodium nitrite slightly in excess of that required to diazotise one amido-group.

Hydroxy-indazole—

is obtained by boiling the salts of diazo-indazole with water, and extracting with ether. After evaporation of the ether, it is left in the form of beautiful red needles, which, on purification by sublimation, suddenly become white. Crystallised from water, it melts at 215—216°. It possesses a quinine-like smell.

Indazole—

was prepared from amido-indazole both by Friedländer's (this Journal, 1889, 50) and the ethyl nitrite methods. Prepared by the first method, the product melted at 146—147°; by the second, at 145—146°. Fischer and Kuzel give the melting point as 146·5°. The product was found to be identical in all respects with the indazole of Fischer and Kuzel.

The authors, further, diazotised *o*-toluidine and boiled the product with water to ascertain whether any indazole were formed in this manner, but found no trace of that substance. Their attempt also to prepare a homologue of nitro-indazole from *p*-nitro-*m*-xylydine ($\text{CH}_3 : \text{NH}_2 : \text{NO}_2 : \text{CH}_3 = 1 : 2 : 4 : 5$) was unsuccessful, the corresponding nitroxenole alone being formed.—E. B.

PATENTS.

Colouring Matters Obtainable by the Combination of Tetrazoditoyl- or Tetrazodixylyl-salts with Alpha- and Beta-naphthylamine or their Mono- and Disulpho-acids, and Process for the Manufacture of the same. H. J. Haddan, London. From the "Farbenfabriken vorm. F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 3803, March 24, 1885. Amended March 27, 1890. (Second Edition.) 6d.

THE original specification has already been abstracted (this Journal, 1886, 36). In the present amendment the use of tetrazodixylyl is disclaimed and also the use of the α -mono-sulphonic acid and the γ -disulphonic acid of β -naphthylamine. The weight of β -naphthylamine-6-sulphonic acid which combines with the tetrazoditoyl chloride from 100 kilos. of toluidine sulphate is amended to 115 kilos. instead of 112 kilos. in the original specification, and there are besides some corrections of clerical errors.—T. A. L.

The Manufacture and Production of a New Compound and of Artificial Indigo from Phenyl-glycocol, or Analogues, Compounds, or Derivatives thereof. J. Y. Johnson, London. From the "Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 8726, June 5, 1890. 6d.

THIS process for the production of artificial indigo consists in fusing phenyl-glycocoline or one of its homologues with twice its weight of caustic potash at a temperature of about 300° C. in a closed vessel. The end of the reaction is shown by the melt assuming a deep orange colour, or tests may be taken at intervals from the melt, dissolved in water, and air blown through the solution. When no increase can be observed in the amount of precipitate formed, the reaction is complete. The whole melt is then dissolved in water and air passed through the solution so long as a precipitate is formed. The indigo thus produced is filtered off, washed successively with water, hydrochloric acid, and alcohol, and finally dried. The phenyl-glycocoline used is prepared by boiling for about 4 to 6 hours two molecular proportions of aniline with one molecular proportion of monochloroacetic acid and twice the whole quantity of water. The phenyl-glycocoline separates out on cooling, and when dry is sufficiently pure to use for the process. In place of aniline, its homologues *o*-toluidine and *m*-xylydine, and also methyl-aniline and its homologues may be employed. The products thus produced in their turn are used for the formation of homologues of indigo. A sulphonated indigo which can be employed like indigo carmine is produced by adding phenyl-glycocoline to twice its weight of fuming sulphuric acid containing about 30 per cent. of SO_3 , the temperature not being allowed to rise above 40° C. When dissolved, a stream of moist air is passed through the solution until the colour becomes no deeper. The whole is then poured into 10 times its weight of water, salted out, filter-pressed, and dried.

—T. A. L.

The Production of New Azo-Colouring Matters. Brooke, Simpson, and Spiller, Limited, and A. G. Green, London. Eng. Pat. 10,448, July 5, 1890. 4d.

DIRECT-DYEING cotton colouring matters are obtained by combining diazotised primuline with *m*-diamines, azo-derivatives of *m*-diamines, such as Bismarck brown and

chrysoidine, or with α -naphthylamine, and in this latter case re-diazotising the product and combining it with a phenol or amine, but preferably with a *m*-diamine. The order of combination may, in many of these cases, be reversed, giving the same result, viz., the *m*-diamine may be diazotised and combined with primuline. A colouring matter dyeing cotton and wool red from an alkaline bath is produced by dissolving 25 lb. of primuline and 3·5 lb. of sodium nitrite in 30 galls. of water, adding 1·5 galls. of hydrochloric acid of 33 per cent. to the cold solution. A solution of toluylene diamine, equivalent to 10 lb. of *m*-binitrotoluene, and 20 lb. of sodium acetate is then run into the diazotised primuline. After the combination is complete the colour is dissolved up by the addition of caustic soda, precipitated with salt, filter-pressed, and dried.

—T. A. L.

The Manufacture and Production of Artificial Indigo and of a New Material suitable for Use therein. J. Y. Johnson, London. From "The Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 10,509, July 7, 1890. 6d.

AN extension of Eng. Pat. 8726 *o.* 1890 (see above), describing the preparation of artificial indigo from phenyl-glycocoline *o*-carboxylic acid obtained by condensing aniline-*o*-carboxylic acid (anthranilic acid) with monochloroacetic acid. About 25 kilos. of anthranilic acid, 20 kilos. of monochloroacetic acid, and 33 kilos. of calcined soda are boiled for several hours with 1,000 litres of water in a vessel fitted with an inverted condenser. After acidifying, crystals of the new acid separate out on cooling, and may be separated in a hydro-extractor. One kilo. of the dry product thus obtained is fused in a closed vessel with 2—4 kilos. of caustic potash at a temperature of about 200° C. The operation is stopped when the orange colour of the melt no longer increases in intensity. After rapidly cooling the melt it is dissolved in about 200 litres of water, filtered and air passed through the solution until no more precipitate separates out. The artificial indigo is then filtered off, washed with water, then hydrochloric acid, and finally with alcohol, after which it is dried.—T. A. L.

Production of Novel Colouring Matters for Wool Dyeing and Printing. O. Imray, London. From the "Farbwerke vormals Meister, Lucius, und Brüning," Hoechst-on-the-Maine, Germany. Eng. Pat. 10,802, July 11, 1890. 6d.

AN extension of Eng. Pat. 4577 of 1890 (this Journal, 1891, 249). The sulphonic acids there described (obtained by the action of nitrosodimethylaniline hydrochloride on β -naphthol sulphonic acid) when heated with aniline, and its homologues, or with various other bases in presence of water and soda-lye form sulphonic acids which are valuable colouring matters.—T. A. L.

Manufacture of Azo-Colouring Matters derived from Azogammins. J. Imray, London. From "La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis," Paris, France. Eng. Pat. 11,548, July 23, 1890. 6d.

AN extension of Eng. Pat. 5736 of 1890 (this Journal, 1891, 358) describing the preparation of yellow and orange-yellow colouring matters for mordanted wool, giving shades which are fast to light, air, and fulling. The process consists in combining diazotised *m*-nitraniline or one of its homologues with salicylic acid or with one of the cresotic acids, and reducing the products thus obtained in an alkaline solution with glucose as described in the previous patent.—T. A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

Asbestos Discovery in Victoria. Adelaide Advertiser, May 15, 1891.

THE locality of the discovery is Red Hill, about nine miles easterly from Broken Hill, in the Rockwell paddock, where for a long time past R. Hunsperger has been prospecting on the side of a hill, in which asbestiform rock was known to exist, and lately he struck a large vein of true amianthus, as the true Italian variety of this valuable mineral is called. Specimens have been obtained of great length, one being as much as 28 in., and the staple ranges from a striated salmon-tinted variety known as pierolite from near the surface, to a beautiful snow-white flossy fibre of a considerable length and good tensile strength, taken from the shallow depth of 20 ft., while the material is now improving rapidly every foot. On the top of the hill veins of coarse crysotile, the Canadian variety, are found in a ferruginous gangue of what appears to be chrome iron. Lower down a strong vein has been opened, while to the eastward is the deposit of amianthus, which seems of considerable extent. Stems of green carbonate of copper are plentiful, and both silver and gold in small quantities have been found on the property, a not unfrequent occurrence in asbestos country.

PATENT.

An Improved Apparatus for Testing Wool. E. Jaegermayer and A. Michel, Vienna, Austria. Eng. Pat. 9755, June 24, 1890. 8d.

To estimate the true market value or "rendement" of wool, a sample of it is placed in a cylindrical box of sheet metal, and its weight ascertained by means of a scale beam and sliding weight. Then the wool is compressed by screwing down the cover of the box, the same pressure being used in all cases. To effect this the nut of the screw is connected with a series of levers so weighted as to regulate the force applied. The volume of the compressed wool is then read off a scale, and the patentees are of opinion that the "rendement" of the wool can be calculated from the weight and volume thus indicated.—H. S.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

The Fastness of Dyed Colours to Light and Air. A. Woscher, Zeits. f. angew. Chem. 7, 211-212.

THE fading, or change of shade, of dyed colours, which in most cases takes place on exposure to light and air, is due to one of the following causes:—

1. The action of light alone.
2. That of atmospheric oxygen.
3. That of atmospheric moisture.
4. That of certain acid gases contained in the air, namely, carbon and sulphur dioxides.
5. The volatility of the dyestuffs or colours.
6. Two or more of the above influences acting simultaneously.

Joffe (this Journal, 1888, 679) has shown that by exposure to light alone very few colours are altered, and then only slightly. In the absence of air, some of the most fugitive colouring matters known, such as Cyanine, for example, are unattacked by light; Picric acid, dyed on wool, is reddened.

With dyed goods exposed to the air in the dark, too, the author finds that change of shade or tone takes place exceedingly slowly.

Atmospheric moisture can by itself affect only those colours which are not absolutely fast to washing, the dyes or colours, by the action of moisture, becoming dissolved

out from the interior of the fibre; thus, Crocein scarlet on cotton is loose to washing, and therefore badly withstands exposure to moist air, whereas on wool, on which it is fast, it is unaffected by moisture.

Carbon dioxide and sulphur dioxide directly affect many colours. Certain dyes of the benzidine class, in particular, are very sensitive to the former of these gases. The injurious effects of sulphur dioxide are frequently visible in the more exposed parts, i.e., the folds and selvages, of dyed goods, stored in rooms where coal-gas is burnt. In consequence of this, many firms have either adopted electric lighting or have made arrangements for the thorough ventilation of their store-rooms.

Volatility is a defect seldom or never possessed by dyestuffs in use at the present time.

Under ordinary circumstances, the colours on dyed fabrics are exposed to the combined action of light, atmospheric oxygen, moisture, carbonic acid, and sulphur dioxide. In presence of air and moisture, light encourages an oxidising action, as is seen in the old method of croft-bleaching. The effect of this action varies considerably with different colours, according to their chemical constitution. Colours produced, or partially produced, by oxidation naturally offer more resistance to this oxidising action than others; thus Aniline black, Indigo blue, Paraphenylen blue chromed after dyeing, Benzoazurin treated, after dyeing, with copper sulphate, &c., are very fast. On the other hand, there is a large number of colours not produced by oxidation, which are very fast to light and air, for example, Alizarin red, Alizarin carmine (on wool), Alizarin blue, Crocein scarlet (on wool), Chrysamin, Mikado orange (on cotton), and many others.

The rays of light, which, acting in conjunction with air and moisture, produce the maximum oxidation of dyed colours, are not, as generally supposed, the blue, violet, and ultra-violet, but the red, orange, yellow, and green. Other conditions being equal, the more intense the sunlight, the greater is the fading action or change of colour, the solar heat being also a factor of some importance in this change.

It is difficult on account of the great diversity in chemical nature of the numerous dyes in use, to find a general means of increasing the fastness to light and air of dyed colours, without at the same time modifying their shades or characters. Scheurer (this Journal, 1891, 460) has recently recommended the use of a thickened solution of ammoniacal cupric hydrate for rendering colours fast to light. The results obtained by this method are satisfactory, but the range of colours experimented upon was too limited to warrant Scheurer's conclusions as to the generally beneficial effect of the treatment, especially as there are many colours whose purity of shade is injured thereby. The author also differs from Scheurer as regards the theory of the action of the copper oxide layer. Scheurer attributes the action solely to the power possessed by that layer of intercepting the actinic rays of light, apparently considering that the chemical action of light on the whole range of colours is confined to certain rays. In the author's opinion, on the other hand, ammoniacal copper hydrate, applied in the way Scheurer directs, acts on the cotton-cellulose, producing a superficial water and air-proof film over the fibres, and so robbing the light of its power of acting on the colours.—E. B.

On the Formation of Coloured Lakes. L. Vignon. Compt. Rend. 112, 580-582.

THE author has compared the relative lake-forming power of stannic acid in solution and precipitated meta-stannic acid, the basic colouring matter, safranine, being employed. The first substance gave a lake of a full red colour, whilst the meta-stannic acid had taken up only a faint rose colour after washing with water until free from adhering colouring matter. The author considers that the lake-forming power of the two acid substances may be regarded as equivalent to their relative thermo-chemical energies which in combining with soda are as 32.7 to 2.3 heat units respectively.

See also this Journal, 1890, 774 and 855.—G. H. B.

*Note on the Theory of various Phenomena in Dyeing.*L. Vignon. *Compt. Rend.* **112**, 623.

THE greater ease with which the animal fibres absorb dyes is due simply to the fact that they exhibit in a far stronger degree than the vegetable fibres, acid or basic properties; and seeing that all known soluble dyeing materials, whether natural or artificial, contain either the acid groups OH or NO₂ or the basic NR₂, the absorption of the colour by the fibre becomes a purely chemical phenomenon. The single exceptions to this rule are the tetrazo dyes, which are absorbed by cotton in an alkaline bath without mordants.

—F. H. L.

PATENT.

Improvements in Apparatus for Dyeing Straw Goods and for Similar Purposes. H. H. Lake, London. From E. B. Seaver, Boston, U.S.A. Eng. Pat. 2439, February 10, 1891. 11d.

THIS invention relates to the dyeing of straw goods, and particularly of made-up straw hats. The process of dyeing hitherto generally practised is to dye the braided straw in an open kettle. By the present invention the articles made up to shape are supported on a suitable carrier placed within a closed chamber capable of withstanding considerable internal pressure, and within this the whole of the processes of steaming, dyeing, and drying are carried out without

removal of the goods. Means are provided for admitting steam into the cylinder, for subsequently exhausting the air and condensed water; then admitting the dye-liquor and maintaining it in a state of agitation or ebullition (as may be required); and finally for withdrawing the liquor and drying the material by means of either hot or compressed air. The details of the devices employed for carrying out these processes do not admit of suitable abstraction, and for them the original specification and accompanying drawings must be consulted.—W. E. K.

VII.—ACIDS, ALKALIS, AND SALTS.

Twenty-Seventh Annual Report on Alkali, &c. Works by the Chief Inspector. Proceedings during the Year 1890, presented to the Local Government Board and to the Secretary for Scotland. 1891. 7d.

THE report covers 112 pages.

The following tables show the distribution of the various registered works in England, Ireland, and Wales for the year 1890, and also the kinds of processes under inspection. The number of works in Scotland was 126, including 16 alkali works, giving a total of 1,034 works in the United Kingdom.

There have been no prosecutions during 1890 for exceeding the limit laid down in the Act of the amount of noxious gas emitted, but complaints have been received of nuisances arising from works not registered under the Alkali Act. One notable exception to this freedom from complaint is the new Chance-Claus process, not yet included within the Act, for the recovery of sulphur from tank waste, which has given rise to serious complaint owing to the escape of sulphuretted hydrogen gas. As this process is only recent, its difficulties are only in course of being surmounted, and as it has been widely adopted, complaints have been numerous. Various means for preventing the escape of sulphur gases from this process have been tried, and at the works of the Newcastle Chemical Company the residual gases were effectually cleansed by pumping through layers of tank waste diluted with water and then through ferric oxide, but the method had to be abandoned as the pumps could not be kept in working order. The British Alkali Company in Widnes adopt the plan of burning and sending the residual gases through sulphuric acid chambers. Any loss arising from the dilution of the chamber gases is said to be balanced by the gain of sulphur yielded by the gases. At another works the gases are burned in pyrites kettles and allowed to pass through the salt cake cylinders of the Hargreaves process. In the majority of the works special furnaces have had to be employed for burning the sulphuretted hydrogen to sulphurous acid as a preliminary to sending it away through the chimney of the works. A satisfactory method of dealing with the waste gases from the Chance-Claus process adapted for universal needs has not yet appeared.

The amount of salt manufactured in different districts was

	Tons.
Cheshire	1,148,578
Widnes	268,488
South-Eastern Counties	67,600
Durham	27,000
London	10,730
Scotland	8,478

Total 1,569,874

In 1889 the total amount was 1,750,790 tons, which was less by 12 per cent than that made in 1888. Of the salt produced in the United Kingdom, about one third is exported. Of the remaining two thirds, three fourths are used in the soda industry, leaving one fourth to supply all that is required for domestic use, the saving of provisions for agricultural and all other purposes.

In giving the relative strength of the two rival branches of the soda manufacture in the following table, the salt consumed by the ammonia-soda process is calculated from

the manufacturing equivalent of 1.46 tons of salt to 1 ton of 58° alkali.

SALT DECOMPOSED IN THE LEBLANC AND AMMONIA-SODA PROCESSES (INCLUDING SCOTLAND), IN TONS.

Total	855,020	803,482	797,679

AMOUNT OF SULPHATE OF AMMONIA PRODUCED IN THE UNITED KINGDOM, IN TONS.

	1890.	1889.	1888.
Gas works	102,138	100,711	92,896
Iron works	5,064	6,145	5,280
Scale works	24,730	23,953	22,072
Coke and carbonsing works	2,325	2,795	2,537
Total	134,257	133,604	122,785

The total value of sulphate of ammonia at 12l. per ton was 1,611,084l. Two recent improvements in this manufacture are noticed, namely, the use of sheet copper for constructing the "saturators" in which the ammonia is absorbed by sulphuric acid, and the employment of a steam jet for raising the sulphate of ammonia crystals from the saturator to the drainer, whereby labour is saved and escape of offensive vapours can be avoided by carrying on the work in closed vessels. A method of adapting the "Bee-Hive" coke ovens to a system for recovering the ammonia produced and utilising the gases, introduced by Newton, Chambers, & Co., is described in detail. The yield is 6 to 7 lb. of sulphate of ammonia per ton of coal coked, and the calorific power of the gases is nearly equal to that of blast furnace gases when coke is used for smelting. The economy achieved by the recovery of ammonia from producer gases has received a check in the advanced price of coal in the past year. The combination recently effected amongst alkali makers under the style of the United Alkali Company, is referred to as affording a prospect of still greater efficiency all round in the management of the various works. An extended notice is given of the process of Haddock and Lath for the recovery of sulphur from Leblanc vat waste,

in which the other products obtained are sodium carbonate and bicarbonate, besides calcium carbonate and sulphate.

A process devised by F. Gossage of Widnes is being placed on a manufacturing scale. By it sodium sulphide is formed from sulphate and decomposed by carbonic acid with formation of sodium bicarbonate and evolution of sulphuretted hydrogen which is utilised in any convenient way. No lime is required and no tank waste formed in this process for making alkali.

A third new process for the manufacture of alkali has been patented by Mr. James Simpson, resembling in some respects that of Haddock and Leith, but instead of tank waste it is a mineral phosphate which is submitted to the action of sulphuretted hydrogen, and a highly concentrated calcium phosphate is produced.

The report pleads for the inclusion of all chemical works within the Alkali Act so as to enforce a more complete supervision over the escape of noxious gases.

By the adoption of various means and precautions the escape of chlorine from the chambers used in the manufacture of bleaching powder is kept under close control, and complaints are now but rarely heard. An improvement in the working of the Deacon process has been devised by Mr. Hasenclever, who adds sulphuric acid to the hydrochloric acid of the Leblanc process and blows air through the mixture. This carries away strong hydrochloric acid gas mixed with air, in the proportions suited to their mutual reaction in the Deacon decomposer, leaving much of the water of the hydrochloric acid combined with the sulphuric acid. This acid, thus somewhat diluted can be used conveniently in the Leblanc decomposing pans for action on the salt, and the hydrochloric acid there generated, being more hydrated than hitherto, will need less water in the condensing towers.

The method of producing chlorine introduced by Weldon in connexion with Pechiney, of Salindres, in France, has been adopted by Albright and Wilson at Oldbury.

During the past year continued progress has been made in the adoption of means for diminishing the discharge of black smoke from factory chimneys, and an extensive movement has been organised in several large towns of the United Kingdom for ascertaining the relative merits of mechanical stokers and other smoke-preventing appliances. This work was under the superintendence of Mr. E. W. Parnell, and is now in the hands of Professor A. B. W. Kennedy. It is expected that the outcome of this inquiry will afford information of the highest value to coal consumers and engineers, and to the country at large. The evil which presses most in London and other residential cities is the aggregation of smoke coming from the multitude of house fires, and it is suggested that the remedy for this will probably be found in superseding the use of the open fire by a central stove for supplying warm air for distribution through the building.

The systematic testing of chimney gases in salt works has caused greater care to be exercised in stopping or preventing leakages from salt pans, by which the generation of acid gases has been lessened, and the effect has been beneficial on the vegetation of the neighbourhood.

A mass of detailed information is given in the separate reports of the inspectors for the various districts which cannot be usefully abstracted. In the separate report for Scotland, the following lists are given to show the extent of the manufactures under the inspection provided by the Alkali Act:—

NUMBER OF SEPARATE PROCESSES.

Alkali.....	12
Muriatic acid.....	3

In these there have been the following quantities of material employed or manufactured during the year 1890:—

	Tons.
Salt decomposed.....	34,985
Alkali works.....	5,916
Copper works.....	40,631
Pyrites burned.....	78,890
Sulphur burned.....	3,005
Bones and phosphates used in chemical manure works.....	47,753
Bleaching powder made.....	8,826
Sulphate of ammonia made.....	39,689
Shale.....	24,730
Iron works.....	4,564
Salt manufactured.....	8,478
Nitric acid made.....	3,230

—G. H. B.

Inspection of Chemical Works.

IN the discussion on the Local Government Board vote, in the House of Commons, on Wednesday, July 15th, Mr. Brimmer, M.P. for Northwich, said:—"Then there is another matter which, I think, comes under this vote,—the inspector of alkali works. The law at present is in a very anomalous condition. There are a number of manufactories in the country where the business comes under the designation of alkali works. These works carry on operations on a large scale, and are prevented, under the Act, from the discharge of noxious vapours; but, strange to say, in other works, where they use the products made in the larger manufactories, the Act does not apply. In point of fact there are smaller factories using the products of the larger works, and discharging fumes which do quite as much mischief as those which are evolved from alkali works. Oddly enough, if the inspector can induce the owners of these works to consume these noxious gases instead of turning them out into the air, then the works come under the Act. Those who carry on their work in the most wasteful and harmful fashion are not watched; but as soon as a man ceases doing mischief to his neighbours, then he comes under the watchful eye of the Local Government Board inspector. If the right hon. gentleman (Mr. Ritchie) will consult with the officials of his department, he will, I have no doubt, find that they are entirely at one with me in this matter, and he may be assured an amendment of the law will have the hearty co-operation of the manufacturers who do come under the Act. So far as the sanitary authorities who understand this matter—more especially in London, where the mischief is rife—are concerned, he may rely upon their support too. I hope the right hon. gentleman (Mr. Ritchie) will consider the representation made to him on this subject, and endeavour to put the law into a condition consistent with common sense."

Mr. Ritchie: "I have to say that the matter has been under our consideration, and a Bill to amend the Alkali Acts has been prepared, and I believe it would meet the views of the hon. gentleman; but there has been no opportunity of introducing it this session. I hope the Alkali Acts will be so extended as to embrace the offending factories mentioned by the hon. member, with regard to which I am quite at one with him."

On some Constants of Ammonia. H. von Strombeck. Reprint from J. Franklin Inst. 1890 and 1891.

IN calculating the dimensions of a refrigerating machine it is necessary to know the exact value of the latent heat of evaporation of the liquid used. When the heat of evaporation of ammonia was first determined, it was found to be about 500 French or 900 English thermal units, and many designers still claim that these figures are correct, although it was afterwards shown that the ammonia used in the determination referred to contained a good deal of water. H. V. Regnault afterwards made tests with ammonia free from moisture, and found the heat of evaporation to be

291.2 French thermal units. This and other constants of ammonia have been redetermined with great care by the author in the laboratory of the De la Vergne Refrigerating Machine Co. with the following results:—

I. The *specific heat* of liquid ammonia was measured by placing about 128 grms. of it in a steel cylinder, which was heated to about 62° C. in vapour of boiling methyl alcohol. This was then introduced into a calorimeter containing about a litre of water. The mean value of the specific heat was found to be 1.22876. To make sure that this surprising result was not due to any experimental error, the author filled the steel cylinder with water, and determined its specific heat. The result came out very close to one, namely, 0.99302.

II. The *total heat* of ammonia was measured by allowing liquid ammonia contained in a small tank to evaporate gradually, the gas escaping slowly through vessels divided into small chambers arranged spirally, the whole being surrounded by water contained in a large calorimeter. In the calculation, the value above obtained for the specific heat was used instead of the value (0.799) which Regnault supposed to be correct. The total heat was found to be 313.7 thermal units (being the sum of 292.4 units = heat of evaporation, and 21.3 units = what the author calls "heat of liquid.")

III. *Heat of Absorption of Ammonia*.—The gas was developed from liquid ammonia contained in the tank A B in the figure. This was placed in the larger tank C D filled

APPARATUS FOR THE DETERMINATION OF THE HEAT OF ABSORPTION OF AMMONIA.

with water, so as to make the evolution of gas as constant as possible. The gas was passed through the low stratum of mercury contained in the tube E F, and its velocity could further be controlled by the stop-cock Z. By passing slowly through the glass coils G H lying in the tank I K, the gas was brought to a constant temperature before entering the absorption tank N O P Q. The pipe R S dips into a small glass tube filled with mercury, the object of which is to prevent the water from rushing up in this pipe after coming into contact with the ammonia. The heat of absorption per unit was found to be 505.3 thermal units.

IV. *Heat of Combination of Liquid Ammonia with Water*. For details of this difficult determination, the original paper must be referred to. According to the equivalents of NH_3 , H_2O , 17 grms. of the former combine with 18 grms. of the latter to form 35 grms. of $\text{NH}_4(\text{OH})$. Thus, from a theoretical point of view, it might be best to take the ammonia and water in the proportion of 17 to 18. But for technical reasons it was found preferable to use a larger amount of water, and in the tests made the proportion of ammonia to water was only 8 to 18. Under these conditions the heat of combination (per unit mass of ammonia) was found to be 198.4 thermal units. D. E. J.

Condensation of Nitric Acid. O. Guttman. Zeits. f. angew. Chem. 1891, 238-239.

THE results shown in the table (see next page) were obtained with a double battery of the author's nitric acid condensers (this Journal, 1890, 862), kept in almost uninterrupted working for upwards of two months. The acid manufactured had the concentration of monohydrate, and contained 1-2 per cent. of lower oxides, the weaker tower-acid (specific gravity 1.3-1.4) not being collected, but in factories where the latter is of value, nearly the whole of that quantity shown under "loss" can be recovered. The mean loss of 7 per cent. shown in the table is accounted

for by the following: (a.) The acid retained by the bisulphate; (b.) The lower oxides formed; (c.) The tower-acid; (d.) The portion escaping in the flue. Without the Lunge-Rohrmann tower it is found impossible so to regulate the firing that no portion of acid is uncondensed in the flue; it is seen, however, that in spite of the increased loss of 4.5 per cent. the percentage of lower oxides is only slightly augmented. Rohrmann's earthenware pipes, 8 mm. in thickness, are now used; these are capable of withstanding a higher temperature and facilitate condensation. It has not been found desirable to shorten the time for distilling one charge to less than 11-12 hours, and as a simple control the firing is regulated so that the last pipe remains cold while the one before it is warm. After driving off the lower oxides the acid thus obtained may be used as chemically pure.—A. R. L.

The Preparation and Reactions of Mercury Ammonium Chlorides. G. André. Compt. Rend. 112, 859-861. (Compare this Journal, 1889, 915, 916; 1890, 647).

A SOLUTION prepared by boiling yellow mercuric oxide with a solution of ammonium chloride deposits on cooling a small quantity of crystalline mercurio-diammonium chloride. The mother-liquor from these crystals when treated with an excess of ammonia yields a white curdy precipitate, consisting of a mixture of mercurio-diammonium chloride and mercurio-ammonium chloride, $\text{HgCl}_2 \cdot 2\text{NH}_3 + \text{HgClNH}_2$. Long washing further decomposes this precipitate into a mixture of mercurio-ammonium chloride and oxy-dimercurio-ammonium chloride, $\text{NH}_2(\text{Hg}_2\text{O})\text{Cl}$; whilst extremely prolonged washing results in the production of the latter body alone. When the curdy precipitate mentioned above is heated in a sealed tube to 200° C. with an excess of ammonia, the liquid on cooling deposits mercurio-diammonium chloride. This well-known substance may be prepared in several other ways. A solution of yellow mercuric oxide in

Each charge consisted of 12 cwt. of nitrate and 13 cwt. of sulphuric acid. The tower acid was not taken into account; all other acid was collected in the same receiver.	Analysis of					Employed

ammonium chloride is treated in the cold with ammonia until the precipitate first formed just re-dissolves. The solution is allowed to stand for several weeks over quicklime, when it will yield splendid crystals of the diammonium chloride. The salt may also be obtained by adding the mercurial solution to the ammonia; or again, a current of ammonia may be passed into the solution of yellow mercuric oxide. The mother-liquor from the mercurio-diammonium chloride when largely diluted with water yields a white precipitate, which when washed and dried at 100° C. has the composition of oxy-dimercurammonium chloride. Its formation may be represented by the following equations:—

When a solution of mercuric chloride is added to a mixture of ammonia and ammonium chloride in the cold a curdy precipitate is formed having the composition HgCl_2NH_3 . It is also formed by adding the mercuric chloride in excess to the boiling solution of the other reagents. Washed with cold water the curdy precipitate is decomposed thus—

—H. T. P.

Two New Forms of Sulphur. Engel. Compt. Rend. **112**, 866—868.

THE author describes two new modifications of sulphur, one of which is crystalline and the other amorphous. The first variety is prepared by adding two volumes of strong hydrochloric acid cooled to 10° C. to one volume of a saturated solution of sodium thio-sulphate. The liquid, which must be rapidly filtered to separate the precipitated salt, gradually turns yellow, and sulphur dioxide is given off. When the colour has become very deep and a precipitate begins to form the liquid is agitated with an equal volume of chloroform. The chloroform solution on evaporation yields crystals of sulphur which differ entirely from octahedral sulphur. They have a density of 2'135 and are

orange-yellow in colour. The crystals are at first transparent; but after 3—4 hours, they begin to alter, increase in volume, and pass into the insoluble modification of sulphur. The crystals melt below 100° C., and are converted into a variety of sulphur resembling that obtained from thio-sulphates, i.e., it is partially insoluble in carbon disulphide.

When a mixture of hydrochloric acid and sodium thio-sulphate is allowed to stand, a precipitate of sulphur separates, which soon becomes flocculent. In this state it is entirely soluble in water. The solution is yellow and rapidly decomposes, ordinary thio-sulphate sulphur being precipitated. The change from soluble to insoluble sulphur is not accompanied by any evolution of sulphuretted hydrogen, proving that the above flocculent precipitate does not consist of a polysulphide of hydrogen.—H. T. P.

Improved Method and Apparatus for Concentrating Sulphuric Acid. C. S. Négrier, Périgueux, France. Eng. Pat. 4171, March 17, 1890 8d.

IN the space above a range of burners a chamber is partitioned off, the floor of which is an inclined plane made of iron plates, in which are basin-like depressions. Into these, are set vessels of porcelain or glass, which are filled with the sulphuric acid to be concentrated. The acid flows in a slow stream from one vessel to another, the depressions being arranged so that the lip of one vessel protrudes just over the vessel next below it on the inclined plane. The acid is heated and concentrated by the heat from the burner-gases below the inclined plane. The water and acid vapours rising from the sulphuric acid are drawn off into a leaden receiver, and from there into a second

receiver which unites the products from several systems, and, like the first receiver, is intended for cooling the vapours, which are then carried into the chief lead chamber by means of a carefully regulated injector (See also this Journal, 1891, 46.)—H. S. P.

Improvements in Apparatus for Producing Carbonic Acid and similar Gases.—H. H. Lake, London. From "La Société Anonyme de la Chimie," Lyon, France. Eng. Pat. 4473, March 21, 1890. 8d.

THE apparatus described is for making carbonic acid gas by the action of sulphuric acid upon cakes or blocks of sodium bicarbonate, but it is applicable to the generation of other gases when they are obtained by the action of a liquid upon a solid. The arrangement is automatic in its working. It consists of an outer metallic receptacle or casing, which can be closed hermetically at the top by a cap, which is also fitted with a safety valve and a pressure gauge. There is a stopcock in the upper part of the side of the vessel for drawing off the evolved gas. An opening in the bottom of the casing admits the upper end of a metal rod, which passes down through the inside of an india-rubber tube, and at its bottom end rests upon a metallic cap, which closes, and is fixed to the bottom end of the india-rubber tube. The tube is surrounded by a helical wire, which prevents it expanding laterally; and any increase of the pressure of the gas inside the casing thus causes the tube to lengthen. The lengthening or contraction of the tube raises or lowers the rod moving within it. An arrangement attached to the metal cap at the lower end of the tube allows of the attachment of a lever arm upon which is hung a weight, so that the pressure required to lengthen the tube to a given degree may be regulated by adjusting the weight.

Within the casing and resting upon the upper end of the rod, which just protrudes into the bottom of the casing, is placed a glass vessel which holds sulphuric acid diluted to the proper degree, and within this glass vessel, and in its upper part, is suspended a shorter glass or enamelled porcelain vessel which holds the blocks of bicarbonate of soda. The bottom of this inner vessel is perforated. By moving the lever, the rod below the vessel containing sulphuric acid is raised, and the vessel itself is thus raised and the acid enters through the perforations in the bottom of the vessel holding the bicarbonate of soda, and, acting upon this substance, generates carbonic acid, which is drawn off at the stopcock as required. When the stopcock is closed, the pressure of the gas confined within the apparatus lengthens the india-rubber tube, allowing the rod without it to fall, and lowering the vessel holding sulphuric acid so that the acid is no longer in contact with the bicarbonate of soda. On reopening the stopcock, the pressure is relaxed and the acid-containing vessel again is raised by the contraction of the india-rubber tube and the pressure of the lever arm. One of the advantages of the apparatus is that the acid and gas do not come into contact with lead, as is the case with apparatus in which a leaden receptacle is used to hold the acid.—H. S. P.

Improvements in the Manufacture of Nitrates of Ammonium and of Resulting By-product.—C. V. Burghardt, Manchester. Eng. Pat. 5442, April 10, 1890. 6d.

THE patent relates to improvements in the inventor's patent (Eng. Pat. 8841 of 1889, this Journal, 1890, 620), by which he produced ammonium nitrate by the action of a solution of ammonium sulphate upon a solution of lead nitrate, lead sulphate being obtained as a by-product. In the present patent he uses one of the carbonate salts of ammonium instead of ammonium sulphate, and obtains lead carbonate as a by-product, this salt being more valuable in its crude state and more readily converted into valuable lead compounds than lead sulphate. As a modification of the process, he treats the lead nitrate solution with a solution of ammonia, or with gaseous ammonia, which produces a precipitate of white hydrated lead oxide. This precipitate is filtered off and washed, and is very suitable for conversion into chrome yellows. The filtered liquor

from the lead hydrate precipitate contains ammonium nitrate and some lead oxide in solution. The dissolved lead is precipitated with a solution of ammonium carbonate, and the precipitate of lead carbonate filtered off. The purified solution of ammonium nitrate is then concentrated and the ammonium nitrate recovered by crystallisation.—H. S. P.

Improvements in connexion with Obtaining Chlorine, and in Utilising Calcium Chloride and other By-products.—A. Campbell, Upton Park, and W. Boyd, Glasgow. Eng. Pat. 5571, April 12, 1890. 6d.

WITH the calcium chloride which occurs as a by-product in the various processes for manufacturing chlorine from salt, already patented by the inventors in 1888 and 1889 (this Journal, 1889, 706, 983, 508), and also the calcium chloride obtained as a by-product in any other manufacturing process, as for instance, in the ammonia-soda process, the inventors propose to mix a solution of sodium sulphate, which has been first neutralised with an alkali or alkaline earth, allowed to settle and separated from the precipitated matters. The reaction that takes place is accelerated by heat and results in a precipitate of very pure calcium sulphate and a solution of common salt. The calcium sulphate is then separated, washed, and dried in any suitable way, and the solution of salt is concentrated and used like the original salt for making chlorine.—H. S. P.

A Process and Apparatus for the Manufacture of Ammonia.—H. Baudouin and P. Escarpit, Paris, France. Eng. Pat. 5247, May 9, 1890. 8d.

CARBON, nascent hydrogen, and sodium nitrate react with each other under certain conditions, with formation of ammonia and sodium carbonate. To obtain such a result the following materials are used: 125 parts of hydrocarbons, with coal to suit requirements, and 100 parts of nitre; the decomposition is best performed in a closed vessel, at a temperature of from 800—900; the coal used should be perfectly dry.

Another mixture consists of 45 parts of naphthalene and 100 parts of nitre, heated in a retort-shaped apparatus to nascent red heat. "Naphthalene at this temperature decomposes into carbon and hydrogen, which latter acting in its nascent state upon the nitrate is in its turn decomposed." Ammonia and carbonic acid are generated, and ultimately ammonia, ammonium carbonate and sodium carbonate are obtained. The inventors expect to produce from the above quantities: 18 parts of ammonia gas, 175—185 parts of sodium carbonate with 10 equivalents of water, and in the first case also 50 parts of coke and 5—7 of heavy oils.

In carrying out the process the mixed materials are charged by means of a screw-conveyor from a hopper into one end of an inclined cast-iron retort, in which a pitch chain is working. The sodium carbonate and coke are delivered at the opposite end into a receiver; the escaping gases are first passed in a receiver, in which the heavy oils condense, and then washed with milk of lime to retain the carbonic acid contained in the ammonia.—H. A.

Improvements in Apparatus for Use in the Manufacture of Bicarbonate of Soda by the Ammonia-Soda Process.—J. Vivian, St. Bees, and G. Bell, Wavertree. Eng. Pat. 5527, May 14, 1890. 8d.

THE improvement consists mainly in the cooling of the carbonating vessels and connexions by means of brine, which is afterwards introduced in the process.

The apparatus consists of, say, three carbonators, a separator, a wash-tower, and a brine storage tank, all these parts being arranged vertically, one above the other. Two of the carbonators have conical ends, and are provided with a cylindrical jacket, the upper extension of which forms the sides of the third carbonator, the bottom being formed by the top of the second carbonator. The carbonators are connected by means of pipes, surrounded by brine, for the cooling of the gases, both coolers being attached to the

outer casing of the carbonators. Above the third carbonator, and supported on a suitable framework, is the saturator, which consists of a cylindrical, closed, jacketed vessel, provided with brine-feed and delivery pipes and ammonia gas supply pipes, for both the vessel and the jacket. Above the saturator is a wash-tower with false bottom, and packed with coke; the tower rests on a tray, for collecting and delivering the brine which is fed in from a tank on top of the apparatus.

The carbonators are first charged with ammoniated brine from the saturator. Carbonic acid enters through a valve on the bottom of the lowest carbonator; on leaving this it passes through a cooler in the second, from this through another cooler in the third carbonator; the escaping gases are absorbed in the wash-tower by means of brine, and the inert gases allowed to escape.

The brine is forced in the annular space surrounding the bottom and second carbonator, enters from here the first cooler, ascends the second cooler, and is delivered from here in the brine tank on the top of the tower. The brine is then distributed over the coke in the scrubber, and while descending absorbs the ammonia escaping from the carbonators; it is then delivered in the inner and outer casing of the saturator, where it is treated with ammonia and afterwards charged in the carbonators.

In working the plant, the ammoniated brine is charged in the third carbonator; from here it is run, after a suitable interval, in the second; and after a further interval in the first, where it is completely converted into sodium bicarbonate. The charge is then blown out on a filter through the carbonic acid valve, which for the purpose is provided with a second perforation.—H. A.

A Phosphated Preparation of Common Salt. G. D. Bowie, Guernsey. Eng. Pat. 11,196, July 18, 1890. 4d.

POTASSIUM, sodium, and calcium phosphates in nearly equal proportions are well mixed and finely ground. Common salt is then well ground and incorporated with 3 per cent. of the phosphate mixture to form a prepared table salt.

—G. H. B.

Improvements in the Manufacture of Alkaline Carbonates and By-products, and in Arrangement of Plant therefor. A. G. Haddock, Halewood, and J. Leith, St. Helens. Eng. Pat. 11,296, July 19, 1890. 8d.

ACCORDING to this invention strong solutions of salt-cake and calcium sulphhydrate are mixed to form sodium sulphhydrate and gypsum, the clear solution of the former concentrated and treated with carbonic acid, for conversion into sodium bicarbonate. The sulphuretted hydrogen given off is passed into alkali waste or milk of lime for the preparation of fresh quantities of calcium sulphhydrate, and the remainder used for other purposes.

The salt-cake is dissolved in the wash-waters obtained in the process, to which are preferably added the bicarbonate mother-liquors, whereby any free acid in the salt-cake is neutralised, and iron, lime, and magnesia precipitated. The solution passes through a series of settling tanks into a mixer, where it meets a similarly well settled solution of calcium sulphhydrate; the resulting mass is run out on the bottom on the "pearl hardening filters," which retain the precipitated gypsum, whilst the filtered liquor is drawn into vacuum pans. These deliver the liquor into a mixer, to precipitate the dissolved gypsum with some bicarbonate mother-liquor, and the filtered liquor is further concentrated in vacuum pans until it contains 26·2 per cent. of sodium sulphhydrate, equivalent to 14·5 per cent. of alkali (Na_2O). This solution is pumped into a series of carbonators and subjected to treatment with carbonic acid (free from oxygen), until the alkalinity of the solution decreases to 3·4 per cent. of Na_2O or less. Sulphuretted hydrogen is given off, part of which will have to be passed into a series of carbonators, for the preparation of calcium sulphhydrate, whilst the bicarbonate is run on filters, dried for sale, or finished in a closed furnace to soda ash. The carbonic acid here evolved may be pumped back into the carbonators.

The bicarbonate mother-liquor may be boiled down and treated again with carbonic acid for the separation of more bicarbonate, and the remaining mother-liquor used for dissolving fresh quantities of salt-cake.—H. A.

Improvements in Evaporating Apparatus Specially adapted for the Extraction of Salt from Brine. A. Chapman and S. Vickers, jun., Liverpool. Eng. Pat. 11,529, July 23, 1890. 8d.

THIS apparatus is constructed on the multiple-effect system and is here described as arranged for a quadruple effect. Each pan is fitted with a steam drum as usual, and between the plates forming the top and bottom of the drum is a number of small tubes for the upward flow of the brine, while a large tube, preferably central, is used for the down-flow and is carried some distance below the drum or bottom tube plate. The bottom of each pan is in the form of an inverted cone, having an outlet communicating with a salt receiver below, each of which has a hinged valve door at the bottom. Immediately under each receiver, but not connected with it, is a filter containing gravel, coke, &c., to a depth of 9—12 in., in which is laid a perforated pipe connected with an exhausting pump. These filters may if desired, contain an ordinary salt mould, so that the salt may be drained and moulded at the same time. The last pan of the series is connected with a heater, a condenser, and a vacuum engine. The exhaust steam is conducted to the drum of the first pan as usual, the vapour evolved from the brine going to the drum of the second pan, and so on. The water due to condensation of steam or vapour in each drum, except the last, is conducted to the next pan, preferably by a syphon arrangement of the kind described in Eng. Pat. 2511 of 1888 (A. Chapman) (this Journal, 1889, 128). The feeding arrangement of the brine and other details are fully explained in the specification.—E. S.

Improvements in the Conversion of Hard-Burnt into Soft-Burnt Magnesia. F. M. Lyte, London, and J. G. Tatters, Runcorn. Eng. Pat. 11,545, July 23, 1890. 6d.

By dissolving hard-burnt magnesia in strong aqueous hydrochloric acid and evaporating to dryness, a mixture of, say, 9—10 parts of magnesia and one of magnesium chloride will be formed, and weak hydrochloric acid given off. The mass is then broken up and subjected to a dull red heat, preferably in a current of steam; soft-burnt magnesia will thus be formed, which is suitable for decomposing double ammonium-magnesium-chloride (this Journal, 1890, 1128—1129).

The magnesium chloride present may be eliminated, if necessary, by boiling the soft-burnt mass with water and calcining the residue at a dull red heat.

A modification of the process consists in adding sufficient soft-burnt magnesia to the concentrated acid solution of hard-burnt magnesia, to cause it to "solidify into an oxychloride," which is decomposed as above. The hydrochloric acid gas is condensed, and those fractions which are sufficiently strong used over again for dissolving fresh quantities of hard-burnt magnesia.—H. A.

An Improved Process for Producing Sulphate of Calcium. T. Elliott, Bristol. Eng. Pat. 11,638, July 23, 1890. 4d.

LIQUIDS containing calcium chloride in solution, such as certain waste liquors from alkali manufactures, are treated with dilute sulphuric acid, whereby calcium sulphate is precipitated and recovered by draining off the solution.

—G. H. B.

Improvements in the Method of and Apparatus for obtaining Chemical Products by Utilising Fluoride of Silicon. H. B. Yardley, Leytonstone. Eng. Pat. 12,717, August 14, 1890. 8d.

THE apparatus consists of a lixiviating tank with perforated false bottom, emptying into a series of superimposed funnel-shaped vessels furnished with taps for controlling the flow

of the solutions used. The upper vessel is covered in and arranged for passing gases containing fluoride of silicon through the solution. A salt, such as sodium sulphate, is placed on the perforated tray and covered with water, and the solution is then run into the first vessel for treatment with fluoride of silicon. The products of the reaction are fluosilicate of soda and gelatinous silica, which is washed with water in the series of vessels, the washings being used for preparing fresh solution for treatment. The fluosilicate solution is utilised in any of the usual ways. The precipitated silica also contains fluosilicate, and may be dried and fused with lime for the production of soda.

—G. H. B.

Process and Apparatus for the Simultaneous Manufacture of Phosphorus and of Alkaline Silicates by the Treatment of the Mineral Phosphates of Lime, Alumina, or Bone Ash. L. M. C. Folie-Desjardins, Toulouse, France. Eng. Pat. 13,249, August 22, 1890. 11d.

The process consists in heating a mixture of bone ash or a mineral phosphate of lime or alumina, with an alkaline carbonate or sulphate in a reverberatory furnace or in retorts, silica being added to the mixture when phosphate of alumina is used. The calcined mass is then lixiviated to dissolve out the tribasic phosphate of soda, the solutions evaporated to dryness, and the residue pulverised. The powdered tribasic phosphate is then mixed with silica and carbon and heated in retorts. The reaction results in sodium silicate, carbonic oxide, and phosphorus, and the latter substance is distilled over and collected in a condenser. The specification describes the means to be adopted for recovering the alkali from residues of silico-aluminate of soda that are formed, and drawings of a suitable apparatus for carrying out the process are given.—H. S. P.

New Process for Manufacturing Alkaline or Alkali-earth Cyanides through Atmospheric Nitrogen, and the Application of the same to the Production of Ammonia. R. Baddan, London. From Viscount de Lambilly, Paris, France. Eng. Pat. 16,049, October 9, 1890. 6d.

The method consists in the decomposition of illuminating gas in an atmosphere of nitrogen and in the presence of a mixture of charcoal and alkali.

The nitrogen is prepared by passing air over copper at a red heat, and collecting the nitrogen, thus freed from oxygen, in a gasometer. The copper oxide thus produced is afterwards used for removing the hydrogen from illuminating gas, by passing the gas over the oxide heated to a red heat, and in this way the copper is recovered for using again to remove oxygen from the air. Equal volumes of nitrogen and illuminating gas freed from hydrogen, are then passed over an intimate mixture of powdered charcoal and alkali. The alkali is preferably an oxide or a carbonate of potassium, sodium, barium, or a mixture of these. The mixture of charcoal and alkali is heated in retorts to a high temperature, but a temperature not as high as a white heat. The first result of heating the mixture is to cause an evolution of a considerable quantity of carbon monoxide, and the evolution of this gas prevents the intimate contact of the nitrogen with the "cyanifiable substance." The inventor finds it advisable, therefore, before passing the mixture of nitrogen and illuminating gas into the retorts, to draw off the carbon monoxide, and this gas is used as a fuel for the heating furnace. After the evolution of carbon monoxide has subsided, the nitrogen and illuminating gas are sent into the retorts, and by regulating the speed of outflow these gases are kept at a light pressure in the retorts, which brings them into closer contact with the alkali and facilitates the formation of cyanide. The gases that are then given off, principally consisting of hydrogen and some carbon monoxide, are also used as fuel. Small iron shots may be introduced advantageously among the alkali and charcoal, which, becoming rapidly heated, accelerate the formation of cyanide, and further, it is found that a certain quantity of lime in the retort is useful as it helps to maintain the porosity of the mixture and assists the dissociation of alkaline carbonates.

The decomposition of the cyanide formed is effected by distilling the product from the retorts with water. The cyanide is first wetted with water and, after the lapse of 24 to 48 hours, heat is applied and the ammonia distilled off. The reaction is represented by the equation—

The residue, after the distillation, is dried, and, after a suitable addition of charcoal, may be again used in the cyanurating retorts.—H. S. P.

Improvements in the Manufacture or Production of Chlorine and Caustic Soda, and in Apparatus therefor. J. Greenwood, London. Eng. Pat. 18,990, November 22, 1890. 8d.

The process refers to the manufacture of caustic soda and chlorine by electrolysis a solution of salt. The walls of the electrolysing vessel are made of iron or carbon, in which latter case an outer jacket of electrolytically deposited copper is provided; this vessel forms the cathode. A metal cylinder, coated with carbon, is placed in the centre of the vessel, forming the anode. At a suitable distance between the two poles there is a porous diaphragm, consisting of a number of V-shaped troughs of porcelain or glass, which are built up inside each other, the intermediate space being filled up with asbestos fibre or powdered steatite. It is said that this diaphragm offers less resistance than the usual porous partition and that it prevents the diffusion of the chlorine evolved in the anode section into the caustic soda formed in the cathode section. The vessels may be arranged in series. The brine is supplied from separate tanks to the anode and the cathode of the first vessel, and gravitating along the entire series through the respective sections of the cells, it flows into separate catch-vessels, from whence it is delivered back into the respective tanks; the circulation is maintained till the solutions are sufficiently decomposed. Each electrolysing vessel is sealed with a porcelain cover, provided with a chlorine outlet pipe.

The description is given of another combination, in which a containing vessel of an oblong form is divided by parallel plates (representing the poles) and diaphragms into anode and cathode sections, through which the respective liquors circulate. In this case the cathodes are not coated with carbon.—H. A.

Improvements in Packages for the Packing or Putting-up of Chloride of Lime, Carbonate of Ammonia, and other Volatile and Deliquescent Substances. T. Needham, Huddersfield. Eng. Pat. 19,121, November 25, 1890. 4d.

The packages are made of thin wood, cardboard, brown paper, or other paper, and are of any suitable shape. After shaping, the package is dipped into boiled linseed oil, which permeates and closes the interstices of the material.

—H. S. P.

An Improved Process and Apparatus for obtaining Silicates for Making Glass and the Production of Hydrochloric Acid. W. Walker, London. Eng. Pat. 2019, February 4, 1891. 8d.

See under VIII., page 643.

Improvements in or relating to the Manufacture or Production of Caustic Soda. J. Greenwood, London. Eng. Pat. 2134, February 5, 1891. 4d.

The caustic soda solution obtained by means of electrolysis as described in Eng. Pat. 18,990, of 1890 (see above), is contaminated with a certain amount of undecomposed salt. It is proposed to eliminate this by concentrating the liquid and fishing out the salt. The solution may be further concentrated till it solidifies on cooling, and is then packed in the usual manner.—H. A.

Improvements in the Treatment of Alkali Waste for the Production of Sulphuretted Hydrogen. R. H. Davidson and R. H. Davis, Widnes. Eng. Pat. 8901, June 9, 1891. 4d.

THE inventors find that the presence of soluble and insoluble soda in alkali waste is detrimental to the working of the Chance sulphur-recovery process, as the sulphuretted hydrogen given off from such waste is not of a regular strength and the elimination of the last traces of sulphides is not easily accomplished. These difficulties are due to the formation of sodium sulphhydrate, which is not as easily decomposed by carbonic acid as calcium sulphhydrate. It is proposed to add calcium chloride to the milk of waste, and thus to convert the soda compounds into sodium chloride, with formation of calcium carbonate.—H. A.

(the improved construction of which is a part of the invention), and when the temperature has been raised nearly to the point at which common salt volatilises, superheated steam is passed in through a pipe which first coils several times round the outside of the crucible (the steam being thus superheated), and finally passed nearly to the bottom of the crucible, the steam issuing from a number of perforations in the side of the tube. The operation is continued till no more hydrochloric acid is formed. The pure silicates of soda and lime which remain are mixed with plate glass cullet and are subsequently treated as in the ordinary process of plate glass manufacture.—V. C.

Improvements in the Methods and Appliances for Drying Moist Material, for instance newly-formed Bricks, Pipes, Flays, and such like, by Means of Artificial Heat. G. Weigelin, Stuttgart, Germany. Eng. Pat. 679*, April 20, 1891. 8d.

THE patent relates to the drying of bricks, pottery, and similar materials quickly but without risk of fracture.

The drying chambers are placed on each side of a passage common to the set, with which communicate the furnaces by which the chambers are heated. The chambers are worked systematically, the air that is used for cooling one of a set passing into another chamber and thence to the furnace of a third, the heat from which is utilised for a fourth. Although the system is described with sets of four chambers, any other number suited to the work in hand may be used. The circulation of the products of combustion through the goods to be dried is arranged so as to avoid the mixture of large volumes of air with the hot gases, which would lead to waste of fuel.

It is claimed that the utilisation of the fuel is so complete with this apparatus that the artificial drying of goods such as bricks, generally dried with difficulty in the open air, can be effected economically.—B. B.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

PATENTS.

Improved Means and Appliances for Manufacturing Glass Tubing and for Coupling together such Tubing. D. Rylands, Stairfoot. Eng. Pat. 10,348, July 4, 1890. 8d.

THE invention consists of certain improvements for making and coupling glass tubes so as to form safe and water-tight joints. The tubes may by use of suitable moulds be formed with flanged ends and a screw thread. To join two such tubes a metal union is cut into halves, passed over the screwed end of one tube, and then the two halves are clamped or screwed so that it can be screwed on the threaded end of another glass tube.—V. C.

Improvements in the Manufacture of Glass Tubing. D. Rylands, Shepote, and A. Husselbee, Stairfoot. Eng. Pat. 11,651, July 25, 1890. 8d.

By this invention screw threads are formed on glass tubes so that two pipes furnished with these threads can be joined together by a metal socket or coupling having a screw thread formed on it. By somewhat similar arrangements to those employed in the above, a glass tube can be formed to a polygonal or fluted shape, thereby giving increased strength. To form a screw thread the end of the tube is re-heated in the furnace and the heated end introduced into a mould having a screw thread cut on the inside. Air is then forced down the tube so as to drive the glass into the threads of the mould. The mould carries at one end a box, so that a sort of "burst off" is formed at the end of the thread, which is subsequently removed. The moulds are generally made to open at the sides. The improved mould is an essential part of this invention.—V. C.

An Improved Process and Apparatus for obtaining Silicates for Making Glass and the Production of Hydrochloric Acid. W. Walker, London. Eng. Pat. 2019, February 4, 1891. 8d.

THE advantages of this process are (a), that best quality plate glass can be made from impure sand; (b), that a new use is found for waste calcium chloride; and (c), that the chlorine of the calcium chloride is recovered in the form of hydrochloric acid, which can be condensed and used for making bleaching powder. The process depends on the mutual decomposition (at a temperature somewhat below that at which common salt volatilises) of calcium and sodium chlorides, steam, and silica (sand). The sand is first finely pulverised (preferably wet), washed with hydrochloric acid, dried, and then 60 parts are mixed in a crucible with 36 parts of chloride of calcium and 32 parts of common salt. The crucible is placed in a circular gas-fired regenerative furnace

PATENTS.

Improvements in Concrete to be used in the Construction of Vaults, Roofs, Arches, Floors, and the Like. F. Sang, London. Eng. Pat. 8108, May 23, 1890. 4d.

TUFA sand, which is found as small pellets or granules in the Rhenish provinces, is mixed dry or wet with Portland or other cement, and the concrete formed moulded into any desired shape. A mixture of equal parts is said to be as strong as granite and less than half its weight, but for many purposes a mixture of 1 part of cement to 3—5 of Tufa sand, suffices.

Besides being applicable for ordinary building purposes, the patented material is said to be a good non-conductor of heat, and therefore to be fit for forming the roofs of bakers' ovens and similar uses.—B. B.

Improvements in the Manufacture of Cement and in the Treatment of Articles cast therefrom. O. Prinz, Schwarzenberg, Germany. Eng. Pat. 8549, June 2, 1890. *Id.*

The inventor claims "the employment of gelatinous substances, such as albumen or white of egg, gum, dextrine, starch, vegetable mucos, agar-agar, gelatinous silica, hydrate of alumina, hydrated oxide of iron, and generally all oxides that are voluminous and gelatinous, as an addition to chloride of magnesium solution for the purpose of the production of non-separating and non-swelling sord cement" (*see*, a compound of magnesium oxide with magnesium chloride and water); also, "the treatment of sord cement articles alternately with carbonic acid and with water for the purpose of suppressing the sweating of the cement." *L. G. C.*

Improvements in Apparatus for Use in the Manufacture of Cement, and Improvements connected with the said Manufacture. D. Wilson, Clewer. Eng. Pat. 8919, June 9, 1890. *Id.*

1. The revolving cylinder lined with refractory material, through which the flame and dried and pulverised-lorry, &c., are caused to pass, the displacement of the lining blocks is avoided by the inventor's plan of securing the blocks of one of them by suitable projections inside the cylinder. For the details the specification must be referred to.

— E. G. C.

A New or Improved Cementing Material. A. L. Daguzau, St. Médard, France. Eng. Pat. 8993, June 10, 1890. *Id.*

This material is called by the inventor pyro-cement, and is "a blackish product, which adheres strongly to iron, wood, stone, &c." The following constituents and proportions yield a useful result: "18 to 25 per cent. of gas petroleum or other resinous matters, 75 to 80 per cent. of clay or argillaceous earth and silica, "to 8 per cent. of natural sulphates." *L. G. C.*

An Improved Artificial Marble. H. Ruick, Frankenstein, Germany. Eng. Pat. 5309, March 25, 1891. *Id.*

This composition ("marmafit") contains 2 parts of magnesia, 2 parts of lime and quicklime, 1 part of carbonic acid, $\frac{1}{2}$ part of silicic acid, $\frac{1}{2}$ part of argillaceous earth, and 1 part of magnesium chloride. *L. G. C.*

X.—METALLURGY.

Aluminium. Eng. and Min. Jour. 1891, 280.

A. T. Hirst stated in a lecture before the Boston Society of Arts, that the extravagant claims made concerning the production and properties of aluminium had constituted the chief difficulty in its introduction and extended use. The pure metal is soft and weaker than the commercial variety containing 3 to 4 per cent. of impurity. The tendency of aluminium to become coated with a thin film of oxide on exposure to air gives it a dull appearance and makes it unsuited for table ware. It loses its tensile strength and much of its rigidity at 400 to 500 °F., becomes pasty at 1,000 °F., and melts at 1,500 °F. It does not roll or cast well, and its conductivity for heat and electricity is only about half that of copper, its tensile strength is not greater than that of common cast iron, and only about one third that of structural steel, while its strength in compression is only about one-sixth that of cast iron. A bar of aluminium 1 in. square and 4 ft. 6 in. between its supports deflects 2 in. with a load of 250 lb., while a similar

bar of cast iron requires double the load to give an equal deflection. The modulus of elasticity of cast aluminium is about 11,000,000, being only about one-half that of cast iron and one-third that of steel. Its presence in iron is stated to be deleterious, and it is said not to lower the melting point of steel, statements to the contrary notwithstanding. The theoretical cost of 1 lb. of aluminium as made by the Pittsburgh Company is 20 cents per lb., the items being: 2 lb. of alumina, 6 cents; 1 lb. of carbon electrode, 2 cents; chemicals, carbon dust, and pots, 1 cent; 22 electrical horse-power for one hour (water power being used), 5 cents; labour and superintendence, 3 cents; general expense, interest, and repairs, 2 cents (this amounts to only 19 cents).

Although the value of aluminium has been much over-rated, both it and its alloys have many useful qualities. The difficulty of soldering it is alleged to have been overcome by the use of a special flux (nature not stated). Hard or soft solder, zinc or an alloy of zinc and aluminium are the solders used. The difficulty caused by the softness of aluminium is also said to have been overcome by alloying it "with a few per cent. of hardening metal," or hammering or drop forging.—B. B.

Note on a Volatile Compound of Iron and Carbonic Oxide. L. Mond and F. Quincke. Proc. Chem. Soc. 1891, 100, 117-118.

EXPERIMENTS were described by the authors, which lead them to the conclusion that iron forms a volatile compound with carbonic oxide of the formula $\text{Fe}(\text{CO})_5$, corresponding with the nickel compound already prepared and described by them in conjunction with Langer (this Journal, 1890, 808 and 809). Very finely divided iron—obtained by the reduction with hydrogen of oxalate of iron at a temperature very little over 100°, and allowing it to cool to 80° in hydrogen—when heated in an atmosphere of carbonic oxide yielded a gas burning with a yellow flame. On passing the gas through a heated tube a mirror of iron was formed at between 200° and 350°, whilst at high temperatures black flakes of iron and carbon were deposited. After six weeks' treatment of 12 grms. of the metal, only about 2 grms. of iron were volatilised, and then it was found necessary every five or six hours to interrupt the operation and to re-heat the iron to 100° in hydrogen during about 20 minutes. When passing carbonic oxide at the rate of about 2½ litres per hour, not more than 0.01 gm. of iron was volatilised, corresponding to less than 2 cc. of the compound $\text{Fe}(\text{CO})_5$ in a litre of gas. An analysis of the compound has been made by passing the mixture of gases into mineral oil boiling between 250° and 300°, and heating the solution so obtained to 180°. Iron free from carbon is then deposited and carbonic oxide gas is evolved. The five analyses recorded indicate a ratio of $\text{Fe}:\text{CO}$ varying only from 1:4.03 to 1:4.264.

In the discussion which followed H. E. Armstrong considered that the results given afforded an explanation of the permeability of iron by carbonic oxide at high temperatures as well as of the production of steel by the cementation process. Just, the speaker, imagined, as platinum was permeable by hydrogen and silver by oxygen at high temperatures, so iron was permeable by carbonic oxide, and in each case it might be supposed, because a dissociable volatile compound of the metal with the respective gas was formed.

F. L. Thorpe also referred to the light shed by the experiments quoted upon the manner of producing steel by cementation, and pointed out that in conjunction with L. P. in studying the interaction of nitrogen peroxide and carbonic oxide under the influence of finely-divided platinum, he had observed that platinum caused the separation of carbon from carbonic oxide.

L. Mond said that though aware of the possibility of considering their discovery applicable in the directions indicated, seeing, however, that the compound was only formed at low temperatures, and was unstable, as shown, at a temperature below 180°, they had refrained from discussing such matters.

PATENTS.

Improvements in and Apparatus for the Separation of Gold and Silver from Ores or Materials containing them. W. D. Bohm, Acton. Eng. Pat. 3246, February 28, 1890. 8d.

THE powdered ore or material containing gold or silver is placed in a vessel or vat provided with a perforated false bottom covered with coarse canvas, upon which the pulverised ore is placed, and below which a coil of pipe admits the leaching solution. The leaching solution, previously heated, is forced through the ore by a pump, and then through a filter at the top. The solution is then passed into a second vessel, in which it is treated with the precipitating agent. From this vessel the solution is forced up by a pump through a vessel having a filtering arrangement, such as a porous diaphragm, at the top, so that the solid matter is thereby retained, the liquid passing off to be heated again and to be strengthened by the addition of the necessary further quantity of leaching chemicals, and passed back to the leaching vat for use again.

The pressure under which the liquids are forced up through the leaching vat and precipitant vessel should be at least 18 lb. per square inch. At intervals the solid matter retained by the last-named filtering vessel is passed into a filter press or equivalent apparatus, whereby it is deprived of the greater part of its moisture. The ore which has been leached is then drained of all solution and washed free from the last traces with water, and can then be washed out of the vat with acidulated water and passed over zinc or alloy of zinc with other suitable metal, so that hydrogen is evolved, which reduces any precious metal still remaining in the ore to the metallic state, or to such a state that it is taken up when the ore is passed over mercury. Two leaching vats are, preferably, arranged side by side, so as to be washed alternately.—J. H. C.

An Improved Process of Manufacturing Iron and Steel. A. Turner, Greenock; A. Baird and M. B. Baird, Glasgow. Eng. Pat. 5545, April 12, 1890. 4d.

THE inventors propose to manufacture various grades of iron and steel by mixing ordinary pig iron with the requisite quantity of pure iron obtained by the reduction of a pure ore by means of an electric current. The mixing may be effected either in the furnace or in a ladle, &c.

—S. B. A. A.

Improvements in the Manufacture of Iron and Steel. J. H. Lancaster, New York, U.S.A., and M. R. Conley, Brooklyn, U.S.A. Eng. Pat. 6645, April 30, 1890. 1s. 3d.

THIS is essentially a direct reduction process in which the ore is reduced to a metallic sponge in a closed vessel by means of hydrocarbon gas, and subsequently smelted in the open-hearth furnace. The reduction vessel is a horizontal retort of suitable materials, supported within a furnace and communicating at the rear with an auxiliary chamber the bottom of which contains openings terminating in a passage-way leading to an open-hearth furnace.

The well-crushed and purified ore is charged from above into the retort previously heated to 1,500° F., treated with hydrocarbon gas and stirred at intervals (for about 3 or 4 hours) until the flame at the mouth of the gas outlet pipe subsides; the ore is then discharged through a door in the back of the retort into the auxiliary chamber where it is allowed to remain for a time with occasional stirring to facilitate its agglomeration into balls, and then either removed through the openings in the floor to trucks running in the passage below, or directly transferred to the open-hearth furnace by means of a grappling shovel.

A modification is described in which there is no auxiliary chamber, but the ore is treated in the retort with constant agitation rather longer (3 to 6 hours), and the sponge is withdrawn through a partially covered opening in the front of the retort into a closed vessel. Granulated charcoal or

coke may also be used as the reducing agent. Twenty-three claims are made for the mechanical details, which are illustrated in five sheets of drawings attached to the specification.—S. B. A. A.

Improvements in Converting Iron into Steel or the Steelifying of Wrought Iron Objects in a Manufactured or Partly Manufactured Slab. W. Hodge, Yutton. Eng. Pat. 7253, May 9, 1890. 6d.

THIS process is a modification of the ordinary method of cementation and differs from it in the substitution of carbonised or partially charred spent tan for the charcoal generally used. It is claimed that the resulting steel is not blistered and that the grain of the iron bars is not deleteriously affected so that the reheating or remelting is unnecessary. Articles of wrought iron may also be case-hardened by this process.—S. B. A. A.

Improvements in the Manufacture of Iron and Steel. J. von Langer, Leeds. Eng. Pat. 8459, June 6, 1890. 8d.

THE inventor proposes to reduce rich iron ores by injecting reducing gases bearing finely divided carbon into a bath of molten ore and flux in a basic lined open-hearth furnace.

A mixture of ore and charcoal finely crushed and mixed with a corresponding quantity of quicklime is introduced on one of the hearths of preferably a Pietzka's reversible duplex furnace (Eng. Pat. 6399 of 1890) heated to a high temperature, and a mixture of water, gas, and finely powdered charcoal or other form of carbon injected at a high pressure. The charcoal originally added to the ore reduces a portion of the iron which subsides in a highly carburised condition, and subsequently, when the temperature is raised, reduces a further proportion of the iron in the ore at the expense of its carbon; the gas and finely divided carbon reduces a further portion and recarburises the remainder of the iron, on again raising the temperature the carburised iron and ore again react. The slag must be kept basic if necessary by the addition of lime. Pig iron may also be added to the bath, but not more than 20 per cent. of the weight of the ore should be used. The waste gases are used for heating the furnace.—S. B. A. A.

A New Process for Recovering Tin from Tin-Plate in which Zinc-White is produced as a Product. A. McDougall, Southampton. Eng. Pat. 10,783, July 11, 1890. 6d.

ACCORDING to this specification tin plate is stripped by treating it with a saturated solution of litharge in caustic soda, metallic lead being precipitated and tin passing into solution. The treatment is continued until the solution is free from lead, and the tin is then precipitated in the pure state by means of scrap zinc or galvanised iron scrap. The zinc is recovered from the liquors by passing a stream of carbonic anhydride through them or by adding a soluble bicarbonate, zinc-white being formed.—S. B. A. A.

Improvements in Machinery or Apparatus for Coating Metal Plates or Sheets with Tin, Lead, or other Metals or Alloys. P. Rogers, Swansea, and J. Player, Clydach. Eng. Pat. 11,606, July 24, 1890. 8d.

THESE improvements are in the construction and arrangement of the apparatus described in Eng. Pat. 15,040 of 1886. A machine of this kind comprises a pot for the molten tin or alloy; a flux-box; a grease-box containing several pairs of finishing rolls; a cradle for directing the plates; a spring clip which receives the plates to be coated one at a time through the flux-box, carries them down into the molten metal and delivers them through a guide-box and a grease-box into the finishing rolls; a pick-up apparatus provided with mechanical fingers and adapted to automatically remove the finished plates one at a

time, and deposit them in a rack or other suitable receptacle; and mechanism for operating the several parts. The improvements described include a new form of guide, a modification of the cradle to adapt it for use in manufacturing the plates, an improved clip for working small plates, a modified form of pick-up apparatus, and lastly a new circular rack for receiving the finished plates. For the mechanical details of these variations the specification must be consulted.—S. B. A. A.

Improvement in Titanium Alloy and in the Manufacture thereof. J. Johnson, Liverpool. From J. W. Langley, Edgewoodville, U.S.A. Eng. Pat. 18,508, November 17, 1890. 4d.

Tin and iron tools that if pure aluminium be alloyed with between one half per cent. and 10 per cent. of titanium the product is harder than aluminium, nearly as incorrodible, and capable of acquiring by hammering or rolling a degree of elasticity and hardness much superior to pure aluminium. These alloys are fusible below the melting point of steel, the temperature required depending upon the percentage of titanium. When the proportion of titanium is less than 1 per cent. the alloy is nearly as malleable as pure aluminium. The presence of iron and silicon in this alloy are injurious, tending to render it brittle and non-malleable, but a small proportion of chromium is of substantial benefit in increasing the elasticity of the product. The alloy is prepared by the action of metallic aluminium on titanate oxide; the method used is also claimed for the preparation of alloys of aluminium with any more electro-negative metal and is as follows:—

A bath of preferably pure fluoride of aluminium and sodium is prepared in a carbon crucible, the oxide or other salt of titanium added, well mixed and allowed to dissolve; when the mass is thoroughly incorporated and quite fluid, metallic aluminium is charged in, the relative proportions of aluminium and oxide or salt being such that the percentage of oxide shall be about twice the percentage of metal required in the alloy. The temperature of the bath rapidly rises on the introduction of the aluminium, and as soon as this ceases, the reaction is completed and the mass is teemed into a suitable vessel, allowed to cool somewhat, and the fluid slag run off from the metal. The latter is remelted before use.

The proportion of fluoride used is from one to four times the weight of the aluminium; fluoride of sodium, fluoride of aluminium, sodium and calcium or generally a fluoride of any metal or metals more electro-positive than aluminium, may be used for the bath but cryolite is disadvantageous on account of the iron it contains.

The process must not be conducted in a siliceous crucible, a portion of the silicon being reduced and entering the alloy. Chromium may be introduced as oxide into the fluoride bath, or an alloy of chromium and aluminium may be mixed with the manufactured titanium alloy.—S. B. A. A.

Improvements in the Reduction of Iron Ores. J. Johnson, Pittsburg, U.S.A. Eng. Pat. 19,164, November 25, 1890. 4d.

This is a direct reduction process, and is alleged to be applicable to ores containing a high percentage of sulphur and phosphorus. The ore is crushed to the size of nuts, charged on to the hot hearth of a preferably end-radi-bottomed reverberatory furnace, and subjected to the action of a strong reducing flame for some time. From 20 to 40 per cent. of finely pulverised coke or charcoal is now shoveled on to the ore, the whole mass well riddled, covered with a light coating of pulverised carbon, and the heat raised until the iron becomes pasty. It is then bled and removed from the furnace. An addition of iron or steel scale may be made before introducing the carbon, and manganese, or the manganese slag from open hearth furnaces, may be added when highly carburised iron is required.—S. B. A. A.

A New Method of Utilising the Waste of Tin-Plates by Heating it with Fused Nitrate of Potash or Soda. H. C. W. Harmsen, Hamburg, Germany. Eng. Pat. 21,129, December 27, 1890. 4d.

According to this invention, scrap or waste tin-plate is stripped by heating it with molten saltpetre or sodium nitrate at a temperature not exceeding 400° C., the products of the reaction being insoluble oxide of tin and sodium nitrite. The operation is conducted in a large hemispherical vessel, in which about a ton of potassium or sodium nitrate is melted and kept as nearly as possible at a temperature of 400° C. An iron cage containing the waste tin is then lowered into the vessel, moved about in the molten mass for some time, then lifted out, and its contents discharged into a capacious drum or cylinder containing water and capable of revolving round an axis. When the whole of the saltpetre is converted into nitrite, the contents of the melting vessel are also thrown into the cylinder, the whole raised to the boiling temperature by injecting steam and slowly rotated. By this means the oxide of tin is completely detached from the iron, which is, however, again washed before being rejected. The nitrite of potassium or sodium is recovered from the liquors by crystallisation, &c.—S. B. A. A.

An Improved Amalgamator. H. Cook, Philadelphia, U.S.A. Eng. Pat. 2315, February 9, 1891. 8d.

This amalgamator consists of a rotating cylinder about 10 ft. long, in the interior of which an amalgamating surface is formed extending from the charging end for one-third of its length, and further fitted with a spiral retarding blade running from end to end. The discharge end of the cylinder is connected with the amalgamating tables by means of a chute, a trap for the amalgam fitted with an adjustable gate being interposed. The tables are provided with splash plates, accumulating wells for the amalgam, and a tailings indicator. The edges of the wells are lined with non-amalgamating plate, thereby breaking the continuity of the amalgamating surface and arresting the motion of the amalgam. For placer work the dirt is screened before charging by means of a suitably mounted transverse drum with concentric screens. The details of the above appliances, together with a modification available for use with coarse material, are described in the specification, 15 claims being made.—S. B. A. A.

Improvements in Apparatus for Treating Ore. J. R. Hallowell, Chicago, U.S.A. Eng. Pat. 3333, February 24, 1891. 8d.

This specification describes a combination of pulverising, concentrating, and dust-saving appliances, arranged so as to be capable of being worked continuously. The pulverising machine, which may be of any suitable construction, is supplied with hot air from a furnace chimney, and the ore, dried during crushing, is then drawn up through a screen into a chamber containing a number of partial vertical partitions, gradually increasing in height, by means of a suction fan situated at the top and back end of the chamber. The ore is thus graded by the successive partitions, the particles of ore being intercepted in the order of their specific gravity. Between each pair of partitions a hopper is disposed, communicating with a set of three or more automatically working screens, by which the ore is further concentrated. The fine powder and dust is drawn over by the fan into a dust chamber divided by sifting cloths into a series of concentric compartments. The dust which escapes from the chamber is further condensed in an adjoining tower provided with screens, movable shelves, &c.—S. B. A. A.

An Improved Alloy for Hermetically Closing Glass Tubes and other Purposes. F. Walter, Vienna, Austria. Eng. Pat. 7159, April 25, 1891. 4d.

It is claimed that an alloy consisting substantially of 95 per cent. of tin and 5 per cent. of copper may be used for connecting metals with glass, for electrical and other purposes, hermetically sealing glass tubes, &c.

The alloy is prepared by pouring the proper proportion of melted copper into the molten tin, stirring round with a wooden stirrer, casting or granulating and remelting. It adheres strongly to clean glass surfaces, and has nearly the same coefficient of expansion as glass; it melts at about 360° C. By alloying it with 0.5 to 1 per cent. of lead or zinc, it may be rendered softer or harder or more or less easily fusible as required. The alloy may also be used for coating metals or wires, as it imparts to them a silvery appearance.—S. B. A. A.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

PATENTS.

Improvements in Mandrils for Electrolytically Deposited Tubes. F. E. Elmore, Leeds. Eng. Pat. 7932, May 22, 1890. 6d.

THE mandrils are thin but stiff metallic tubes coated with a metal or other substance that is easily fusible by heat. This coating is preferably applied to the mandril by feeding the material between it and a second one also revolving close to and parallel with it, the first being kept cold and the second hot; the fusible material then adheres in a smooth polished coating to the cold mandril. If an insulating compound is used for the coating, the surface is covered with plumbago, and the whole is pricked through with numerous small holes reaching to the metal of the mandril, or the composition itself contains a salt which can be dissolved out, leaving the remainder porous. Gelatinous or gummy material mixed with plumbago may also be used. The deposited tube is easily removed by melting out the coating.—E. T.

A New or Improved Process for Obtaining, by Electrical Decomposition, Metallic Zinc from Solution of Sulphite of Zinc. E. Edwards, London. From T. Lange, Brieg, Germany. Eng. Pat. 8716, June 5, 1890. 4d.

Zinc sulphite is used instead of zinc sulphate as electrolyte, as the difficulty of keeping the bath neutral is thereby obviated, and the metal obtained of better quality. Less power is required for the decomposition of zinc sulphite than for that of zinc sulphate to the extent, it is stated, of 30 per cent.—E. T.

Improvements in Electric Reduction of Metals, and in Apparatus therefor. T. L. Willson, Brooklyn, U.S.A. Eng. Pat. 9361, June 17, 1890. 11d.

IN the ordinary processes of electrical reduction the electrodes and crucibles are attacked and rapidly wasted, and the oxygen liberated from the ore. To prevent this waste, the inventor forces in (preferably through the electrodes, which are made hollow for this purpose) some easily oxidisable material, such as illuminating gas, which combines with the oxygen as soon as the latter is liberated.—E. T.

Improvements in or connected with the Manufacture of Iron by Electrolysis. T. Parker, Wolverhampton. Eng. Pat. 9991, June 27, 1890. 4d.

THE inventor employs spongy iron as made in such processes as that described in Eng. Pat. 11,393 of 1889 (this Journal, 1890, 812). Such spongy iron is made by subjecting hematite or other good iron ore to the action of carbon or carbonaceous material at such a temperature as will effect reduction.—E. T.

Improvements in the Electrolytic Treatment of Metals. A. Watt, London. Eng. Pat. 10,038, June 28, 1890. 4d.

TO prevent the formation of irregular deposits of metal round the edges of the cathodes, resulting in "trees," which sometimes short-circuit the cell, the plates are enclosed in suitable frames of insulating material, which prevent any deposit from being thrown down at the edges.—E. T.

Improvements in Primary Batteries, and in Apparatus connected therewith. Sir C. S. Forbes, London. Eng. Pat. 18,180, November 11, 1890. 11d.

THE specification describes very elaborated arrangements for supplying liquor to the cells, regulating discharge, &c., involving the use of flexible tubes. It also refers to re-oxidation of spent liquors by blowing a suitable gas or gases through them.—E. T.

Improvements in Electric Batteries. H. H. Lake, London. From W. B. H. Dowse, Boston, U.S.A. Eng. Pat. 3589, February 27, 1891. 6d.

THE inventor prefers to use two or more porous pots containing zincs, the whole group being surrounded by a common electrode of copper. The solution used for the latter is copper sulphate; for the zincs, a solution containing sal-ammoniac and chromic acid, free or in combination, as essentials, and mercury bisulphate and hydrochloric acid if desired. With such solutions there is said to be no local action, even if the zincs are unamalgamated.—E. T.

Improvements in Electric Accumulators. H. H. Lake, London. From G. Gandini, Lodi, Italy. Eng. Pat. 5021, March 20, 1891. 4d.

THE electrodes are of lead oxide mixed with crushed carbon, the mixture being kept in place by suitable porous plates or pots, metallic conductors being interspersed. The carbon is used to increase the porosity of the plates.—E. T.

Improvements in Apparatus for Smelting or Casting. E. Taussig, Bahrenfeld, Germany. Eng. Pat. 6323, April 13, 1891. 6d.

THIS improved apparatus permits the smelting and casting to be conducted in a partial vacuum. It consists of an air-tight rectangular box with insulated electrodes fixed in the end walls, between which an electric current of sufficient intensity is passed through the charge of granulated metal. The moulds are similarly contained in an air-tight vessel moving on rails beside the furnace and having an adjustable air-tight connexion with the metal discharge pipe of the furnace. An air-pump connected with the discharge pipe exhausts both furnace and moulds.—S. B. A. A.

An Improved Alloy for Hermetically Closing Glass Tube and other Purposes. F. Walter, Vienna, Austria. Eng. Pat. 7159, April 25, 1891. 4d.

See under X., preceding page.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

On New Derivatives of Palmic Acid.—C. Hell and C. Jordani. *Ber.* **24**, 9, 6-903.

Bismuth bromide and monobromostearic acid obtained by heating stearic acid with bromine and water to 140° C. and Hell and Twerdom-dahl-bromo-hydroxy-amides and amide-myristic acids nothing is known of the derivatives of the higher members belonging to the fatty acid series. In order to fill up part of this gap, the authors have prepared and studied some derivatives of palmic acid. This latter was obtained by Kraft and Schmollin's method (*Ber.* **21**, 2265) from Japanese wax, repeated distillation gave a yield of 30 per cent. palmic acid, melting at 62° C.; palm oil by saponification, &c., only yielded 20 per cent. of an acid inferior in purity.

a Bromopalmitic Acid is obtained by the combined action of bromine and ammoniac phosphorus on palmic acid, then pouring the resulting fluid into water; the acid now forms an opaque yellow paste, having taken up over 16 times its own weight of water, which cannot be removed mechanically. The crystals deposited from the solution of the paste in ether or petroleum ether are pure bromopalmitic acid, and melt at 51.5-52° C.; they are insoluble in water and have now lost the property of absorbing water, and do not form an irritant to the skin. The *ethyl ether* of this acid boils at 121.5° C. (18 mm. pressure) is of a light red colour and fruity smell.

a Hydroopalmitic Acid is obtained by boiling bromopalmitic acid with excess of alcoholic potash and decomposing the potash salt with acid. If heated slightly with water the acid forms an emulsion, which, with increase of temperature, presently separates, swimming on the water as a yellow jelly, which solidifies on cooling. By dissolving in ether and recrystallisation from alcohol white crystals are obtained, melting at 82-83° C. The *copper, lead, and barium salts* are easily formed, also the *acetyl-derivative*, the crystals of which melt at 62.5° C., and form on solidification a yellowish porcelain-like mass.

a Amidopalmitic Acid is best obtained on heating a solution of bromopalmitic acid in alcoholic ammonia under pressure to 130-140° C., then distilling off the excess of both ammonia and alcohol, and separating the acid with water. The *acetyl-derivative* of this acid also is easily obtained, forming a dark red resin, soluble in ether and alcohol, while the amidopalmitic acid forms a crystalline powder, insoluble in ether and alcohol.

a Anilopalmitic Acid is obtained by heating to boiling bromopalmitic acid with excess of aniline for 3-4 hours. If boiling is continued till the whole mass is of uniform appearance the *palmitic anilide* is formed, which latter substance may be distilled without decomposition, at 282-284° C. (K. F. M.)

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

The India-rubber Tree.—Demetaria Argosy, May 9, 1891.

The india-rubber tree cannot stand shade, and unless the seedlings are fully exposed to light and well drained they cannot grow. Owing to this, it is found that in the depths of the forest, where light and air are shut out by the dense crowd of trees of many species, natural reproduction takes place by the germination of seeds carried by birds high up in the crowns of other trees, aerial roots descending in process of time to the ground, and developing into a huge hollow cylinder round the foster stem, which is soon killed. The descent of the roots may take years, but once they have taken hold of the ground the further growth is exceedingly rapid. In cultivating, the seeds are found to grow much better than cuttings, and these are tended in large nurseries until they are 10 ft. high, when they are transplanted into clearings made in the forest, in strips of 10 ft. wide, alternating with 60 ft. of natural forest, this being found necessary to furnish the necessary moisture, while narrower clearings do not give an air and light enough. Trees grown in grass land were found on tapping to yield scarcely any rubber, the difference being attributed to absence of the moisture afforded by the forest. Plants of 1874-5 were found, in April 1889, to have attained an average height of 64 ft. 11 in., and a girth of 11 ft. 5 in., thus having grown at the very rapid rate of 6 ft. 1 in. in height and 9 in. in girth per year.

PATENTS.

Process for Preparing an Elastic Caoutchouc-like Leather for Belts, Straps, and other Use.—C. Kuhue, Schönebeck, Germany. Eng. Pat. 8302, May 28, 1890. *Ad.*

The method of manufacturing the improved leather is as follows. The hide to be treated is first soaked in water, then carefully poked, unhaired and rinsed, after which it is immersed in a weak lime and subsequently washed in clean water. The hide is next immersed in a bath of "light argilnauk" (a weak mixture of alumina and water), then smoothed, scraped and trimmed. In this cleaned condition the hide is brought into "a good sour-water" and again worked on the beam. When the hide is air-dry it is lightly brushed on both sides with a mixture of glycerol and linseed oil, which must be so applied as to properly soak into the hide. The drying and oiling are repeated and the hide is finally dried. The whole process is so conducted as to last for about 10 days. (R. H.)

Improvements in Machinery for Working Leather, Hides, and Skins.—E. Wilson, Exeter. Eng. Pat. 2609, June 20, 1890. *sd.*

This invention relates principally to improvements on the machines described in the specifications of Eng. Pats. 5228 of 1880, and 3444 of 1887, and its main object is to simplify the construction, reduce the cost and diminish the wear and tear of such machines. The specification is unsuited for abstraction, and would be unintelligible without the accompanying drawings. (R. H.)

Improvements in Machines for Colouring Leather. S. Skueck and F. Jelen, Prague, Austro-Hungary. Eng. Pat. 5786, April 3, 1891. 8d.

This invention is for a leather-colouring machine the characteristics of which are a rotatory roller upon which the leather to be coloured is stretched and covered with a cloth suitably clamped, the colouring being effected by special brushes charged with colour, which force the ink or colour through the meshes of the cloth on to the leather. Drawings are given and the specification must be consulted for a description of the mechanism. —B. H.

An Improved Substitute for Leather. E. Drew, London. Eng. Pat. 6852, April 24, 1891. 4d.

THE basis of the leather substitute consists of specially prepared boards of wood. The board, preferably selected American ash, is reduced by sawing to an equal thickness throughout of about an eighth of an inch, and the surfaces are left quite rough so that the covering material will adhere firmly. The wood is then dried to prevent its splitting and is subsequently coated on each surface with a special adhesive preparation, which being waterproof prevents the wood from being affected by moisture. The surfaces of each side of the wood are then covered with waterproof canvas or other suitable material, which adheres by means of the glue. The whole is then pressed and dried at a temperature of 60°. The adhesive preparation referred to above is composed of the following ingredients:—10 lb. of best Scotch glue, 3 lb. of marine glue, and 1 lb. of plaster of Paris, and is made by melting and well mixing them.

—B. H.

XV.—MANURES, Etc.

Culture of the Colza-Oil Plant. E. Louise and E. Picard. Compt. Rend. 112, 903—906.

THE authors have made experimental cultivations of the colza-oil plant, with the object of determining the exigencies of its growth in ordinary ground; and the nature of the manure best suited for its development. A variety of colza seed was chosen which is most commonly employed in Calvados. The seed was sown in ground of known composition. Towards February the plants began to vegetate, and samples were taken monthly for analysis, the roots, stems, and leaves being examined separately. The analytical results showed that during the period of growth from February to June 28th, when the plants reached maturity:—

1. The percentage of *nitrogen* decreased continuously in the roots and stems, but increased in the leaves.
2. The *phosphoric acid* decreased in a similar manner in the roots and stems, whilst in the leaves it attained a maximum on June 8th.
3. The *potash* diminished continuously in the roots and leaves, but remained constant in the stems.
4. The *lime* increased continuously in all parts of the plant, and reached its maximum on June 8th.
5. The *magnesia* also increased in all parts of the plant.

The total weight of the dry plants was also determined, so that the total amount of mineral matter removed from the soil could be calculated. The results also show that although the percentage of ash in the plants decreased during their period of growth, yet the total amount of mineral matter absorbed from the soil increased continuously. Of the various mineral substances pre-existing in the soil the following amounts were removed by colza crop:—

Phosphoric acid	$\frac{1}{3}$
Nitrogen	$\frac{1}{10}$
Potash	$\frac{1}{4}$
Magnesia	$\frac{1}{10}$
Lime	$\frac{1}{2}$

It appears, therefore, that the colza plant impoverishes the soil chiefly of phosphoric acid, nitrogen, and potash, and that phosphatic manures will be of considerable importance in the cultivation of the colza plant. —H. T. P.

PATENTS.

Improvements in Apparatus for Desiccating and Sterilising Waste Animal Substances to obtain Manure, and for Extracting Fat therefrom. H. H. Lake, London. From F. de la Croix, Antwerp, Belgium. Eng. Pat. 9476, June 13, 1890. 8d.

THE object of this invention is to extract the fat from meat unfit for consumption, bad fish, and all kinds of refuse from slaughter-houses. The apparatus employed consists of a closed cylinder in which the meat, bones, &c. rest on a perforated false bottom covered with cloth or fine wire gauze. The cylinder is provided with a steam jacket and also with a number of steam inlets to the body of the apparatus, chief of which is a pipe perforated in numerous places placed in the centre of the cylinder. The apparatus being charged and the cover fastened down, steam is at first only admitted to the jacket in order to heat the charge and prevent, as much as possible, the extraction of the water soluble constituents of the meat, &c. by condensed steam. When sufficiently heated, superheated steam is admitted to the cylinder through the central tube and other inlets. After some time, the fat which filters through the false bottom is drawn off into a reservoir partially filled with cold water. Steam is then shut off from the interior of the cylinder and the charge is dried by the heat from the steam-jacket. The residue is finally withdrawn through a man-hole near the bottom of the cylinder, and completely dried, if necessary, in the ordinary way. The dried mass after grinding forms manure. The vapours arising from the charge during steaming are passed into the boiler flue, by which means all bad smells are obviated. For detail and drawing of the apparatus the original specification must be consulted. —H. T. P.

Improved Apparatus for Drying and Mixing Bones and other Substances. A. H. Hobson, London. Eng. Pat. 10,562, July 8, 1890. 6d.

See under 1, page 625.

Improvements in Process for Making Superphosphatic Manure. O. Jaehne, Vienenburg, Germany. Eng. Pat. 5111, March 21, 1891. 4d.

Raw ferruginous phosphates are ground up with a weak solution of sodium bisulphate and the solution of mono-calcium phosphate thus produced is evaporated to dryness. Or the same materials may be ground up with less water to form a pulp, ready when solidified for use as manure. The application of bisulphate instead of sulphuric acid has the advantage that an excess may be used without risk of the pulp not becoming solid. —G. H. B.

The Role of "Mechanical" Filtration in the Manufacture of Raw Sugar. E. Donath. *Zeits. f. angew. Chem.* 1891, 23, 1-238.

The quantity of raw sugar manufactured without animal charcoal has increased year by year since the introduction of improved methods of treating the juice, and in the place of the battery of charcoal stoves, mechanical filters of various construction are used. The author has made the experiments described below to ascertain the precise part played by the latter; he has examined certain muddy deposits from the filter-bags, as well as portions of the stained cloths. The deposits were carefully scraped off and dried.

A. Muddy coating, consisting essentially of defecation-mud, from the outside of filter-bags used for thin juices. In the moist condition it fermented after some days. Analysis:

	Per Cent.
Wet extract (including sugar) (1 per cent.)	7.12
Extract of fatty acids	2.45
Oil and fatty acids	0.90
CO ₂	36.41
Ash (after deducting CO ₂)	52.34
	<hr/> 99.22

The ash consisted chiefly of calcium oxide and carbonate.

B. Very dark greasy deposit from the outside of filter-bags used for concentrated juices; on drying a fatty odour was recognised. Analysis:—

	Per Cent.	Per Cent.
Oil and fatty acids	8.68	71.70
Wet extract (including sugar) (1 per cent.)	9.46	
CO ₂	1.97	
Ash (after deducting CO ₂)	8.58	
	<hr/> 99.68	

The ash contained:

	Per Cent.
SiO ₂	37.12
CaO	2.10
CO ₂	2.73
CaO	1.50
FeO	1.12
Al ₂ O ₃	18.52
P ₂ O ₅	0.39
SO ₃	1.64
K ₂ O	18.74
Na ₂ O	3.21
Chlorine, sulphur, and iron in solution	Traces

C. A strip 32 × 48 cms. of the filter-fabric from which B. was obtained; it was a deep chestnut brown colour, weighed 17.9 grms. and yielded 3.079 grms. of ash; when treated with hydrochloric acid chlorine was evolved; whilst a similar strip of the unused material weighed 14.38 grms. and gave 0.126 gram. of ash. The ash of the stained material had the composition:—

	Per Cent.
SiO ₂	6.14
CaO	0.17
Fe ₂ O ₃	32.84
Al ₂ O ₃	3.75
Mn ₂ O ₃	0.20
MgO	0.94
CaO	1.49
CO ₂ &c.	Not determined.

D. Very greasy grey deposit, evolving on drying the odour of rancid fat, from the outside of a filter used for concentrated juices. Its volatile constituents amounted to 58.07 per cent., including sugar, 5.45 per cent.; fat, 7.14 per cent.; fatty acids, 8.67 per cent.; and CO₂, the amount

of which was not determined. The ash had the following composition:—

	Per Cent.
SiO ₂	36.30
CaO	2.22
Al ₂ O ₃	11.82
Fe ₂ O ₃	1.70
CaO	26.13
MgO	0.70
K ₂ O	1.95
Na ₂ O	7.60
P ₂ O ₅	7.61
CO ₂	4.55

E. Ash of the filter-fabric from which D. was separated; 10.8 per cent. was obtained and it was of a light brown colour. It gave the following results on analysis:—

	Per Cent.
SiO ₂	87.64
CO ₂	0.27
CaO	0.2
Al ₂ O ₃ and Fe ₂ O ₃	1.98
CaO	0.50
MgO	5.60
Mn ₂ O ₃	0.48
SO ₃ and P ₂ O ₅	Not determined.

The alkalis set free by the lime used in defecating, probably react with the silicates which the latter contains, and this accounts for the high percentage of SiO₂, as also for the Al₂O₃ found in the ash of the muds and of the fabric E., whilst the solubility of calcium phosphate in sugar solutions probably accounts for the P₂O₅ found. The aqueous extract from A. gave on addition of an equal volume of 85 per cent. alcohol, a small quantity of a curdy precipitate, which after purification by repeated redissolving in water and reprecipitating with alcohol appeared to contain dextran.

From his results the author is inclined to think that this process of filtration with thin juices is purely a mechanical one; with concentrated juices, however, which during concentration have dissolved out certain oxides by contact with corroded metallic surfaces, it appears different, as these oxides are afterwards taken up by the filter-fabric and act as mordants (see below). The manganese which precipitates on the fibres from the hot concentrated juices seems to undergo oxidation, so that a manganic compound resembling the Weldon mud results; hence the fact that chlorine was evolved on treating the coloured fabric with hydrochloric acid. Since, however, the coloured fabrics contain more organic substances than the unused material, it would appear that the colouring matters of the concentrated juices are taken up by the former through the agency of the above-mentioned metallic oxides, the process being similar to that of dyeing, and in this respect the part played by the mechanical filter may be regarded as a chemical one. By the protracted boiling which the concentrated juice has undergone, the fat is saponified and to some extent decomposed by the lime, and is retained by the filter-fabric together with the precipitated silicates.—A. R. L.

On the Dissociation Hypothesis; on Cryoscopic Method; and on the Freezing Points of Aqueous Solutions of Cane Sugar. J. Traube. *Ber.* 24, 1321-1327.

PATENTS.

Method of and Appliances for the Collection and Utilisation of the Carbonic Acid Gas and other Products given off during the Process of Fermentation. C. R. C. Tichborne, A. E. Darley, M. F. Purcell, and S. Geoghegan, Dublin. Eng. Pat. 9183, June 13, 1890. 8d.

THE inventors have previously taken out a patent (Eng. Pat. 3707, of 1889; this Journal, 1890, 537) for the general process, and this patent relates to improvements of it.

The gas is collected from an open fermenting vessel by a funnel or bell so arranged that its lower edge may be just above the fermenting head or just dipping into it, as most convenient. A diaphragm is suspended over the funnel to prevent a vortex being formed in the upper atmosphere of the vessel during the withdrawal of the carbonic acid, which would cause air to follow and become mixed with the carbonic acid.

The carbonic acid may also be extracted by a funnel placed in the fermenting liquid so that its upper edge is just above the level of the liquid, or by pipes placed at different heights in the side of the fermenting vessel.

The gas thus collected is passed through a cotton-wool filter or a heated tube to remove or destroy all ferment germs; then through a washing tower containing water free from oxygen to absorb the small quantity of oxygen which is invariably present; then through another tower containing sulphuric acid to remove all alcoholic and ethereal vapours; and the purified gas is then condensed by a series of stage condensing pumps.—A. L. S.

Improvements in Apparatus to facilitate the Fining of Beer. L. C. Best, London. Eng. Pat. 9442, June 18, 1890. 6d.

THE apparatus consists of a small bowl-shaped funnel, the narrow end of which fits the bung-hole of the cask.

A small quantity of beer is drawn from the cask in the usual manner, and the finings are added. The bowl is then fitted to the bung-hole, when the beer withdrawn from the cask or other beer is run into the bowl till it is about half full; as the fining action proceeds, the finings rise and displace the beer in the funnel. At the completion of the action, a small plug is inserted into the neck of the funnel, and the spent finings removed.—A. L. S.

Improvements in or connected with Apparatus for Drying Granular Substances. J. H. R. Dinsmore, Liverpool. Eng. Pat. 10,888, July 12, 1890. 8d.

See under L., page 625.

A Novel Preparation for Fining and Frothing or imparting a Foam to Beer and other Fermented Beverages. T. Reade, Wolverhampton. Eng. Pat. 11,613, July 24, 1890. 6d.

A SOLUTION which is both a frothing and fining agent is prepared by extracting one hundredweight of quillaia bark by three successive quantities of 40 gallons of water, each for 24 hours. The whole extract is used to dilute a strong solution of isinglass to 300 gallons; the strength of the isinglass solution being such that when diluted to this bulk it is of the ordinary strength used for finings.—A. L. S.

Improvements in Malt Liquors, Wines, and Spirits. F. T. Simpson and J. Cox, London. Eng. Pat. 16,942, October 23, 1890. 4d.

KOLA, or the active principle thereof (caffeine) is added to malt liquors, wines, or spirits with the object of imparting to them or strengthening the property of retarding the wear of the tissue of the human body.

The proportions recommended are: To a gallon of malt liquor 16—32 grains of caffeine; to a gallon of wine or spirit, 72—144 grains.—A. L. S.

Improvements in the Method of and Apparatus for Purifying and Refining Alcoholic Liquors and other Fluids. S. Mason, jun., Manchester. Eng. Pat. 7140, April 25, 1891. 6d.

IN order to oxidise the fusel oil in spirits and other impurities of various liquors, the liquid is exposed in the form of a spray to a current of air, and the air passing through the spray allowed to escape. This is repeated until the desired result is produced. The description of an apparatus for this purpose is included in the specification.

—A. L. S.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

(A.)—CHEMISTRY OF FOOD.

PATENTS.

Improvements in the Manufacture of Aerated or Mineral Waters and Beverages. H. C. Saunders, Penge. Eng. Pat. 9100, June 12, 1890. 4d.

TUBES containing soda and tartaric acid in a compressed state, along with flavouring materials, are introduced into bottles or other closed vessels containing water, for the production of aerated drinks.—G. H. B.

Improved Process for Sterilising Milk. F. A. Raedler, Westerrade, Germany. Eng. Pat. 10,563, July 8, 1890. 4d.

FRESH cows' milk is placed in a digester and cooled to 10—15° C. The vessel is then closed and the milk is rapidly heated to 115°—150° C., and maintained at this temperature for 15—60 minutes. If only required to keep sound for a few days the milk is heated to 115° C., but when intended for transport or long storage it should be heated to 150° C. for one hour. A small quantity of sugar is added to the milk to prevent the separation of butter during transport.—H. T. P.

Improvements in Sterilising Apparatus. J. F. H. Gronwald and E. H. C. Oehlmann, Berlin, Germany. Eng. Pat. 3902, March 4, 1891. 6d.

THE improvements relate to that kind of apparatus in which bottles contained in a closed vessel are closed by means of a presser operated on from the outside. This may be effected in two ways, either the tray carrying the bottles may be forced upward against the presser, or the presser may be drawn or forced down upon the bottles. The power employed may be liquid, steam, air, or other fluid pressure controlled by suitable external appliances. The two methods are shown on the drawing attached to the specification.—E. S.

Improvements in Food Preservation.—H. Watty, Weston-super-Mare. Eng. Pat. 7485, April 30, 1891. *Ad.*

Meat, fish, game, &c. are preserved by wrapping them in muslin, calico, paper, or any other suitable fabric impregnated with boracic or salicylic acid, or with a mixture of the two. The fabric to be employed is soaked in or sprinkled with a solution prepared in either of the three following ways:—

1. Commercial boracic acid, 1 lb.; water, 5 galls.
2. Commercial salicylic acid, 1 lb.; water, 5 galls.
3. Salicylic and boracic acids, of each 1 lb.; water, 10 galls.

The fabric, being charged with one of these solutions, is dried by exposure to air, or by heat, and is then ready for use. H. T. P.

(B).—SANITARY CHEMISTRY.

PATENT.

Improved Means for Deodorising, Disinfecting, Oxidising, and for Absorbing Secretions of the Human Body.—J. W. Dougal, Lanlithgow. Eng. Pat. 8861, June 7, 1890. *Ad.*

CARBON in the form of charcoal, bone black, or prussiate charcoal is incorporated with the various materials of which articles of clothing are made. The carbon may be introduced more particularly into the in-soles, &c. of boots and shoes, into arm put and other pads, and into chest protectors, &c. In manufacturing the material for in-soles, &c., zinc and copper wires, and some suitable salt may be introduced along with the carbon in order to produce electrical effects.

The inventor also employs carbon in combination with other substances, such as magnetic oxide of iron, fuller's earth, magnesium silicate, kieselsäure, tale, starch, salicylic acid, phenol, cresol, salt, alum, boracic acid and its salts, metallic nitrates, chlorides, and sulphates, and other bodies. —H. T. P.

XIX.—PAPER, PASTEBOARD, Etc.

Estimation of Mechanical Wood Pulp in Paper.—W. Herzburg. Mitt. Königl. Versuchs. 1891, 44–59.
See under XXIII., page 661.

PATENT.

Improvement in and Relating to Processes and Apparatus for Disintegrating Vegetable Substances for the Production of Fibres therefrom.—A. Solkirk, Albany, U.S.A. Eng. Pat. 5597, March 31, 1891. *Sd.*

FIBRES suitable for the manufacture of paper and similar articles are obtained from wood, straw, grasses, and other vegetable substances by introducing the materials to be treated into a strong iron or steel digesting vessel in the form of a cylinder with semi-spherical ends, and provided with a perforated chamber in the centre, and with perforated plates at the top and bottom for regulating the supply of the digesting liquor. This vessel, when filled with the raw material, is tightly closed, and the liquor introduced into it from the top and bottom simultaneously. After thoroughly impregnating the whole mass of the material, the liquor passes out through the central chamber. While in the digester it is kept in circulation by a pump and a series of pipes connected with an apparatus for heating it, when required. The degree of heat and pressure within the digester, and the rapidity of the circulation of the liquor vary considerably according to the nature of the material to be treated. When the latter is properly disintegrated, the operation is finished by drawing off the liquor and removing the substance from the digesting vessel. —H. S.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

The Physiological Action of the Parafrinic Nitrites considered in Connection with their Chemical Constitution. Part I. The Action of the Parafrinic Nitrites on Blood Pressure.—J. T. Cash and W. R. Dunstan. Proc. Royal Soc. 1891, 49, 314–319.

PREVIOUS investigators on the physiological action of the organic nitrites have dealt almost exclusively with amyl nitrite, and the results obtained therewith are, in the opinion of the authors, vitiated by the facts that insufficient pains have been taken to procure the nitrite in a chemically pure state, and also that the mode of administration has been such that it is impossible to determine exactly how much of the compound has actually been inhaled.

Both these sources of error have been obviated, the nitrites employed having been analysed in all cases, and specially devised forms of apparatus having been employed for ensuring, without loss, the inhalation of a definite amount of nitrite, through the trachea in animals and through the nostrils in the human subject. The nitrites were prepared by the action of sodium nitrite, in presence of dilute acid, on the corresponding alcohol. The product of the reaction after washing and drying was purified by fractional distillation, in some cases under reduced pressure.

Details of the method of administration and of the apparatus employed are given. The experiments were conducted on cats, rabbits, and on the human subject. All the nitrites examined produce, in whatever way administered, a reduction of blood pressure, the extent of the reduction, when equal volumes are administered to animals by inhalation, being in the following order:—(1) Secondary propyl, (2) tertiary butyl, (3) secondary butyl, (4) isobutyl, nearly equal to 3, (5) tertiary amyl, (6) α -amyl, (7) β -amyl nearly equal to 6, (8) methyl, (9) butyl, (10) ethyl, (11) propyl. This order is somewhat modified when the nitrites are given by intra-vascular injection. When the duration of the sub-normal pressure is considered, the order is nearly the reverse of that given above, the effect of methyl nitrite being the last, and that of the secondary propyl nitrite one of the first to appear. The pulse acceleration produced by these nitrites does not follow in the above order, the amyl nitrites, in particular, being more active. The experiments on the human subject go to show that there is a considerable variation on the part of individuals to nitrite effect, the acceleration of the pulse in the case of those of neurotic tendency being much greater, and the time of its continuance much less than in that of a lymphatic subject. The order of activity (extent of acceleration) of the various nitrites was found to be as follows: (1) α -amyl, (2) β -amyl, (3) isobutyl, (4) secondary butyl, (5) primary butyl, (6) secondary propyl, (7) primary propyl, (8) ethyl, (9) methyl. The extent of the acceleration appears to be less in the case of cats than in the human subject.

In subsequent communications the authors intend to discuss the action of these nitrites on striated muscle and the relationship of all these physiological effects to the chemical constitution of the nitrites employed.—C. A. K.

Derivatives of Salol.—W. Knebel. J. Prakt. Chem. 1891, 43, 378–389.

Acetyl Salol, $C_6H_5(CO.CO.CH_3)CO.OC_6H_5$, is prepared by the action of acetyl chloride or of acetic anhydride on salol. It forms star-like crystals melting at 97° C.

Nitro-derivatives of salol.— α -mono-nitrosalol—

results when salol in glacial acetic acid solution is treated with nitric acid of sp. gr. 1.525, and the mixture allowed to stand. Crystals of the nitro-compound separate, which, when recrystallised from glacial acetic acid, form

colourless needles, which melt at $150-151^{\circ}\text{C}$. On saponification with alkali, phenol, and nitro-salicylic acid ($\text{CO.OH}:\text{OH}:\text{NO}_2 = 1:2:5$) result. The same nitro-compound is formed by nitrating salicylic acid and treating the nitro-acid formed with phenol and phosphorus oxychloride as in the preparation of salol. β -nitro-salicylic acid ($\text{CO.OH}:\text{OH}:\text{NO}_2 = 1:2:3$) similarly treated forms β -nitro-salol which crystallises from alcohol in prisms melting at 101°C . It is not obtained by the direct action of nitric acid on salol. Both α - and β -nitro-salol yield acetyl compounds, the former melting at 118° , the latter at 95° . When acetyl-salol is nitrated the acetyl group is removed and α -nitro-salol results.

By the further action of nitric acid either upon salol or upon acetyl-salol *di-nitro-salol*, $\text{C}_6\text{H}_2(\text{NO}_2)_2(\text{OH})\text{CO.OC}_2\text{H}_5$, is formed, which, recrystallised from glacial acetic acid, forms fine needles, melting at 183° . When saponified dinitro-salicylic acid and phenol result. It yields an acetyl compound, melting at 118° . Together with the dinitro acid, some picric acid is formed in the reaction.

When further nitrated two trinitro-salols are formed, in which the nitro groups enter the phenyl group of the carboxyl phenyl. Some picric acid also results.

(1.) 1:2 nitrophenyl dinitrosalicylic acid—

Salol is added to nitric acid of sp. gr. 1.525 mixed with concentrated sulphuric acid. The reaction is violent. The nitro compound is separated by pouring the product of the reaction into water and recrystallising the separated trinitro-salol from alcohol after repeated boilings with water. It forms glittering plates which melt at 100° . When saponified 1:2 nitrophenol and dinitrosalicylic acid result.

(2.) 1:4 nitro-phenyldinitrosalicylic acid—

This is formed together with the 1:2 compound in the above reaction, and is separated from it by extracting the mixed nitro-compounds after precipitation with water, with glacial acetic acid, the 1:2 compound being left behind. It crystallises in pale yellow needles, melting at 176° , and on saponification forms 1:4 nitrophenol and dinitro-salicylic acid. It yields an acetyl compound which melts at 156° .

The author was unable to prepare these trinitro-salols either from salicylic acid or from salol by direct nitration.

—C. A. K.

On some Derivatives of Benzoic Sulphinide (Saccharine or Benzoyl Sulphonic Imide), and the Changes caused in their Taste by Changes in Composition. R. de Roode. Amer. Chem. J. **13**, 217—232.

THE most characteristic property of parabromosulphinide is that it possesses two distinct tastes, a bitter and a sweet, and the corresponding chlorine compound has the same peculiarity in even a more marked degree. The author has therefore investigated the other para-halogen-sulphinides, and the substances from which they are made, and observed their effect upon the nerves of taste.

The starting point for their preparation was paradiazotoluene-orthosulphonic acid, which was converted into para-fluorotoluene-orthosulphonic acid by heating with concentrated hydrofluoric acid in a platinum dish until the decomposition was complete, evaporating to a syrupy consistence, diluting with a large quantity of water, and neutralising with barium carbonate (the calcium salt not being easily crystallisable). From the barium salt the potassium compound was obtained by treatment with potassium carbonate. This latter salt crystallises from water in large glistening scales, containing two molecules of water of crystallisation. The corresponding chlorine and bromine salts were prepared in a similar manner, potassium chlorotoluenesulphonate crystallising in light yellow needles containing no water, and the bromotoluenesulphonate in thin lustrous scales containing 1 mol. of water of crystallisation. For the preparation of the iodo-salts the diazo compound was decomposed by hydriodic acid in presence of alcohol, the flask being

kept cool: after the evolution of nitrogen had ceased the contents were warmed and the alcohol distilled off. The residue was diluted with a large quantity of water, neutralised with lead oxide and filtered hot. The lead salt being insoluble could not be easily freed from the excess of oxide, and was converted into the potassium salt, which crystallised from aqueous solution in transparent "whetstone-shaped" crystals containing 1 mol. of water and corresponding to the potassium salt of the β -iodotoluenesulphonic acid described by Glassner (Ber. **8**, 561). Accompanying the insoluble lead salt was another which was very soluble: it was not examined as such, but was converted into the potassium salt, and on analysis gave figures corresponding to potassium toluenesulphonate.

From these four potassium salts, the corresponding amides were prepared by the action of phosphorus pentachloride, followed by aqueous ammonia. The solutions were evaporated to dryness on the water-bath, alcohol added, and after treatment with animal charcoal crystallised out. With the exception of the iodo salt, all are easily soluble in hot water and alcohol, sparingly soluble in cold water. The melting point of the fluorine salt is 155° , of the chlorine salt, 145° ; and of the iodine salt, $185-187^{\circ}$ (uncorrected). From these amides, the sulphinides (sulphonic imides) were prepared by oxidation with alkaline permanganate, the most successful method of working being found to be as follows:—20 grms. of the amide and 8 grms. of caustic potash were dissolved in two litres of water in a large flask, and placed on the water-bath. A concentrated solution of 35 grms. of potassium permanganate was then added by degrees, the flask being kept hot until only a slight pink colour remained, an operation lasting about six or eight hours. A little alcohol was then added and the liquid filtered and evaporated to about 75 cc. While still hot, the sulphinide, together with some unaltered amide was precipitated with strong hydrochloric acid; to separate them the mixed precipitate was boiled with water, neutralised with chalk, filtered and allowed to cool, the amide crystallising out in long white needles. On further evaporation the calcium salt of the sulphinide was obtained. These all crystallise in radial groups of white needles, having the same tastes as the sulphinides themselves, and containing $7\frac{1}{2}$ molecules of water of crystallisation. From these calcium salts the pure sulphinides were obtained by precipitation with strong hydrochloric acid.

Parafluorosulphinide, thus prepared, crystallises from hot water in long white needles, which break up on drying into granules; from a dilute solution it may be obtained in small transparent rhombs. Its melting point is $200-202^{\circ}$ (uncorrected). Its taste is almost purely sweet, a slight bitter after-taste being perceptible. It is probably as sweet as benzoic sulphinide.

Parachlorosulphinide crystallises in thin pearly scales, melting at 218° . It is slightly less soluble than the fluorine compound. It has both a sweet and a bitter taste, the latter being the more intense.

Parabromosulphinide also possesses both tastes, but in a less marked degree, and *para-iodosulphinide* has only a slight bitter taste. The latter crystallises in fine white needles and melts at $230-232^{\circ}$. On boiling with dilute hydrochloric acid, *p*-chlorosulphinide is converted into the acid ammonium salt of *p*-chlorotoluenesulphobenzoic acid, just as benzoic sulphinide is, into that of orthosulphobenzoic acid.

With regard to the tastes of these halogen derivatives it is found difficult to describe the differences accurately; they have been tasted by several, the majority of whom agree with the author in his description. "It is, however, impossible to make accurate comparison between a sweet and a bitter taste as regards the relative intensity of the two."—F. H. L.

Studies of the Terpenes and Allied Compounds. The Nature of Turpentine Oils, including that obtained from Pinus Khasyana. H. E. Armstrong and W. J. Pope. Journ. Chem. Soc. **343**, 1891, 311—320.

THE crystalline substance of the formula $\text{C}_{10}\text{H}_{16}\text{O}_2$, briefly described by Sobrero in 1851 (Compt. Rend. **33**, 66; Annalen, **80**, 106), was obtained by exposing oil of turpen-

the together with moist oxygen to sunlight. Sobrero stated that, when boiled with dilute sulphuric acid, it was converted into a volatile product having a strong odour resembling that of camphor as well as that of turpentine.

Probably Sobrero had worked with French oil of turpentine, and therefore this was first submitted to air-oxidation in sunlight, the results obtained were in complete accordance with the account given by Sobrero. On substituting American for French turpentine a substance was obtained identical with that resulting from the oxidation of the French hydrocarbon, except in its optical characters.

These results led the author to study the behaviour of oils from various sources containing $C_{10}H_{16}$ hydrocarbons, in the hope that information might be gained which would serve to elucidate the complex problem presented by the existence of an apparently infinite variety of essential oils.

It was soon ascertained that a clear atmosphere and a bright, high sun were requisite for the formation of the crystals. It has rarely happened that crystals began to form until late in May, and each exposure has usually lasted from two to three months. Necessarily, therefore, the information has been acquired at a slow rate.

The hydrocarbons of the formula $C_{10}H_{16}$, derived from plants, may be divided into two classes, viz., (1) those boiling at about 156° , which are conveniently termed *terpenes*, as they are the chief constituents of ordinary turpentine oils; and (2) those boiling at about 176° — 178° , which may be termed *citrenes*, as they are the chief constituents of the oils derived from the various species of *Citrus*. The terpenes and citrenes are all capable of rotating the plane of polarisation of light, but no two plants furnish terpenes or citrenes of identical rotatory power, and often different parts of the same plant yield different products. The different terpenes appear, however, to agree in all other physical properties, and also in their chemical properties, and the same is true of the different citrenes. It is probable that the number of isomerides of the formula $C_{10}H_{16}$ is very much smaller than has been supposed, and that the differences observed in the rotatory powers of the hydrocarbons from various sources are due to their being mixtures in varying proportions of two or more isomerides.

In a paper read before the Society of Chemical Industry in 1882 (this Journal, 1882, 478), detailing the results of the examination of a very large number of samples representing many thousand barrels of different kinds of commercial turpentine, after calling attention to the almost absolute uniformity of the French oil and the wide variation which was noticeable on comparing the rotatory powers of different samples of the American oil, the author stated that he had been led to think it not unlikely that the low dextro-rotatory power of American turpentine is due "to the presence of a levo-rotatory terpene; this would serve to explain the difference in optical character of products from different localities." That this is actually the case, he has no longer any doubt. The crystalline product from French turpentine is all but inactive, that from American turpentine is, but rarely so. The earlier crystallisations usually consist of a substance which may be said to be the image of that from the French oil but although the crystals in later fractions may exhibit the same melting point as those separated at an early stage, the rotatory power of the fraction as a whole is lower. The explanation of the difference was discovered in the course of the examination of a very beautiful turpentine oil from British Borneo, the product of *Pinus Khasiana*. This oil appears to be in every respect the counterpart of French turpentine but its optical image, and if it could be obtained in quantity would form a most valuable article of commerce. The air oxidation product of the Khasiana terpene is the image of that from French turpentine, and identical with that obtained from American oil, the difference in the Borneo and American oils being that the former, like the French oil, affords a more or less uniform product.

When the two varieties of equal opposite rotatory power of the oxidation product are mixed, an inactive substance is obtained of much lower melting point, and it is this substance which is present in considerable quantity in the product from American oil along with the dextro-rotatory active form. The melting point observed in the case of the later fractions of the product from American turpentine is

a matter of accident, for if the crystal used in the determination be not specially selected from the mass, it may be either the active or the inactive substance.

As the relation of the crystalline oxidation product to the parent hydrocarbon cannot yet be determined, and as it is not improbable that, as in other cases, a molecular change has attended its formation, and that it is not a simple derivative of the hydrocarbon, the author suggests that in giving it a name (as one or both of its oxygen atoms possess alcoholic functions), to recognise its discovery by Sobrero, it be termed *sobrero*.

The author thinks that *sobrero* is only obtainable from the terpenes proper, and that, according as an oil yields either dextro- or levo-*sobrero*, or a mixture of either modification, with the inactive form, it is to be regarded as containing one or other of the corresponding terpenes, or, as in the case of American turpentine, a mixture of the two. In other words, that there are but two terpenes, viz., those represented by the essential components of the French and Borneo oils.

Bearing in mind that we are indebted to Berthelot for the first systematic study of the varieties of turpentine oil, and that he proposed the name *terebenthene* for the characteristic hydrocarbon of such oils, it is proposed to term the two optically different varieties *dextro-terebenthene* and *levo-terebenthene*.

The oil which Sobrero obtained by distilling the crystalline oxidation product with acid has proved to be identical with the isomeride of camphor which Wallach and Otto obtained by the interaction of turpentine and nitrous acid (Annalen, 153, 219), which they have named *pinol*. Being a strict adherent to the view that the *ol* termination should be reserved for hydroxy-derivatives exhibiting alcoholic functions, as the compound does not appear to be of this class, the author has suggested that it should be named *sobrero*, to indicate its relationship to *sobrero*. Having succeeded in re-converting "pinol" into the crystalline oxidation product, $C_{10}H_{14}O_2$, Wallach (Annalen, 259, 313; this Journal, 1890, 1117) proposes to name the latter *pinol hydrate*. This name is considered inappropriate, for the reason that it is desirable to restrict the term hydrate, as far as possible, to compounds containing so-called water of crystallisation.

The "*sobrero*" obtained from the two active modifications of *sobrero* is optically inactive, and when reconverted into *sobrero* by Wallach's method, yields the inactive form of the latter.

The proportion of crystalline oxidation product obtained is relatively very small, the greater part of the turpentine being converted into the well-known non-volatile viscid oil. Much better results would probably be obtained if the oxidation were effected under the influence of a tropical sun. As it appeared possible that the viscid oil might contain some *sobrero*, it was digested with dilute sulphuric acid and steam-distilled; a considerable amount of volatile oil was obtained, but hitherto all attempts to separate "*sobrero*" from this have failed. Notwithstanding that the greater part of the hydrocarbon is converted into products other than *sobrero*, as dextro- and levo-terebenthene are apparently oxidisable at the same rate under similar conditions, it is to be supposed that when a mixture is oxidised the crystalline product will regularly betray its origin, unless, indeed, pressure have a perceptible influence on the rate of oxidation. On oxidising American turpentine fractionally, that is to say, if when the oxidation has gone on for some time, the crystals are collected and the unoxidised oil is separated by steam-distilling and re-exposed to oxidation, a series of products is obtained, the first of which has a higher dextro-rotatory power than subsequent fractions. This is exactly what should happen if dextro-terebenthene be the chief constituent of American turpentine.

It appears not unlikely that *sobrero* may occur frequently; the authors, however, only on one occasion met any evidence of its presence. In the course of the oxidation of so-called terebene which was carried out several years ago, one of the authors had occasion to distil a large quantity of American turpentine which had been received in a wooden barrel. The most volatile portion was collected separately, and put away

in a blue Winchester quart, in a dark cellar; after a time the sides and bottom of the bottle were found to be encrusted with crystals, which were collected and recrystallised from alcohol. Only a very few grammes of the crystals were thus obtained from 10 gallons of turpentine. This substance has proved to be *inactive* sobrerol, chiefly mixed with some dextro-sobrerol.

Camphor Industry in Florida. Pharmaceutical Era, June 1, 1891; Pharm. J. 1891, 1153.

THE possibilities for the establishment of a paying industry in the line of camphor production in the Southern States, notably Florida, are very promising. Last year attention was called to the fact that the camphor tree can be profitably grown in the south, and at the recent meeting of the A.P.A. further statements to this effect were made.

Messrs. A. J. Beach and Son for some time have been experimenting at Palatka, Flo., and from them is gathered some interesting information.

For the growth of the camphor tree the preparation of the soil is very easy and simple, the tree growing with very little care after first starting. All timber should be cut and piled, not burned, and left to rot on the ground. The soil is thoroughly grubbed where the tree is to stand. The tree is planted and carefully staked to prevent the wind from swaying it when it is first set out. For three or four years the ground should be carefully worked around the trees and kept clean, the growth of timber being kept down and grubbed out, but after this time the tree will take care of itself.

The first trimming of the camphor tree is to a sufficient height for the body of the tree; after that thin out the top and shear off the outside of the top, as the young wood is the most productive of camphor.

The extraction of the gum is very simple. There is used for the purpose a still consisting of an iron pot holding about five pailfuls, and provided with a wooden cover into which is fitted a one-inch pipe leading to the condenser. The top of the kettle and cover are plastered with clay to prevent the escape of camphor vapour during the process. From the kettle the pipe turns and runs horizontally into a wooden trough about eight feet long, and then turns down and discharges into a tin can which catches any water condensing in the pipe. To charge the still the cover is removed from the kettle, which is then filled with small limbs and leaves of the camphor tree. A few quarts of water are then added to keep the leaves from burning (they burn very easily). The cover is then fitted on securely and under the kettle is placed a very small fire, and the pipe connected with the pipe in the trough, which is kept full of cold water supplied through a hose. As soon as the water produces the least steam, the camphor volatilises, passing over very rapidly. As it leaves the still it follows along until it comes in contact with the cold portion of the condenser where it condenses and sticks to the inside of the pipe in the shape of fine crude camphor. The condenser pipe is slanted a little so that any water condensed may be delivered into the can. Long before the water reaches boiling point the camphor is nearly all volatilised, but the water is allowed to form a little steam that all the camphor vapour may be driven into the condenser. Every portion of the still must be securely sealed to prevent the escape of the vapour.

To remove the gum from the condenser pipe the pipe is removed from the trough, stood upon end, and struck sharply with a hammer, when the gum will rattle out of the lower end.

Messrs. Beach and Son have carried on the camphor industry in a very small way as yet. They have only a few trees which are too small to cut much from. Nearly all the wood for experimenting has been obtained from other places. All the trees, except what were imported, were provided by the Department of Agriculture several years since, and consequently are now quite large. Other experiments are to be undertaken as fast as the wood can be procured. The yield, as nearly as can be estimated by weighing limbs and leaves, is almost 1 to 25, that is, 1 lb. of crude gum to 25 lb. of limbs and leaves.

Synthetic Musk. American Druggist; Chemist and Druggist, 1891, 868.

EXPERIMENTS by Ungerer with artificial musk show the effect of its combination with such other substances as are used in the manufacture of perfumes and toilet soaps, since these combinations furnish a more reliable test of its value than the simple method prevailing among perfumers of judging by the odour given by blotting-paper moistened with a solution or tincture. Ungerer's experiments thus far show the disappearance of the odour of synthetic musk in the presence of benzoated tallow, soapstone, chalk, cacao butter, Peru and tolu balsams, and all fatty acids. He thinks that a considerable limitation of its usefulness will result from its paralysing influence upon the olfactory nerve and its remarkable tendency to assert itself and overpower all other odours and destroy their combinations. It has an unfortunate disposition to stand alone without blending—or "marrying," as perfumers express it—with others, as is likewise the case with the amorphous precipitate called Neroline, which has caused it to be a failure in the hands of perfumers. Another fact noted by Ungerer is the absence of by-products. In the case of natural musk, the odour is almost inexhaustible, and the substance not only yields by percolation a second and third tincture, but the dried residues are available for sachets, toilet-powders, or soaps. Perfumers have come to depend largely upon this valuable property of natural musk, and look to it as a necessity for lucrative manufacturing.

PATENTS.

The Manufacture of Salicylate of Phenylidimethylpyrazolone. H. Lüttke and L. F. Riedel, Berlin, Germany. Eng. Pat. 10,432, July 5, 1890. 6d.

SIXTYFIVE quantities of phenylhydrazine, aceto-acetic ester, methyl salicylic ester, methyl alcohol, and hydriodic acid are heated in a digester to 160°–180° C. for 10–12 hours, corresponding to a pressure of 9–15 atmospheres. The resulting thick brownish mass is washed with petroleum ether, to remove the excess of methyl salicylate, the methyl alcohol distilled off, the residue left to crystallise, and purified by recrystallisation from alcohol. The salicylate forms hexagonal tables having the composition—

It is readily soluble in alcohol, benzene, and acetone, less so in ether, and very sparingly soluble in water. It melts at 91.5° C., and is decomposed by sulphuric acid with separation of salicylic acid, and by caustic soda with the separation of phenylidimethylpyrazolone. The yield of the new product amounts to 95 per cent. of the theoretical quantity. The hydriodic acid used in the preparation can be replaced by other halogen hydric acids. The salicylate can also be obtained directly from salicylic acid and phenylidimethyl pyrazolone by melting the two bodies together in presence of water. It possesses considerable antiseptic and preservative qualities, and is called "*Salipyrin*."—C. A. K.

Improvements relating to the Preparation of Hydrochlorides, Hydrobromides, or Hydriodides of Peptone and Double Salts thereof. R. Lake, London. From Kalle and Co., Biebrich, Germany. Eng. Pat. 11,189, July 17, 1890. 6d.

THE hydrochlorides, hydrobromides, and hydriodides of peptones are prepared by treating ordinary peptones or albuminoid substances like gelatin, albumen, casein, and serum with hydrochloric, hydrobromic, or hydriodic acid on the water-bath until the product is almost perfectly soluble in alcohol. The product of the reaction is then extracted with alcohol and the solution obtained evaporated to dryness in vacuo. The hydrochloride of gelatin thus prepared contains 11–12 per cent. of HCl, and by longer treatment of the gelatin with acid, a product is got almost perfectly soluble in alcohol and containing 15 per cent. of HCl. Albumen, after treatment with acid, when the mixture quickly assumes an intense violet or black colour, due to

the action of the oxygen of the air, is diluted with water and saturated with carbonate of lead, filtered, the lead in the filtrate removed by means of sulphuretted hydrogen, and the resulting solution evaporated to dryness, the residue taken up with alcohol and hydrochloric acid, and the solvent removed as in the case of gelatin. In preparing the hydrochlorides of albumen peptones the treatment with lead carbonate can be omitted.

The products thus obtained from the different raw materials have the same properties and almost the same composition. The aqueous solutions of the salts when precipitated by phosphomolybdic acid, and the precipitate decomposed by baryta, yield the free peptones, identical in every respect with the peptones obtained by the artificial digestion of all animal and pepsin substances. These decomposition products when treated with halogen acids yield first products insoluble in alcohol, which become soluble when the treatment with the acids is prolonged for some hours. The cold aqueous solutions of the salts give the best reaction, and are precipitated by phosphomolybdic acid, phosphotungstic acid, and by mercuric potassium iodide. They are not precipitated by tannic acid, by a concentrated aqueous solution of ammonium sulphate, or by potassium ferrocyanide and acetic acid. Mercuric chloride precipitates the hydrochlorides only yielding reddish yellow bodies, very insoluble in alcohol and in water.

The patent also covers methods for the preparation of double salts of the hydrochlorides of peptones with mercuric and ferric chlorides. Two mercuric chloride double salts are described, one insoluble in alcohol and containing 50 per cent. of mercuric chloride, and the other soluble in alcohol and containing 35–45 per cent. of mercuric chloride. The double ferric chloride forms yellowish hygroscopic solids readily soluble both in water and in alcohol. All the above salts are intended for medicinal purposes. —C. A. K.

Improvement in the Manufacture of Phenylmethylpyrazolone. L. Scholven and L. P. Riedel, Berlin, Germany. Eng. Pat. 11892, July 28, 1890. 6d.

SUITABLE quantities of phenylhydrazine, acetoacetic ester, sodium methyl sulphamate, sodium iodide, hydroiodic acid, and methyl alcohol are heated together in a digester for 10–12 hours at 160–185° C., corresponding to a pressure of 10–12 atmospheres. The phenylhydrazine and acetoacetic ester react to form phenylmethylpyrazolone with elimination of a molecule of water and a molecule of alcohol, whilst the sodium methyl sulphamate and sodium iodide react to form methyl iodide and sodium sulphate. The hydroiodic acid accelerates the latter reaction; the methyl alcohol added to the mixture serves as a diluent only. The methyl iodide then acts upon the phenylmethylpyrazolone to form the phenylmethylpyrazolone, which is separated from its hydroiodide by means of caustic soda and then extracted with chloroform. The chloroform solution is concentrated and treated with petroleum ether where the phenylmethylpyrazolone separates in crystals which are purified by recrystallisation from toluene, acetone, or alcohol. The oil used in the process can be quantitatively recovered as sodium iodide. The sodium methyl sulphamate may be substituted by other salts of methyl sulphonic acid, the sodium iodide by other haloid alkali salts, and the hydroiodic acid by other halogen hydracids. Also ethyl alcohol may be employed instead of methyl alcohol as the diluting liquid.

The process may be further modified by omitting the sodium iodide and employing a larger proportion of hydroiodic acid, when the latter forms methyl iodide, and acid sodium sulphate with the sodium methyl sulphamate. Methyl iodide and phenylmethylpyrazolone, formed as above from phenylhydrazine and acetoacetic ester, yield the dimethyl compound and regenerate hydroiodic acid, whilst the acid sodium sulphate acts upon the phenylmethylpyrazolone at the temperature employed in the reaction to form a sulphate of the base together with normal sodium sulphate. The free base is separated from the product of the reaction in the manner described above. —C. A. K.

Improvements in Packages for the Packing or Putting-up of Chloride of Lime, Carbonate of Ammonia, and other Volatile and Deliquescent Substances. T. Needham, Huddersfield. Eng. Pat. 19,121, November 25, 1890. 4d.
See under VII., page 642.

A Method of Utilising Waste Chips and Dust of Rhubarb Root. A. Bathoff, New York, U.S.A. Eng. Pat. 4555, March 13, 1891. 4d.

THE sound chips and sawings produced in the cutting of rhubarb root are ground or granulated, moistened, then treated with gum arabic or other suitable adhesive material, and the whole thoroughly mixed. The mass while still in a moist state is then pressed and moulded into the desired shapes, or may be spread and rolled out into a sheet and this when dried, cut up. The product thus obtained is hardly to be distinguished from the ordinary solid root; the above treatment does not impair the medicinal qualities of the rhubarb in any way, and when thus prepared it will keep in any climate and is not subject to the ravages of insects. —C. A. K.

Improvements in Methods for the Recovery and Utilisation of certain Vaporised Solvents. J. R. Whiting, New York, and W. A. Lawrence, Waterville, U.S.A. Eng. Pat. 6105, April 14th, 1891. 8d.

THIS is an improvement on a previous patent (U.S.A. Pat. 170,124 of 1875) and refers to the recovery of that portion of the solvent used in the extraction of hops which remains behind in the extractor, mechanically entangled with the leaves and woody fibre and which is not removed with the mass of the extract when the latter is drawn off. A special steam pipe and exit tube, the latter connected with a condenser, are attached to the lower part of the extractor, and after the extract has been run off, the pipe leading to this extra exit tube is opened when a portion of the residual solvent passes, by virtue of its own pressure, to the condenser. Superheated steam is then admitted into the extractor, when the remainder of the solvent is completely removed and condensed. The condensed liquid, consisting of solvent and water is collected in a suitable cylinder, provided with an overflow pipe leading to a second cylinder whereby the specifically lighter solvent is run off and the water left behind. Suitable arrangements are made for the complete condensation of any escaping vapours of the solvent. A sketch of the apparatus is given. —C. A. K.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

The Action of Light on Silver Chloride. R. Hitchcock, Amer. Chem. J. 13, 273–277.

PREVIOUS experiments by the author have shown that the action of light may cause a loss of 6.0 per cent. of the chlorine, and although the present results show a loss of 8.5 per cent., it is doubtful whether this represents the total effect, as the investigation was interrupted before its conclusion.

A number of films of silver chloride were prepared by allowing the freshly precipitated substance to deposit on microscopic cover glasses in a dark room, and after 10 days washing them by decantation. The plates were then dried and weighed and exposed to sunlight under glass for about six months, during which time they were weighed at intervals, and were found to be constantly losing weight.

Three films were found to weigh before exposure (nett) 0.02386, 0.02821, and 0.03981 respectively, and during exposure lost as follows:—

4 days.	6 days.	13 days.	5 months.	6½ months.
0.00489	0.00637	0.00700	0.00758	0.00821
0.00668	0.00620	0.00673	0.00779	0.00822
0.00614	0.00575	0.00633	0.00871	0.00929

The average loss being 8.57 per cent. of the silver chloride used.

With regard to the constitution of the altered substance, preliminary experiments show that warm dilute nitric acid dissolves from it, an amount of silver corresponding to the chlorine set free, the well-darkened chloride containing 22.5 per cent. of soluble silver—rather less than one-third of the metal present in the unaltered salt. The various films prepared as above gave a total loss in weight of 0.01393, and in their nitric acid solution silver was present in amount equal to 0.01382 of chlorine, thus seeming to prove that the action of light is merely to separate the chloride into its constituents. While the altered substance is in all probability only a mixture of silver and silver chloride, its composition approximates to the formula $(AgCl)_2Ag$.—F. H. L.

The Bisulphite Compounds of Alizarin Blue and Carulin as Sensitisers for Rays of Low Refrangibility. G. Higgins. Proc. Royal Soc. 1891, 49, 345—346.

ALIZARIN blue S possesses in a high degree sensitising properties for rays throughout the region comprised between λ 6,200 and 8,000 and it does not, like Cyanine, lower the sensitiveness to the violet and ultra violet. Plates immersed in a 1:10,000 solution of the dye and a 1 per cent. solution of ammonia give the most perfect results the day after preparation, but they deteriorate rapidly unless kept perfectly dry. Well defined lines were thus photographed in the region of the great A of the second order of the spectrum, many of which were previously not known to exist. Carulin S gives almost identical results.

It is, however, necessary that the dyes used for this purpose should be quite free from the minute cry-talisable impurities with which the commercial products are in both cases contaminated. One of the processes employed to prepare pure Alizarin blue S was to treat Alizarin blue paste with a saturated solution of sodium bisulphite and water and allow the mixture to stand in a well-stoppered vessel for 5–6 weeks, the whole being shaken daily except for the last 8 or 10 days. The filtered solution is then treated with alcohol to precipitate the excess of sodium bisulphite and water and sodium chloride added. After 7 or 8 days the dye is deposited in a crystalline form together with calcium sulphite, which latter can, owing to its insolubility, be removed by redissolving and filtering when any unchanged Alizarin blue is also left behind. The final purification is effected from alcohol containing a small percentage of water. The crystals obtained are of a deep red colour; dilute solutions are pale sherry coloured and change successively on addition of ammonia to green, magenta, purple, and finally to blue. The absorption spectrum of this blue solution is strongest in the least refrangible end of the spectrum and appears to extend into the infra-red region. Carulin S was prepared on similar lines; the pure substance is almost white. Its aqueous solution passes rapidly from pale yellow to bright green; a trace of ammonia produces an olive-green colour.—C. A. K.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

Determination of the Specific Gravity of Viscous Substances. C. Scheibler. Ber. 24, 357—358.

A METHOD for determining the specific gravity of viscous substances has recently been described by J. W. Brühl (Ber. 24, 182), but the author points out that 12 years ago he described a method for determining the specific gravity of beetroot molasses—an extremely viscous substance—at a meeting of the *Verein für die Robenzucker Industrie*, which is simpler and more accurate than that of Brühl.

The apparatus consists of a pipette having glass taps at each end, to which glass tubes are fitted by grinding. The capacity is determined by filling the pipette—including the holes of the taps—with water at any given temperature, and weighing, and the actual determination is then made as follows:—When both tubes have been adjusted, the substance is sucked up into the pipette until it is beyond the upper tap; the lower tap is then closed and its tube removed. The apparatus and its contents are then brought to the required temperature by immersing in water, after which the upper tap is closed, and the other tube detached; any of the substance adhering to the two short tubes beyond the taps is removed with water or alcohol according to its nature, and the apparatus is dried and weighed. The apparatus may be used for determining the specific gravity of all liquids, and it possesses the advantage that the determination may be made at any temperature; it may be of any desired size.—A. R. L.

Boiling Point Determinations with small Quantities of Material. A. Schleiermacher. Ber. 24, 945—947.

THE substance is introduced into the closed limb of a U-tube, which is then sufficiently filled with mercury to prevent ingress of air into the closed portion. The whole is exposed along with a thermometer in a suitable bath, and the temperature read off as soon as the mercury column is the same height in both limbs. The reading corrected for pressure is the boiling point required.

The U-tube is constructed, rendered free from air and charged with substance in the following manner:—A piece of tubing 6–8 mm. in diameter and 50 cm. long, is drawn out to a moderate capillary at one end, and this capillary at its junction with the main tube is again drawn out to a hair-like capillary 50 mm. long, and the wider portion is cut off so as to leave only a small piece; the tube is then bent, making the open end twice as long as the closed one, and allowing the tube to contract to half its diameter at the bend. The substance is then introduced, poured in if a liquid, shaken and transferred to the closed limb if a powder, and mercury is admitted so as to fill the tube within 2 cm. of the closed end; heat is then applied to the closed limb with the object firstly of melting a solid substance to enable it to collect on top of the mercury, and secondly of causing the substance to boil slightly in order to drive out any air. Mercury is now poured into the open limb so as to cause the liquid or melted solid to rise through the narrow capillary into the piece of the wider capillary at the top, the narrow capillary is then fused

together before a small blow pipe, the mercury above the bend is poured from the open limb and the apparatus is then ready for use. The small quantity of gas left or produced by fusing up the capillary so far from being detrimental is useful in accelerating boiling and preventing its becoming violent. —D. A. L.

INORGANIC CHEMISTRY.— QUALITATIVE.

New Apparatus for the Volumetric Estimation of Carbonic Anhydride, especially of Combined. G. Lunge and J. Marchewski. *Zeits. f. angew. Chem.* 1891, 229–235.

The authors review the various methods which have been proposed for the estimation of carbonic anhydride, and point out that while some are in themselves too complex and lengthy for technical purposes, others are not sufficiently accurate in their original forms, and only become so when rendered so complicated as to exclude them from these. The method to be described may be employed for the estimation of both large and small quantities, and is in

Fig. 1.

Fig. 2.

FIG. 2. THE DETERMINATION OF CARBONIC ACID.

some respects similar to that of Petterson (this Journal, 1890, 897), but much simpler, temperature and pressure corrections being unnecessary, a single boiling sufficient and the number of readings reduced to two instead of six or eight; their concomitant errors are thus partially annulled. Fig. 1 represents the apparatus one-ninth the actual size, and the decomposition flask A is shown also in Fig. 2, one quarter its actual size; for the analysis of solid substances it should not exceed a capacity of 30 cc., but for the determination of carbonic anhydride in solution or of carbon in iron, may be larger and fitted with a condenser. It has a side tube a provided with a glass stop-cock b terminating in a funnel c; its neck is 18 cm. wide, and is fitted with a well-ground hollow stopper drawn out to a capillary tube 35 cm. in length, bent at a right angle, and leading to the small side tube e (Fig. 1) of a gas volumeter on Lunge's principle (this Journal, 1890, 547). The apparatus may be employed with slight modification for measuring other gases, but when used exclusively for the estimation of carbonic anhydride as required in the cement or sugar industries, it is best constructed as shown in the figure. The top portion of the measuring tube B is a bulb of 100 cc. capacity, and is fitted with a Friedrich's stop-cock immediately under which is the 100 division, the calibration being continued to 150 down the cylindrical tube in divisions of 0.1 cc. The stop-cock f communicates with the capillary tubes e and g which run at a right angle to one another; g is connected by rubber tubing to another capillary tube provided with a stop-cock h, and communicating with the Orsat tube E which is filled with 1:3 soda-lye, and has a soda-line tube i on the open end; all the rubber joints are wired. C is the reduction tube which terminates in a fused capillary, and D the pressure tube; the latter should be 3.5 cm. wide, and both are supported by the forked clamp (shown in the figure). In adjusting the apparatus it is necessary to observe the temperature and pressure (for which it serves as its own barometer) once for all, as follows:—The gas is expelled from B by raising D, the stop-cock f is then closed, and D lowered until the distance of its mercury level is over 760 mm. from f, when a partial vacuum will be formed in the top portion of B (C) should be lowered sufficiently that the mercury sinks below the bulb in B; D is then made fast and the distance in millimetres between the two mercury levels in B and D ascertained. 1 mm. is deducted from this for the tension of mercury vapour at temperatures under 12° C., 2 mm. for 13–19°, and 3 mm. for 20–25°, and this, the pressure in millimetres is denominated h. The space which 100 cc. of dry air would occupy under these conditions is then calculated by the formula—

$$\frac{100.(273 + t) 760}{273.(h - f)}$$

in which f is the tension of aqueous vapour which may be taken approximately as (t – 2) for temperatures between 12° and 25°, thus—

$$\frac{100.(273 + t) 760}{273.(h - t + 2)}$$

The stop-cock f is next opened, the mercury in C adjusted to that division corresponding with this calculated volume, the columns in B and D being brought to the same height; a drop of water to saturate the air with moisture is then introduced into C, the capillary carefully sealed with a spirit flame, and after ascertaining that the enclosed volume of air has remained constant, the apparatus is ready for use.

A blank experiment is then made as follows:—0.1 gm. of fine aluminium or iron wire is introduced into A; B is filled with mercury by raising D, and is made to communicate with A by the stop-cock f, b being closed; D is then lowered, the stop-cock h opened, and D again raised so that the air in B is expelled through E; after this has been done on all three times the apparatus is considered sufficiently exhausted. Sufficient pure hydrochloric acid, diluted with four times its volume of boiled water, is introduced by c into A until it is three-quarters full; it is then gently heated when a brisk stream of hydrogen gas is evolved, care being taken that the pressure tube D has been sufficiently lowered. When the wire is dissolved and the

liquid has become clear, sufficient acid is run into A until it reaches the neck of the capillary *d*, and the stop-cock *f* is closed. The three tubes are adjusted to the same level, the mercury in C standing at the 100 division, and allowed to remain for 10 minutes to equalise their temperatures. During this the soda-lye is forced by blowing through *i* as far as the stop-cock *h*, which is then closed. A is now detached from the hollow stopper, washed free from acid, and prepared for the actual estimation. After adjusting, if necessary, the levels of the tubes, the volume indicated by B is read off; the cock *f* is now turned so that B communicates with *g* and *h* is opened; D is then raised, the gas driven from B into E, and again lowered; this is repeated several times. Finally the soda-lye is blown up as far as *h*, which is closed, and the tubes again brought to the same level, C standing at the 100 division. If the apparatus is quite perfect the reading indicated by B should be the same before and after the treatment with soda-lye. An error, so small that it is without influence on the result, is caused by the neglect of compressing the air contained in the capillary *g* to the standard condition before the gas is treated with soda-lye.

In the actual determination the gas is driven completely out of B by raising D, a weighed portion of the substance is introduced into A, together with sufficient aluminium wire (say 0.08 grms., 0.2 mm. in thickness), that just over 100 cc. of hydrogen are evolved. The stopper is placed in A, B is exhausted as described above, a little acid (sufficient for the decomposition of the carbonate), is introduced into A, and it is gently warmed with a spirit lamp for two minutes; after repeating the addition of acid three times more, enough is added to dissolve the aluminium, gentle warming being continued until the solution is quite clear, after which acid is run in until it reaches the capillary *d*, or better almost to the stop-cock *f*, and the remainder of the operation is conducted as in the blank experiment. The difference between the readings before and after treatment with soda-lye, gives the volume of carbonic anhydride *n* at 0° and 760 mm., and when *g* grms. of substance are taken the weight per cent. is found by the following formula:—

$$n \cdot 0.1816 \\ g$$

One experiment occupies 15–20 minutes, but during this time a fresh portion of substance can be weighed to another determination. The authors give a number of examples which show that the method gives good results.

On some Constants of Ammonia. H. von Strombeck.
Reprint from J. Franklin Inst. 1890 and 1891.

See under VII., page 637.

New Method for the Quantitative Separation of Zinc and Manganese. P. Jannasch and A. F. Gregory.
J. Prakt. Chem. 1891, 43, 402–406.

The authors avail themselves of the fact that manganese is completely precipitated by hydrogen peroxide from alkaline solution as hydrated peroxide, in order to separate this metal from zinc. The solution containing the mixed salts is acidified with dilute hydrochloric acid, at least 100 cc. of a 15–20 per cent. of ammonium chloride solution added, and then 60–100 cc. of ammonium hydrate (conc.), so that the whole is strongly alkaline. An excess of hydrogen peroxide (which must be free from barium chloride) is then added; the complete precipitation of the manganese is indicated by the sudden frothing up of the solution, due to the liberation of oxygen. The precipitated hydrate is heated on the water-bath for 10–15 minutes, filtered, washed first with boiling ammonia water and then with boiling water only, and finally dried and weighed as Mn_2O_3 as usual. The filtrate from the manganese contains the zinc which can be determined either by precipitating it as sulphide, dissolving the latter in hydrochloric acid and re-precipitating as carbonate, or the solution can be evaporated to dryness, the residue heated for an hour to 125°–150° C. in an air-bath and then

gently over the free flame so as to drive off the ammonium salts. The residue thus obtained is taken up with water, a few drops of hydrochloric acid added, the solution filtered and precipitated with sodium carbonate.

Two analyses are given in which the accuracy of the separation is satisfactorily shown.—C. A. K.

Detection of Mercury in Poisoning Cases. M. T. Lecco.
Ber. 24, 928–929.

The author calls attention to the fact that mercury is not readily dissolved by hydrochloric acid and potassium chlorate, and therefore when mixed with organic matter, as in the stomach in poisoning cases, the digestion with warm hydrochloric acid and potassium chlorate should be continued, with frequent shaking, for some hours after the organic matter has been oxidised, otherwise any mercury present would not all pass into solution, and not only could not the quantity present be determined but it might even escape detection altogether.—D. A. L.

ORGANIC CHEMISTRY.—QUALITATIVE.

Reaction of Dinitro-derivatives. J. V. Janovsky. Ber. 24, 971–972.

When 10 per cent. aqueous potash is added drop by drop to a solution of a dinitro-derivative in pure acetone, and the whole shaken and allowed to stand, a characteristic colouration develops, which is not yielded by mononitro-derivatives, and therefore serves for the detection of dinitro-derivatives in their presence. Under the stated conditions, meta-dinitrobenzene gives a red-violet solution which attains the depth and appearance of permanganate, and is changed to dark red by acetic, and yellow by hydrochloric acid; potash does not restore original colouration but produces a dark red solution.

Dinitrotoluene (1, 2—1 meta) gives a blue solution turning violet-red with acetic acid. *o*-dinitrophenalene gives a bluish-red solution, changed to cochin red by acetic acid, but completely restored by potash. Experiments are in progress to elucidate the cause of these reactions.

—D. A. L.

ORGANIC CHEMISTRY.—QUANTITATIVE.

The Use of the Calorimetric Bomb for Determining the Heat of the Combustion of Coal. M. Schenker-Kestner.
Compt. Rend. 112, 233–236.

Berthelot's calorimetric bomb is well adapted for measuring the heat of combustion of coal, and has many advantages over Favre and Silbermann's calorimeter. The author, however, draws attention to two points: (1.) That Berthelot has advised that a correction should be made for the nitric acid which is always formed during the combustion; this is measured by titrating the water used for washing out the apparatus. Now coal always contains a certain quantity of sulphur, which is converted into sulphuric acid during combustion, and, in titrating after the combustion, both acids would be present. Hence in strictly scientific investigations it would be necessary to determine beforehand the amount of sulphur present. But in industrial work this is not necessary; both corrections may be neglected, for the heat evolved owing to the formation of nitric acid scarcely amounts to 1 per 1,000; whereas the production of sulphuric acid increases the heating effect in the furnace as well as in the calorimeter. (2.) It is impossible to weigh the ash of the substance burnt in the calorimeter; it is therefore necessary to work with average samples. Berthelot advises the use of pastilles; and these do well for determining the ash. The coal is first powdered finely and then well mixed; it is made into pastilles, and a certain number of these are used for determining the ash. The limits of error are at most 4 per 1,000.

The above drawbacks are amply compensated by the ease of manipulation and the precision of the results. The author finds, however, that the heats of combustion of coal as determined by the calorimetric bomb are from 1 to 3 per cent. lower than those determined by himself and M. Menner Holffus in their earlier work with the calorimeter of Favre and Silbermann. He attributes the difference not only to the use of the new apparatus, but also to the adoption of various corrections advised by Berthelot and better methods of calorimetric work introduced by that experimenter.—D. L. J.

On the Influence exerted by the Extractive Matters in Spirituous Liquors on the Density Determinations.
C. Blauz. *Compt. Rend.* **112**, 585—588.

The astringent and colouring matters of brandies and rums do not usually amount to more than 2 to 3 grms. per litre, and do not sensibly affect the specific gravity, but saccharine matters are frequently present in much larger quantities and necessitate a resort to distillation in order to determine the amount of alcohol present. The author proposes to avoid the necessity for this distillation by making a correction for the amount of residue found on evaporation, and adding this to the amount of alcohol corresponding to the actual specific gravity of the liquid. In order to simplify this calculation, the not unreasonable assumption is made that the solid residue left on evaporation consists chiefly of sugar, and in the case where glycerol can be shown to be present in any quantity, a separate table of corrections is provided. The only determinations required are the actual specific gravity of the liquid and the amount of solid residue left on evaporation to dryness, and from these the proportion of real spirit present is calculated. As the calculation to be adopted varies somewhat with the quantity of alcohol present and with the nature of the solid residue, the conditions to be observed are somewhat complicated, and make a reference to the original article desirable.—D. L. J.

The Estimation of Acetone in Denatured Spirit.
L. Vignon. *Compt. Rend.* **112**, 873—875.

The author finds that if certain precautions be taken, acetone may be determined in denatured spirit by conversion into iodoform. It is essential to dilute the spirit largely and to employ an enormous excess of iodine. The details of the process are as follows. The alcohol to be examined, previously freed from aldehyde by Baily's method, is diluted, say, 50 times with distilled water. 5 cc. of the dilute liquid (corresponding to 0.1 cc. of alcohol) are treated with 10 cc. of biiodine soda, and then with 1 cc. of biiodine iodine, the iodoform being collected and weighed. A second test is made, using 20 cc. of soda and 10 cc. of iodine, and, lastly, the volumes of soda and iodine being doubled each time, until the results of two consecutive experiments are identical. These last figures are accepted as the correct result. (See this Journal, 1890, 659, 660.)—D. L. J.

On the Dissociation Hypothesis; on Cryoscopic Methods; and on the Freezing-Points of Aqueous Solutions of Cane-Sugar. J. Traube. *Ber.* **24**, 1321—1327.

The author has already enumerated several objections to Arrhenius' hypothesis of electrolytic dissociation (see *Ber.* **23**, 3519, 3582; **24**, 737), and he now adds to these the results of his cryoscopic investigations with aqueous solutions of cane-sugar, which he considers well adapted to demonstrate the entire untenableness of the hypothesis.

Van't Hoff, in 1887, compared the osmotic pressure at different temperatures of a 1 per cent. aqueous solution of cane-sugar, calculated from Pfeffer's observations, with that of a gas containing an equal number of molecules in the same space; in other words, he sought to demonstrate that Avogadro's law may be applied to dilute solutions. In the case of certain salts whose osmotic pressure is abnormally large, it has been necessary to assume that these were (in dilute solutions), dissociated into their ions. According to Raoult's cryoscopic determinations, however, the osmotic pressure of a 1 per cent. solution of cane-sugar is very near to that of a basic salt; the same chemist also finds that the molecular depression increases inversely as the concentration.

Arrhenius, on the other hand, finds that there is a complete regularity of the lowering of the freezing point even with the most dilute solutions of cane-sugar. The author then points out that Arrhenius' determinations do not appear to be so trustworthy as those of Raoult; for example, the former employed his thermometer as a stirrer, and neglected to determine the freezing-point of the water he used, yet he states that during an experiment the zero-point of his thermometer rose 0.015°; and as he considered this rise to be proportional to the duration of the experiment, he corrected the zero-point accordingly. But an error in the latter of 0.015° would cause a difference of 20 per cent. with the most dilute sugar solutions.

The author has obtained concordant results with the use of an open beaker, and also with Beckmann's apparatus; but the latter seems to be specially adapted to hygroscopic solutions, and the value of an air-bath appears doubtful, as errors are occasioned as much by cooling too slowly as too quickly. The beaker employed had a capacity of 125 cc.; the thermometer was graduated in divisions of 0.002°, and had a range of 0° to 5°; it could easily be read to 0.002° by the aid of a cathetometer; the stirrer was of platinum. The utmost attention was paid to the determinations of the zero-point, which were made before and after each series of experiments. By keeping the thermometer in continual vibration, a constant reading is obtained in five minutes, but when the stirring is discontinued the mercury rises 0.1° or more above the zero-point; on resuming the stirring, however, it sinks to its original position. The error in the determination of the freezing-point of water was not above 0.002°, whilst in the case of dilute solutions it was below 0.005°. Raoult employed solutions which contained weighed portions of the substance in 100 grms. of water; whilst Arrhenius used grammic molecular proportions per litre of water, and the following table contains results obtained with both:—

Cane-sugar Solutions as used by Raoult.

Grms. in 100 Grms. of Water.	Lowering of the Freezing Point = ΔT .	Molecular Depression = $\frac{\Delta T}{M}$.
20.418	0.080	0.0039
31.412	0.128	0.0041
21.265	0.120	0.0056

0.2672	0.020	0.0056
..

When the error in the determination of the freezing-point is taken as 0.01, thus four or five times greater than it really is, the results which are in agreement with those of Raoult are not altered, and the values which apply also to other organic substances serve to confirm the author's view that the osmotic coefficients of all organic compounds in sufficiently dilute solutions are the same, or nearly the same as those of many salts. The results are also in complete accord with the author's measurements of electrolytic conductivity and of capillarity, and it would seem that the dissociation of the molecular aggregates of organic compounds commences where that of salts ends. Pickering believes that in most non-electrolytes the depression is abnormally large, and that the differences between these and electrolytes are of degree only and not of kind.—A. R. L.

Estimation of Mechanical Wood Pulp in Paper.

W. Herzberg. Mitt. König. tech. Versuchs. 1891, 44—50.

No really exact method for the quantitative determination of mechanical wood pulp in paper is yet known (see also this Journal, 1890, 1068). The author describes the following methods, which are either colorimetric or gravimetric tests.

1. In Gaedicke's method (Sitz. d. polyt. Gesellsch. Berlin, 1882), a series of papers containing known quantities of mechanical wood pulp is treated with an aniline sulphate solution of a certain concentration, which produces yellow colourations. These are imitated by painting similar shades on paper, whereby the different percentages of mechanical wood pulp are indicated. Papers to be tested must be treated with the same aniline sulphate solution, and the yellow colours resulting are compared with the artificial colour scale. The degree of accuracy of this test is not stated.

2. Gottstein (Papierzeitung, 1884, 132) proposes to count under the microscope the number of wood fibres contained in a fixed area in papers of known percentages of mechanical wood pulp, after the said fibres have been rendered visible by a treatment with an alcoholic phloroglucinol solution and hydrochloric acid. This is made the basis for a comparison with the papers to be tested, which must be treated in the same way. The author is of opinion that this method can only be used if not more than about 10 per cent. of mechanical wood pulp are present, as larger quantities of wood fibres can hardly be counted with accuracy.

3. Wurster (Ber. 20, 808—810; Papierzeitung, 1887; this Journal, 1887, 565) has proposed to treat filter-paper with dimethylparaphenylenediamine. This paper is moistened with one or two drops of water or vinegar and brought in contact with the paper to be tested. The latter, if mechanical wood pulp is present, assumes a red colouration, and after being dried, the colouration is compared with a scale of standardised red colours as in Gaedicke's method. The author has found, however, that this method often gives inaccurate results.

4. Regarding Tech's method, the author confirms the view of Benedikt and Bamberger (compare this Journal, 1891, 576), but has not sufficient data to base an opinion of its accuracy.

5. By A. Müller's method (A. Müller, Die qualitative und quantitative Bestimmung des Holzschliffs im Papier), the

paper to be treated is moistened with a solution of salt, and then treated for 10 minutes with a cupraammonium solution of a certain concentration. The mechanical wood pulp is hereby little affected, whilst the pure cellulose fibres are dissolved. The loss is ascertained gravimetrically. Möller himself states that the errors of this method are 3 per cent. or more, and the author considers it unsuitable for practical purposes.

6. With reference to Godfrey's and Coulon's method, see this Journal, 1891, 576. The author is of opinion that this is the most accurate of all existing methods, and that modified may become a test of technical importance.

7. As regards the new method of Benedikt and Bamberger (see this Journal, 1891, 576—577), the author remarks that it is not less tedious than Godfrey's method, and probably in various details more difficult, e.g., in ascertaining from what sort of wood the mechanical wood pulp has been manufactured.

The author himself, for technical purposes, uses a colorimetric method similar to those of Gaedicke and Wurster, but without employing an artificial colour scale. Any reagents for mechanical wood pulp, such as phloroglucinol, aniline sulphate, &c., may be employed in varying concentrations, and for comparison a complete set of papers of different thicknesses and known percentages of mechanical wood pulp is used. A preliminary test is made with phloroglucinol to see whether the paper in question contains little or much mechanical wood pulp, in order to make a selection among the necessary comparison papers. Then these, as well as the paper to be tested, are cut into small pieces of about 1.25 in. square and soaked from two to five minutes in a solution of phloroglucinol or any other reagent. The colouration then indicates to which of the comparison papers of known percentage of mechanical wood pulp the paper to be tested corresponds. The author recommends that the papers be examined in transmitted as well as reflected light. This method is stated to be more accurate than the other colorimetric tests, and is of special value for papers which contain but a small quantity of mechanical wood pulp, e.g., less than 10 per cent. It is of course unsuitable for coloured papers, but may be used in cases where the colour can be easily removed or destroyed, e.g., by dilute acids, alkalis, alcohol, &c. It must be mentioned that it is at present difficult to obtain a proper set of standard papers for comparison. The more complete such a collection is, the more accurate will be the result of the test.

The microscopic examination of the papers to be tested materially assists all the methods above described, and the author recommends comparisons with papers or paper pulps the composition of which is known. He does not, however, recommend the counting of fibres under the microscope, but prefers to judge from the general microscopic appearance. The before-mentioned preliminary test with phloroglucinol will be found useful also for the microscopical examination.—H. S.

Determination of Resin Oil in Mineral and Fatty Oils.

Holde. Mitt. König. tech. Versuchs. 1891, 51—52.

The following table contains the reactions which are characteristic and requisite for the detection of resin oil in mineral and fatty oils:—

—	Appearance.	Specific Gravity at 15° C.	Indices of Refraction at about 18° C.	Solubility in Alcohol at ordinary Temperatures. (1 Vol. of Oil to 2 Vols. of Alcohol.)	Colour when vigorously shaken with Sulphuric Acid of 1.621 Sp. Gr.	Morawsky's Test with Anhydrous Acetic Acid and Sulphuric Acid of 1.530 Sp. Gr.
Resin oils	Yellow or yellowish-brown. Smell and taste of resin.	0.97—0.98	1.535—1.549	50—75 per cent. volumetrically.	Red.	Violet red or red.
Mineral oils	Different shades, from yellow to black. Fluorescence.	0.89—0.92	1.500—1.507 (light-coloured mineral oils only).	2—15 per cent. volumetrically.	Yellow or brown.	No characteristic colour, different shades from green to brown or red.
Rape and olive oils	Yellow or green. Characteristic smell.	0.913—0.917	Rape oils: 1.4725—1.4749 Olive oils: 1.4680—1.4696	Yellow.	No characteristic colour, different shades from green to brown.

If, however, only small quantities of resin oils are supposed to be present, or if mineral oils of dark colours have to be tested, the alcoholic extract mentioned in this table has to be evaporated, and the residue, if resin oil be present, will show all the reactions as well as the characteristic smell and taste of resin oil. (Compare this Journal, 1889, 572—573; 1890, 112, 119; 1891, 166, 276.)—H. L.

ANALYTICAL AND SCIENTIFIC NOTES.

The Action of Heated Carbonic Oxide. Berthelot, Compt. Rend. 112, 594—597.

On heating carbonic oxide to temperatures varying from 500 to a bright red-heat, it is found that a small amount of decomposition sets in, carbonic acid being formed. This decomposition, however, does not increase in amount as the temperature rises, the only difference being that at the lower temperatures no free carbon is formed. The action takes place even when traces of moisture and other impurities are rigorously excluded. For these reasons, the decomposition cannot be of as simple a nature as is usually represented, but is probably of the nature of a polymerisation, carbonic oxide being a tetratomic anhydride, thus—

This suboxide is apparently permanent at temperatures of 500—550°, but at a red heat is split up into free carbon.

—F. H. L.

A Reaction of Carbonic Oxide. Berthelot, Compt. Rend. 112, 597.

If a few bubbles of carbonic oxide are passed into a weak and cold solution of ammoniacal silver nitrate, the liquid immediately assumes a brown colour, and at the boiling point the silver is quickly reduced. The action takes place also with an aqueous solution of the gas and is extremely delicate, not being hindered even by the admixture of a large amount of air. This property of carbonic oxide is the more interesting, seeing that the solution is not reduced by alkaline formates, nor by pure hydrogen.—F. H. L.

New Books.

THE CHEMISTRY OF ILLUMINATING GAS. By NORRIS H. HEMPHREYS, Assoc. M. Inst., C.E., F.C.S., &c. London: Walter King, Office of "The Journal of Gas Lighting," No. 11, Bolt Court, Fleet Street, E.C. 1891.

Octavo volume, bound in cloth, price 6s. It comprises Preface stating that the matter of the book consists mainly of articles written for the *Journal of Gas Lighting*, and published therein. The subject-matter fills 248 pages, is preceded by a Table of Contents, and followed by a carefully arranged Alphabetical Index. The text is sub-divided as follows:—Introduction. CHAP. I. Relative cost of Light from Gas, Oil, and Candles. II. Products of Combustion. III. The Sulphur Question. IV. The Composition of Illuminating Gas. V. Water Gas. VI. Various Gas-making Processes. VII. Oil Gas. VIII. Properties of Fluid Hydrocarbons. IX. Tar for Gas Making. X. Destructive Distillation. XI. Condensation. XII. Purification.

A FEW NOTES ON VARNISHES AND FOSSIL RESINS. By R. INGHAM CLARK, F.R.S., F.R.G.S., &c. Illustrated by JAMES WEST. London: Chas. Lotts and Co., 3, Royal Exchange.

Eighteen bound quarto volume, price 10s. 6d. The style is antique, though the type used for the general subject

matter is the ordinary. The work is profusely and elegantly illustrated and the division of the matter is into two parts, viz., PART I. VARNISH; and PART II. RESINS. Under these two divisions the subject is sub-divided somewhat as follows:—

PART I. VARNISH.—Definition; Etymology; Early Origin, &c. Growth and Commercial Extension. Japanese Lacquer; Japanese Lacquer unsuitable for European use; Probable large future consumption of European Varnishes in Japan and China. Modern Varnish making. Amber impracticable for Varnish purposes. Literature; Continental Works. Recent extension of the Trade. High esteem of English Varnish.

PART II. RESINS.—Amber. Animis. Madagascar Animis. Demerara Animis. Copals. Sierra Leone Copals. Acera, Congo, Gaboon, and Loango Copals. South American Copals. Manila Copals. Kauri. Gum Damar. Mastie. Bastard Animis and Copals.

TABELLÄRISCHE UEBERSICHT DER KÜNSTLICHEN ORGANISCHEN FARBSTOFFE. VON GUSTAV SCHULTZ und PAUL JETTS. Zweite verbesserte und vermehrte Auflage. Herausgegeben von GUSTAV SCHULTZ, 1891. Berlin: R. Gaertner's Verlagsbuchhandlung, Hermann Heyfelder, Schönebergerstrasse 26, S.W. London: H. Grevel and Co., 33, King Street, Covent Garden.

This admirable work, a model of useful condensation and classification of a wide and diffuse subject, is dedicated to Professor A. W. Hofmann on the occasion of his 70th birthday as a mark of high esteem and veneration by the author. It is a quarto volume bound in cloth and gilt, and containing besides the Dedication already referred to, Preface to the first edition, a short one to the second edition, in which it is claimed that the present edition contains over 100 new colouring matters added to those described in the first edition, Table of Contents and List of Abbreviations. The tabulated Review covers no less than 723 pages, and is followed by an Alphabetical Index, and the work ends with a small list of Corrigenda. In the tabulated list of Colours no less than 392 of these are referred to.

The following Classes of Colours are described in this work:—I. Nitrofarbstoffe. II. Azoxyfarbstoffe. III. Hydrazonfarbstoffe. IV. Azofarbstoffe. V. Nitrosfarbstoffe. Chinovimfarbstoffe. VI. Oxyketonfarbstoffe. VII. Diphenylmethanfarbstoffe. VIII. Triphenylmethanfarbstoffe. IX. Indophenole. X. Oxazine und Thiazine. XI. Azine. XII. Künstlicher Indigo. XIII. Chinolinfarbstoffe. XIV. Acridinfarbstoffe. XV. Thiobenzenylfarbstoffe. XVI. Farbstoffe von unbekannter Constitution. The price of the work is 14s.

ENCYCLOPÆDIC ENGLISH-GERMAN AND GERMAN-ENGLISH DICTIONARY. Uniform in plan and arrangement with SACHS VILHART'S French-German and German-French Dictionary. Giving the Pronunciation according to the phonetic system employed in the method of Toussaint-Langenscheidt. English-German. By Professor Dr. ER. MEIER. Unabridged Edition. Part 2. Berlin: Langenscheidt'sche Verlagsbuchhandlung (Prof. G. Langenscheidt), 1891. New York: The International News Company. London: H. Grevel and Co., 33, King Street, Covent Garden.

PART 2 is now issued, in paper cover, large 8vo size. It extends from ALO to BAN. Price 1s. 6d. It may be added that this great work includes technical terms; in the words of the compiler it is "For the general public, and consequently for all classes of society, the man of science no less than the man of the people." It is written "To serve the great Anglo-Germanic family of nations, branches of which are now established in all parts of the world, as a practical means of understanding each other." The Preface alone of this work is a study, and indeed a wonder, of condensed and well-classified information.

Trade Report.

(From the Board of Trade Journal.)

TARIFF CHANGES AND CUSTOMS REGULATIONS.

NORWAY.

Tariff Changes.

Note.—Krone = 100 Öre = 1s. 1½d. Kilogr. = 2·204 lb. avoirdupois. Litre = 0·22 imperial gallon.

Mr. T. Michell, Her Majesty's Consul General at Christiania, in a report to the Foreign Office, dated the 19th June last, encloses the following list of the principal alterations made in the Norwegian tariff during the present session of the Storting, and which came into force on the 1st July:—

Tariff No.	Articles.	New Duty.	Old Duty.
		Kr. Öre.	Kr. Öre.
46—52	Spirit of every kind:— When by admixture spirits shall be made unfit to be prepared for drink, or if the Customs Department shall be satisfied that the spirit is guaranteed against use as a drink, they may charge a lower duty, viz.:— (a.) Spirits..... Litre 0·10 (b.) Spirit varnish..... Kilogr. 0·10	Free. 2·00	
76—79	Vinegar and acetic acid:— (1.) In casks:— (a.) Not over 10 per cent. of acid:— Up to and including 31st December 1891. Kilogr. 0·16 From 1st January 1892. „ 0·05 (b.) Over 10 per cent. of acid:— Up to and including 31st December 1891. „ 1·60 From 1st January 1892. „ 0·10 Tare under 1 (a) and (b) 16 per cent.:— (2.) In bottles or jars:— (a.) Under 10 per cent. of acid:— Up to and including 31st December 1891. Litre 0·17 From 1st January 1892. „ 0·10 (b.) Over 10 per cent. of acid:— Up to and including 31st December 1891. „ 1·60 From 1st January 1892. „ 0·10	0·16 1·60 0·17 1·60	
357	Oils. I.:— (c.) Castor oil (<i>oleum ricini</i>) „ 0·01	Free.	
358	Oils. I.:— (d.) Colouring for butter „ 0·04	Free.	
360	Oils. II.:— (a.) Camphine, paraffin, photogen, wood oil, and similar illuminating oils, American mineral oil and petroleum. „ 0·05	0·10	
450	Stone, and manufactures of:— (2.) Emery..... Free	0·07	
356	Sugar and syrup:— Sugar of every kind, including dissolved and other liquid sugar (and therefore also juice in which the sugar has been separated) which cannot be classified under ordinary syrup or molasses; grape and starch sugar and grape and starch syrup. Kilogr. 0·30	0·10	

MOROCCO.

Export of Essences.

Note.—The real = 2½d. about. Quintal = 220·4 lb. avoirdupois.

Mr. H. E. White, Her Majesty's Chargé d'Affaires at Tangiers, in a despatch to the Foreign Office dated the 30th May, transmits copy of circular letter, together with its enclosure, addressed by the French Minister to the representatives of foreign powers at Tangiers, announcing that he had obtained from the Sultan permission for the distillation and exportation of the following essences on payment of the undermentioned duties:—

Caraway essence, 100 reals per quintal; thyme essence, 40 reals per quintal; peppermint essence, 40 reals per quintal; wormwood essence, 100 reals per quintal; arbutus essence, 20 reals per quintal.

Distillation can only take place in towns such as ports, to the exclusion of the country districts.

Merchants must confine themselves to the distillation of the five products mentioned above, to the exclusion of all others. Every other essence found in their possession will be treated as contraband goods, and confiscated.

SWITZERLAND.

Classification of Articles in Customs Tariff.

Note.—Quintal = 220·4 lb. avoirdupois. Franc = 9s. 4d.

The following decisions affecting the classification of articles in the Swiss Customs tariff were given by the Swiss Customs authorities in the month of April last:—

“Lux luxuria” (waxing for furniture).—Category 9. Duty, 10 francs per quintal. This product when made with alcohol pays further a monopoly tax (*finance de monopole*) of 3·50 frs. per quintal gross weight.

Acetone (*spiritus pyroaceticus*, spirits of pyroigneous vinegar).—Category 17. Duty, 1 fr. per quintal.

Explosives of all kinds, such as melinite bombs, &c., loaded.—Category 20. Duty, 50 frs. per quintal.

Alloys of aluminium, hammered, rolled, drawn, in bars, sheet, tubes, wire.—Category 137. Duty, 3 frs. per quintal.

UNITED STATES.

Customs Decisions.

The following decisions respecting the construction to be given to Acts of Congress relating to the classification of articles in the Customs tariff, and the application of the Customs laws of the United States, have recently been given by the Customs authorities in that country:—

Celluloid tags or labels to be used in designating the names of various plants are dutiable at 60 cents a pound and 25 per cent. *ad valorem* under the provision of paragraph 21, Act of October 1890, for finished articles made of collodion.

Chloral hydrate is dutiable under paragraph 74, N. T., as a “medicinal preparation” of which alcohol is a component part, or in the preparation of which alcohol is used, not specially provided for in this Act.

Bicarbonate of potash is dutiable as a chemical salt not specially provided for, under the Act of the 1st October 1890, at 25 per cent. *ad valorem* under paragraph 76 of said Act.

Resorcine being a preparation of coal tar, not a colour or dye, and so commercially known, is specifically provided for in paragraph 19, N.T., and subject to duty at 20 per cent. *ad valorem*.

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

MINING IN OREGON.

Mr. Vice-Consul Laidlaw supplies the following particulars of mining in Oregon:—

Copper is found in Baker and Josephine counties, but the deposits are not worked. Chrome ore is found in Southern

Or 200, and nickel in Douglas, Josephine and Jackson counties. Manganese has been found in quantity in Columbia county. There are coal-fields in Coos, Columbia, Clatsop, and Washington counties, but none of the deposits have been worked, except those of Coos bay, which have been worked for years and yield a very superior quality of coal.

About five miles north of this port, at Oswego, large deposits of brown hematite are found, the thickness of the vein varying from 6 ft. to 15 ft. These mines have been worked for some years by the Oregon Iron and Steel Company. The ore analyses are as under:—Metallic iron, 44.71 per cent.; phosphorus, 0.666 per cent.; phosphorus in 100 parts iron, 1.490 per cent. There are other deposits of similar ore in other portions of the State, but they are not worked. (No. 906, *Foreign Office Annual Series*.)

GENERAL TRADE NOTES.

PETROLEUM PRODUCTION IN THE UNITED STATES.

A bulletin on the production of petroleum in the United States has been issued by the Division of Mines and Mining of the Census Office. This shows that petroleum was produced in 14 States in 1889, namely, Pennsylvania, New York, Ohio, West Virginia, Colorado, California, Indiana, Kentucky, Illinois, Kansas, and Texas. The total production is shown to be 31,820,306 barrels, valued at 26,551,652 dollars. It also shows the annual production of petroleum in the United States from 1859 to 1889 inclusive.

The returns show that of the total product of petroleum 109,841 barrels were disposed of for lubricating, 12,330,813 for fuel and 22,379,692 for illuminating purposes. Nearly the entire amount produced in California, Indiana, and Ohio, was used for fuel, while nearly the entire amount produced in Colorado, New York, Pennsylvania, and West Virginia was used for illuminating purposes.

SPANISH IMPORTS OF ALCOHOL.

The *Monde Economique* quotes from official statistics recently published to the effect that the export of German alcohol to Spain has within the last few years diminished very largely. In 1882 the exports of this product only totalled 189,000 metric quintals, whilst they increased for each of the years 1883, 1884, 1885, and 1886, to 248,000, 333,000, 510,000, and 512,000 metric quintals, respectively. For 1887 there were only registered 274,000 metric quintals, 142,000 for 1888, and 138,000 for 1889. This diminution should, says the *Monde Economique*, enable French producers to regain in Spain their old ascendancy.

THE MINOR MINERAL INDUSTRIES OF THE WEST.

Much attention is now being given in the Rocky Mountain States to the mining of many of the minor, but still important minerals. In nearly all of these States there are extensive deposits of useful and valuable minerals, the existence of which has been known for many years, but which have hitherto been comparatively neglected, the greater profit possible in gold and silver mining being more attractive to mining men, while unfamiliarity with the uses and markets of the minor minerals has caused them to be passed over in many instances by prospectors. The fact that they are now exciting more interest is evidence of the business-like manner in which the mining industry in the West at present is being conducted.

Several of these comparatively new undertakings have attained considerable magnitude. Thus, the stone quarrying industry, commenced to meet local demands, has become an important source of wealth to a number of the States, Colorado, for instance, shipping its product to all parts of the country. A recent bulletin issued by the Census Office on the sandstone quarrying industry in the United States showed that Colorado had risen during the past decade to the third position in the list of States producing this stone. The petroleum industry in Colorado and California is of much importance and is growing, the product having increased in Colorado from 297,642 barrels in 1888 to 316,476 barrels in 1889. In California, however, there was a considerable decrease during the same time.

Extensive deposits of borax were discovered in California and Nevada many years ago; and in the early days upon the Comstock lode, when there was a demand for this chemical for certain milling processes in use there, the marshes were worked upon a small scale. Some time afterwards it was found that the product, which was of excellent quality, could be shipped to England at a profit, and a business of considerable importance was thus established. The borax marshes of California are now being systematically worked, and the proprietary companies are paying substantial dividends.

The large deposits of asphaltum and kindred minerals in California and Utah are now attracting considerable attention, as is shown by the fact that their production has grown from 4,000 tons in 1887 to 53,800 tons in 1888 and 51,735 tons in 1889. The asphaltum minerals of California and Utah are of widely different kinds, ranging from the semi-liquid breccia and hard gilsonite, suitable for the manufacture of varnishes, to bituminous rock used in concrete; much of the latter is of excellent quality, comparing favourably with the asphaltum of Trinidad. This industry has not yet attained such large proportions in Utah as in California, the deposits in the territory being situated far from railways. They are of great extent, however, and several companies have been organised during the present year to undertake their development.

Utah, whose mineral resources are extremely diverse in character, also contains large beds of sulphur, which have been worked somewhat extensively although allowed to lie idle during the past two years, but we are informed these mines are about to be reopened. A recent discovery of nitre has been made in the territory.

Nevada also contains beds of sulphur, which are now being worked upon a small scale. Nickel exists in the State, and a small amount has been produced, but these deposits do not seem to be of great importance. A more promising industry has been established in Nevada during the present year in the mining of antimony ore, large veins of which have been found. One of these was acquired about five months ago by an English company, which proposes to operate it energetically, and has already commenced shipment of its products to Liverpool. The ore is undoubtedly of excellent quality, and it would seem that the industry might be profitably prosecuted.—*Eng. and Min. Journal*.

THE SALT TRADE OF BRITISH INDIA.

A significant feature in the returns of the salt trade of India for the past year is the steadily increasing import of crushed salt from Hamburg, Aden, and the Sulkea Golahs. The *Englishman* of Calcutta says that in the course of three years the amount of Liverpool salt passing through the Calcutta Customs has decreased by about 17 per cent., while the Hamburg imports have increased by 700 per cent. In 1888 no salt was received from Aden or the Sulkea Golahs; in 1890 the import amounted to nearly a lakh and a half of maunds. In the opinion of the collector, the Hamburg salt, which is steadily winning a market, will eventually be displaced in its turn by the crushed kurkutch of Aden and Golah. At present, however, the chief difficulty with which both varieties of crushed salt have to contend in their competition with Liverpool is that of bulk. In the wholesale trade this difficulty does not arise, since salt is bought only by weight; but the native consumer is accustomed to purchase in small quantities and by measure, usually by the handful. Since Liverpool salt is bulk for bulk tighter than its rivals, the retailer can afford to give a larger handful; and some time must elapse before the consumer can be brought to see that a small handful of kurkutch is equivalent in salting property to a considerably greater measure of the Liverpool product. The rapid introduction of kurkutch is due to the fact that the dealer can afford at present prices to undersell the lighter variety, not only weight for weight, but bulk for bulk.

THE PLATINUM SPECULATION.

The Siberian Commercial Bank at Iekaterinenburg announces its readiness to advance holders of platinum

metal from 300 to 371 roubles per kilo. (= about 16*l.* to 19*l.* per lb.) on their stocks. The object of this announcement is said to be to counteract the schemes of English speculators who have organised a strong movement for the depression of the platinum prices.—*Chemist and Druggist.*

GERMAN PHOTOGRAPHIC DRY PLATES.

The annual report of the Frankfort-on-the-Main Chamber of Commerce complains of the adverse influence of the high Customs duties on glass upon the German industry of photographic dry plates. Principal among the raw materials of that industry, which is a considerable one in Germany, are nitrate of silver and window glass. Silver has considerably advanced in price recently, and window glass has likewise risen. Dry plate manufacturers can use only English, or, in case of need, Belgian glass. German glass is unsuitable, because it is too unequal in thickness and not sufficiently straight. But the German glass manufacturers are protected by a high duty, and hence they do not take the trouble to produce as good glass as the foreign makers. In consequence of this, the price of glass in England has advanced 50 per cent., which difference has to come out of the pockets of the German dry plate manufacturers, who are already heavily handicapped in neutral markets by the great expansion of the dry-plate industry in England and Belgium. On these grounds the Frankfort Chamber of Commerce claims a reduction in the glass duties. It should be added that the Frankfort Chamber of Commerce is a body of pronounced free trade views, and that it is scarcely correct to describe the advance in the English glass prices merely or chiefly to the necessities of the German photographic dry-plate makers.—*Ibid.*

RECENT TRADE BLUE BOOKS.

*United States Tariff. Return respecting the Customs Tariff of the United States, including a Tabular Statement comparing the Rates of Import Duty now levied with those which were in existence previous to the 1st October 1890, the "McKinley Administrative Act," and other documents. (C.—6381.) Price 1*s.**

This is a statement issued by the Commercial Department of the Board of Trade, showing in a comparative form the rates of import duty levied under the present and the previous Customs tariffs of the United States. It contains also the remaining provisions of the Tariff Act of the 1st October 1890, in full, as well as the text of the McKinley Administrative Act of the 10th of June 1890, together with the regulations and Treasury instructions to officers of Customs under the Act.

*Mines and Minerals. Mineral Statistics of the United Kingdom of Great Britain and Ireland, with the Isle of Man, for the Year 1890. (C.—6364.) Price 1*s.* 4½*d.**

This is a return prepared under the direction of the Home Office. In the introduction it is stated that the present volume contains an account of the quantity and value of all minerals wrought in mines, the value of all minerals obtained from openworks, brineworks, &c.; a table of the mines inspection districts, with the names and addresses of inspectors of mines, assistant inspectors, secretaries to boards for examinations, and the clerk of mineral statistics; also an appendix showing the production of minerals in the British colonies and possessions.

The sources from which minerals are obtained in the United Kingdom are classed under three heads:—

1. Mines under the Coal Mines Regulation Act.
2. Mines under the Metalliferous Mines Regulation Act.
3. Openworks, brineworks, &c. which are not comprised by these Acts.

The introduction further states that an annual return is required to be sent from every mine to the inspector for the district specifying, under the Coal Mines Act, the quantity of minerals wrought during the year, and, under the Metalliferous Mines Act, the quantity of minerals dressed, and of the undressed minerals sold, treated, or used during the year.

The statistics of minerals wrought from mines are prepared from these statutory returns.

The statistics of minerals obtained from openworks, brineworks, &c., are obtained from information furnished to the inspectors of mines and to the Home Office, the total number of persons employed at openworks being taken from the census returns.

The exports and imports of each of the principal minerals, furnished by the Board of Customs, are given after the tables of production, and in several cases information as to distribution, supplied by railway and navigation companies, is added.

Lists of smelters of the principal metallic ores follow the export and import tables, and, in the case of iron, the make of pig-iron and the quantity of ore and coal used are given for each county, from statistics furnished to the Home Office by the owners of blast furnaces.

The general summary shows that coal, iron ore, and stone are the most important minerals worked in the United Kingdom.

An appendix is added showing the production of minerals in the British colonies and possessions, compiled from official reports and other sources.

*British and Foreign Spirits. Report 219. Price 1*s.* 5½*d.**

This is the report of the Select Committee of the House of Commons appointed to consider whether, on grounds of public health, it is desirable that certain classes of spirits, British and foreign, should be kept in bond for a definite period before they are allowed to pass into consumption, and to inquire into the system of blending British and foreign spirits in or out of bond, and into the propriety of applying the Sale of Food and Drugs Act and the Merchandise Marks Act to the case of British and foreign spirits and mixtures of British and foreign spirits, and also into the sale of ether as an intoxicant.

The Committee in their present report, after reviewing the production and consumption of spirits, their distillation, together with their definition and classification, character and purity, state, with regard to the latter point, that they arranged with the Inland Revenue that about 50 samples of spirits should be collected from public-houses, shebeens, and fairs in various parts of the country, to ascertain whether adulterations of a pernicious character might be put into them by the retailer before being given out to the customers. It is pleasing to say that not a single case of such adulteration was found. They varied greatly in strength, being from 14 to 30 under proof, but the spirit was normal.

With regard to the blending of spirits, the Committee state that they do not recommend any increased restrictions on blending spirits. The trade has now assumed large proportions, and it is the object of blending to meet the tastes and wants of the public, both in regard to quality and price. The addition of patent-still spirit, even when it contains a very small amount of by-products, may be viewed rather as a dilution than an adulteration, and, as in the case of the addition of water, is a legal act within the limits of strength regulating the sale of spirits.

With regard to the bonding of spirits, the Committee state that their general conclusion from the evidence submitted is that compulsory bonding of all spirits for a certain period is unnecessary, and would harass trade.

With regard to the effect of spirits on public health the Committee is of opinion that as the public show a marked preference for old spirits, which the trade find more profitable, and as the practice has arisen of blending whiskies with patent spirits, to fit them for earlier consumption, it is not desirable to pass any compulsory law in regard to age, especially as the general feeling of the trade is that such an obligation would harass commerce and be an unfair burden on particular classes of spirits.

POTASSIUM SALTS.

For some time past the "Georg" Brown Coal Works Company has been making deep borings for rock salt at Aschersleben, and during the past year has discovered

layers of rock salt, for which the company has obtained the right of working. A discovery of potassium salts has recently been made at a depth of 1,050 ft., and some works have been erected there. *Industries.*

PAPEES OF INTEREST TO TECHNOLOGISTS AND MANUFACTURERS.

Esparto..... "	10,543	20,803	89,278	100,521
Pulp of wood..... "	10,806	16,756	61,329	81,836
Rosin..... Cwt.	216,057	269,187	50,000	69,118
Tallow and stearin..... "	161,122	143,655	191,306	185,682
Tar..... Barrels	6,563	3,918	6,396	2,394
Wood:—				
Hewn..... Loads	180,229	236,281	433,100	442,566
Sawn..... "	509,013	569,518	1,182,411	1,136,355
Staves..... "	18,981	18,435	79,533	61,285
Mahogany..... Tons	2,177	4,362	18,618	40,258
Other articles... Value £	812,462	899,795
Total value.....	3,663,124	3,963,939

Besides the above, drugs to the value of 77,567*l.* were imported as against 68,704*l.* in June 1890.

IMPORTS OF CHEMICALS AND DYESTUFFS FOR MONTH
ENDING 30TH JUNE.

Articles.	Quantities.		Values.	
	1890.	1891.	1890.	1891.
Alkali..... Cwt.	4,006	7,549	£ 3,667	£ 4,816
Bark (tanners, &c.) ..	93,131	53,948	16,574	27,190
Brimstone	64,494	58,839	14,136	17,710
Chemicals..... Value £	132,261	121,153
Cochineal	700	545	4,368	3,377

Other articles .. Value £	80,488	80,970
Total value	3,775,311	4,225,594

EXPORTS OF DRUGS AND CHEMICALS FOR MONTH ENDING
30TH JUNE.

Articles.	Quantities.		Values.	
	1890.	1891.	1890.	1891.
Alkali..... Cwt.	483,176	519,834	£ 157,348	£ 196,831
Bleaching materials ..	109,430	134,915	30,820	46,618
Chemical manures. Tons	24,788	28,738	162,466	177,313
Medicines..... Value £	88,220	88,996
Other articles	233,656	251,346
Total value	792,528	761,104

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

10,181. I. Thorp and J. Birtwistle. *See Class XVIII., B.*
10,229. E. Theisen. Improved method of and apparatus for effecting the condensation of steam and other condensable vapours. June 17.

10,411. W. Bergius. *See Class XVII.*

10,456. H. L. Callendar. Improvements in pressure gauges, suitable especially as piezometers, barometers, thermometers, and the like. June 19.

10,516. The Manchester Oxygen (Brin's Patent) Co., Ltd., and W. M. Jackson. Improvements in and in the mode of utilising the pressure in cylinders or reservoirs of compressed gases in the application or employment of such gases. June 20.

10,599. E. F. Bourdil. Improvements in apparatus for atomising or pulverising liquids. June 22.

10,616. E. Theisen. Improvements in apparatus for condensing steam and other condensible vapours. June 22.

10,651. G. Glydon. Regulators or governors for compressed gases or other fluids. June 23.

10,659. H. Wilson. *See Class XVII.*

10,738. C. H. Haubold. A centrifugal machine for incorporating together various substances. Complete Specification. June 24.

10,752. G. Grondal. Improved regenerative gas furnace. Complete Specification. June 24.

10,771. W. J. Tranter and S. Hale. An improved compound for preventing incrustation and corrosion in steam and other hot water boilers. June 24.

10,833. A. W. Ellis. An improved stand for chemical or other purposes. June 25.

10,902. J. F. Braidwood. *See Class II.*

11,041. R. Harvey. Improvements in and relating to evaporating apparatus. June 29.

11,043. G. W. Miller. Improvements in faucets for measuring fluids. Complete Specification. Filed June 29. Date applied for January 13th, 1891, being date of application in United States.

11,210. L. H. Armour. *See Class II.*

11,353. W. O. Taylor. The oxidising retort furnace. July 1.

11,443. B. D. Healey. Improvements in cauldrons for melting pitch and fatty substances. July 6.

11,556. C. F. Parsons. *See Class VIII.*

11,640. A. G. Southby and F. D. Blyth. Improvements in apparatus for making ice, refrigerating, evaporating, and deaerating. July 8.

11,690. J. A. Burley. From P. A. Mallet and A. T. Lagnez, France. Improvements in analysing columns. July 9.

11,691. J. A. Burley. From A. T. Lagnez, France. Improvements in apparatus for the automatic regulation of pressures and temperatures. July 9.

11,779. H. L. Callendar. Improvements in thermometers and pyrometers. July 11.

COMPLETE SPECIFICATIONS ACCEPTED.*

1890.

4532. E. G. Lawrence.—From S. Pick. *See Class VII.*

10,721. W. L. Wise.—From Solvay and Co. Method and means for charging materials into apparatus such as cupolas, blast furnaces, limekilns, scrubbers, and absorption-towers. June 21.

11,711. D. Rylands and R. Morant. Glass-lined tubing. June 17.

12,535. E. Barlow and R. Cunliffe. Apparatus for drying, calcining, and evaporating. July 15.

13,322. R. Harburn. Apparatus for evaporating and distilling liquids. July 1.

13,390. J. Batten. Regenerating furnaces. July 1.

14,101. H. C. Shaw. Apparatus for heating boilers, evaporating pans, &c. July 15.

18,099. T. P. Hinde. *See Class XVII.*

18,596. E. J. Hardy. Production of cold, and apparatus therefor. July 8.

1891.

2916. G. Goodlet. Apparatus for compressing and accumulating fluids. July 1.

7187. S. M. Lillie. Evaporating apparatus. July 8.

7704. H. Burgess and C. D. Davis. Vacuum evaporating apparatus. July 15.

8517. W. H. Beck.—From G. Moreau. *See Class II.*

8809. W. J. Mirreles.—From H. T. Varyan. Evaporating and distilling apparatus. July 1.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

10,452. E. Rischgitz and The Patent Mining and Financial Trust, Ltd. Improvements relating to the treatment of peat. June 19.

10,515. T. Reynolds. Improvements in clay and asbestos fire-bricks for use in gas fires. June 20.

10,667. F. Fanta. A new self-acting apparatus for the automatic production of oxygen. June 23.

10,866. F. J. Jones. An improvement in furnaces for reheating gases used in coke making. June 25.

10,902. J. F. Braidwood. Improvements in apparatus for charging retorts for the manufacture of gas and for other like purposes. June 26.

10,918. J. C. Chandler. Improvements in apparatus for washing or scrubbing gas. June 26.

11,210. L. H. Armour. Improvements connected with ovens, furnaces, retorts, or other structures, used in the making of coke or charcoal, or for distilling or roasting carbonaceous matter, or otherwise subjecting carbonaceous matter to the action of heat. July 1.

11,253. S. Alford. An improved method of combustion, applicable to coal, coke, and other inflammable material. July 2.

11,347. J. Hodgson and W. Myland. Improvements in gas lighting. July 3.

11,416. J. Bromilow. Improvements in gas producers. July 4.

11,740. J. H. R. Dinsmore. Improvements in the manufacture of gas for illuminating and heating purposes, and in or connected with apparatus therefor. July 10.

11,764. A. G. Jones. Improvements in the manufacture of artificial fuel, utilising sewage therein. July 10.

11,781. J. H. Hilton. Improvements in apparatus for carburetted gases. July 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

10,329. J. Love. Apparatus for manufacture of illuminating gas. July 1.

11,239. W. H. Buckland and G. Myers. Composition and manufacture of fuel from coal dust, &c. July 1.

11,514. W. Lacey. Manufacture of artificial fuel. July 15.

12,016. W. Foulis. Apparatus for stirring and drawing the charge of gas retorts. July 1.

12,580. C. W. Bartholomew and J. Oxley. Apparatus for drawing coke from coke ovens. July 1.

13,398. W. H. Nevill. Treatment of tar and pitch. July 8.

13,477. M. Fromont. Production of coke and apparatus therefor. July 1.

17,745. T. Cooke. Method of setting clay retorts for the manufacture of coal gas. June 21.

1891.

8068. T. Keetman and W. Bach. Scoop for discharging gas retorts. June 21.

8547. W. H. Beek.—From G. Moreau. Production and drying of compressed air, and usefully applying same. June 21.

9796. H. H. Lake.—From The Standard Coal and Fuel Co. Compound for treating fuel. July 15.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

COMPLETE SPECIFICATION ACCEPTED.

1890.

13,398. W. H. Nevill. See Class II.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

10,619. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. The manufacture and production of new basic dyestuffs. June 22.

10,861. H. H. Lake.—From K. Oehler, Germany. Improvements in the manufacture of colouring matters. June 25.

11,017. J. Dawson and R. Hirsch. The production of artificial indigo. June 29.

11,031. R. Holliday and Sons, R. Holliday, and L. G. Paul. Improvements in the preparation of green colouring matters for dyeing animal fibres. June 29.

11,046. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. The manufacture and production of alpha-naphthoquinone dichlorimide, and of basic dyestuffs therefrom. June 29.

11,049. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brüning, Germany. Manufacture of meta-amidobenzaldehyde, and of salts thereof. June 29.

11,218. H. H. Lake.—From K. Oehler, Germany. Improvements in the manufacture of colouring matter. Complete Specification. July 1.

11,275. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. The manufacture and production of new dyes of the rosaniline series and of new materials therefor. July 2.

11,298. E. Schweich and E. Bueher. New or improved colouring matter or dye, and methods of extracting and utilising the same. July 3.

11,328. O. Imray.—From The Faröwerke vormals Meister, Lucius, and Brüning, Germany. Manufacture of yellow azo-colouring matters striking on mordants, and absolutely fast against the action of felling, soap, and light. July 3.

11,395. R. Holliday and Sons, Limited, and A. G. Brookes.—From T. Holliday, United States. Improvements in the manufacture of azo colours. July 4.

11,472. W. B. Espeut. Improvements in the manufacture of extracts from logwood and other dye woods, also in preparing dyewoods for use in dyeing. July 6.

11,629. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik, Germany. Improvements in the manufacture of basic naphthalene colouring matters and of sulpho-acids therefor. July 8.

11,663. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture of colouring matters for dyeing and printing, derived from benzidine and its analogues. July 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

9825. A. J. Boulton.—From G. Boulet, fils, Donard, and Contamine. See Class XII.

9923. O. Imray.—From C. F. Boehringer, Söhne. Manufacture of pyrazolones. July 1.

12,550. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik. Production of new diphenyl derivatives and a new base for preparation of dyestuffs. June 21.

12,715. B. Willcox.—From the Farbenfabriken vormals F. Bayer and Co. Production of new derivatives of alizarine and its analogues. July 8.

13,010. W. Majert. Manufacture of colouring matters. July 8.

13,235. C. Willcox.—From The Farbenfabriken vormals F. Bayer and Co. Production of azo dyes. July 1.

13,443. B. Willcox.—From The Farbenfabriken vormals F. Bayer and Co. Production of new sulpho-acids of dioxy-naphthalene or amidonaphthol, and of azo colouring matters therefrom. July 1.

13,565. H. H. Lake.—From A. Leonhardt and Co. Manufacture of colouring matters. July 1.

13,710. J. Dawson and R. Hirsch. Production of substituted benzidines (diamidotriphenyls) and colours therefrom. July 8.

14,620. J. Y. Johnson.—From The Badische Anilin and Soda Fabrik. Production of new substantive dyestuffs. July 15.

15,120. O. Imray.—From The Society of Chemical Industry, Basle. Manufacture of black colouring matters. July 8.

1891.

7803. A. Lembach, U. Schleicher, and C. F. Wolf. Manufacture of ortho-oxyquinoline and oxyquinoline derivatives. July 15.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

10,131. C. Masse. Improvements in and relating to chemically retting all kinds of textile substances. June 15.

10,134. G. L. P. Eyre and T. J. Hopkins. Improvements in apparatus for treating and scouring or cleansing wool and other materials, for removing therefrom greasy or other matters, and for analogous cleansing and separating operations. June 15.

10,543. W. R. Comings. Impregnating paper and other fibrous materials. June 20.

10,556. A. M. Clark.—From La Société La Ramen, France. An improved process of ungumming and decorticating textile materials. June 20.

10,644. R. Ingham. An improved compound or mixture for use in sizing yarn and fabrics. June 23.

11,394. A. Mitscherlich. New process of manufacturing from wood fibres capable of being spun, and by-products of the same, and apparatus therefor. July 4.

11,717. A. Frayssé. Improvements in the treatment of samples of crude wool for estimating purposes. Complete Specification. July 9.

11,724. J. I. Bayce. Sizing composition for cotton yarn. Complete Specification. July 10.

11,841. F. Lehner. Improvements in the manufacture of artificial and mixed silk threads, and in apparatus therefor. July 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

9714. J. Miller and J. Miller, jun. Method and apparatus for rendering textiles waterproof by one treatment. June 24.

VI.—DYING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

10,473. E. B. Trueman. An improved solution for use in dyeing black silk lace. June 16.

10,438. E. B. Trueman. An improved solution for use in the dyeing of silk fabrics, yarns, and threads. June 19.

10,678. E. Sutcliffe and G. E. Sutcliffe. Improvements in the dyeing and treatment of cotton and other textile materials. June 23.

11,327. O. Huray.—From The Farbwerke vormals Meister, Lucius, and Brünning, Germany. Process of dyeing silk a solid black by means of alizarine, flavopurpurine, anthrapurpurine, and mixtures of these bodies. July 3.

11,692. J. Bertrand-Leplat. Improvements in apparatus for dyeing or bleaching textile materials. July 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

11,372. A. Mitscherlich. Sizing paper. July 1.

12,907. E. Sykes, D. Sykes, E. Heppenstall, T. Greenwood, and J. W. Whiteley. Apparatus for scouring, dyeing, and drying hanks of yarn, &c. July 8.

11,372. J. Robertshaw. Dyeing, sizing, and washing machines. July 15.

11,829. F. Walton. Bleaching ground cork. July 15.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

10,158. L. Lohmann. Improvements in the production of carbonic acid from bicarbonates of soda. Complete Specification. June 15.

10,168. J. H. Parkinson. See Class IV.

10,202. H. H. Lake.—From The Kayser Patent Co., United States. Improvements in the manufacture of caustic alkali, carbonates of the alkaline metals and muriatic acid, and of bricks, cakes, or blocks for use therein, and apparatus therefor. Complete Specification. June 16.

10,475. C. Braconier. Improvements relating to the conversion of crude phosphates and phosphated chalk into pure phosphates and carbonate of lime, and to the recovery of the substances used in such conversion. June 19.

10,476. Comte T. Brochocki. Improvements in the manufacture of compounds of barium and of peroxide of hydrogen. June 19.

10,617. W. Wolters. Improvements relating to the production of chlorine and hydrochloric acid. June 22.

10,626. A. C. Southwell. Improvements in the treatment of gases and vapours of metallic oxides and sulphides for the purpose of effecting their deoxidation, and in apparatus therefor. June 22.

10,629. E. Edwards.—From O. Guttman and L. Rohrmann, Germany. Improvements in apparatus for the condensation of nitric acid. June 28.

10,630. A. Dupré.—From F. Dupré, Germany. Improvements in the manufacture of potassium carbonate. June 22.

11,099. G. D. Davis. Improvements in the manufacture of lactic acid. June 30.

11,311. T. Goodall.—From S. Peacock and H. A. Galt, United States. Improvements in obtaining chromates and dichromates of potash and soda. July 3.

11,469. T. H. Bell.—From T. Schloesing, France. Improvements in the manufacture of anhydrous chloride of magnesium, and the apparatus used therein. July 6.

11,470. T. H. Bell.—From T. Schloesing, France. Improvements in the manufacture of chlorine, and in the apparatus used therein. July 6.

11,484. L. L. Labois. Improvements relating to the refining of sulphur and the distillation of sulphur and other ores, and to apparatus therefor. July 6.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

4532. E. G. Lawrence.—From S. Pick. Apparatus for evaporating liquors containing salts, and for separating such salts when rendered insoluble by evaporation of the liquors. July 1.

4695. E. G. Lawrence.—From S. Pick. Apparatus for drying salt. July 1.

9,504. T. J. Hutchinson. Obtaining useful products from bleaching-power dregs and lime mud from paper works. July 8.

13,863. B. E. R. Newlands. Treating phosphoric acid to facilitate its storage and transport. July 8.

18,835. J. Simpson. Manufacture of caustic soda, and recovery of reagents employed for repeated use. June 24.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

10,208. J. P. Adams. A method of and apparatus for making balls or other articles from molten glass, or other molten or plastic material. June 16.

10,218. O. Böklen. Improvements in the manufacture of slabs or tiles. Complete Specification. June 16.

10,454. J. Armstrong. Improvements in the manufacture of tanks or boxes and other articles of glass, and in mechanism or appliances to be used in the said manufacture. June 19.

10,661. W. W. Pilkington. Improvements in and connected with kilns for annealing plate glass. June 23.

10,730. H. B. Baker. A process for sealing metallic wires, other than platinum, through glass. June 24.

10,817. I. Pennell and J. T. Harris. Improved apparatus or appliance for use in supporting ceramic ware in enamel kilns whilst being fired. June 25.

11,039. P. Sievert. Improvements in the process of producing glass articles with metal enclosures. June 29.

11,070. D. Rylands. Improvements in the process of glass manufacture. June 30.

11,165. C. Armstrong. Improvements relating to salt glazing of sanitary ware and the like. July 1.

11,205. H. J. Chappell. Improvements in machines for pressing and moulding plastic materials. July 1.

11,386. J. Slack. Apparatus for and method of producing sharp outline and relief in ceramic and other plastic substances. July 4.

11,401. W. B. Fitch. Improvements in the manufacture of glass bottles and similar articles. July 4.

11,509. J. Bilton. Decorating pottery. July 7.

11,556. C. F. Parsons. Improved manufacture of crucibles and similar vessels of plumbago, clay, earthenware, or other plastic material, and apparatus for this purpose. July 7.

11,607. T. M. Rymers-Jones. An improvement in the manufacture of refractory and non-conducting bricks, blocks, tiles, slabs, and pipes. July 8.

11,617. T. Severn. Improvements in kilns for heating or burning pottery and the like. July 8.

11,637. B. A. Spaul. Improvements in the manufacture of glass bottles and the like, and in apparatus therefor. July 8.

11,638. C. C. Bruff and T. J. Bott. The utilisation of worn out, defaced, and broken plaster of Paris moulds used in the manufacture of china and other fictile ware. July 8.

11,752. C. C. Bruff and T. J. Bott. Improvements in or connected with plaster of Paris moulds for use in the manufacture of china, earthenware, and the like. July 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

13,155. L. H. Jahn. Firing pottery. June 21.

13,251. J. Hamblet. Manufacture of ornamental tiles, and apparatus therefor. June 24.

1891.

7885. C. Blount, V. Ward, and A. Fisher. Translucent cloisonné enamel. July 8.

9220. H. Godwin and W. Hewitt. Fender, hearth, wall and other tiles. July 8.

9412. W. James. Ornamenting glass. July 15.

9745. L. Lederer. Producing coloured designs on mirrors. July 15.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

10,137. H. H. Lake.—From H. B. Seely, United States. Improvements in the construction of floors. June 15.

10,168. J. H. Parkinson. Improvements in obtaining lime (CaO) from limestone (CaCO₃), and applicable also in the making of cement, whereby the recovery of the carbon dioxide evolved can be effected. June 16.

10,672. C. E. W. Young. Improvements in and connected with asphalt paving. June 23.

10,722. W. T. Ramsden. Improvements in seasoning timber. June 23.

10,767. J. Dent. Improvements in or relating to tiles for use in building or constructing concrete walls. June 24.

11,209. H. Aitken. Improvements in the treatment of stone, brickwork, plaster, or stucco, and the like, for preventing deterioration thereof. July 1.

11,259. E. E. A. Sorel. Improvements in materials for the manufacture of bricks and other articles, the building of fortifications, and the protection of vessels. Complete Specification. July 2.

11,612. H. Heartfield. An improved water and fire-proof fibrous material suitable for the manufacture of plain or decorated wall, ceiling, or floor linings, electrical and other conduits, bases, and coverings, and numerous other purposes for which wood, paper, plaster, and cement are now used. July 8.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

10,427. W. Darling. Calcining carbonates for cements, &c. June 24.

13,105. A. McLean. Decorative artificial stone. July 8.

1891.

2911. F. G. Edwards. Combination of iron and concrete, &c., for building purposes. July 1.

8017. O. Imray. — From F. Zernikow. Apparatus employed in the manufacture of artificial sand-stone. July 1.

8875. J. J. Mead. Lime grinding mill. July 1.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

10,114. P. H. Bertrand. An improved method of forming magnetic oxide (Fe₃O₄) upon the surface of wrought or cast iron. June 15.

10,141. G. Bamberg. Improvements in extracting gold from ore. June 19.

10,587. Davies Bros. and Co., Limited, and M. Bayliss. Improvements in the method of and apparatus employed in coating metal sheets with spelter or other metal or metallic alloy. June 22.

10,761. C. W. Bildt, G. Ashworth, and E. Ashworth. Improvements in linings for Bessemer converters. June 24.

10,872. L. Cameron. Improvements in the manufacture of puddled iron. June 26.

10,984. F. H. Mason. A process for the extraction of tin from tin slags or tin refuse by foundlers' ashes, copper salts, carbonaceous matter, fluorspar, and other suitable fluxes. June 27.

10,985. F. H. Mason. A process for the extraction of tin from tin slags and tin refuse by lead or its salts, carbonaceous matter, fluorspar, and other suitable fluxes. June 27.

11,033. J. J. Meldrum, T. F. Meldrum, and E. Harris. Improvements in or connected with puddling and like furnaces. June 29.

11,083. J. Bowing. Improvements in the method of treating blue billy or purple iron ore, iron, sand, and similar substances, for the purpose of preparing them for the reducing furnace. Complete Specification. June 30.

11,095. J. S. Taylor and S. W. Challen. Improvements in the process or method of manufacturing metal tubes. June 30.

11,177. E. Polte. Improvements in or relating to the spinning of metal. July 1.

11,190. F. W. Harbord and W. Hutchinson, jun. The utilisation of tin plate scrap. July 1.

11,208. J. Turton. A process for extraction of metals from ores and minerals containing them. July 1.

11,247. L. Reuleaux. Improvements in the construction and working of smelting and melting furnaces. July 2.

11,279. C. James. An improved method or process for the production of zinc or spelter from ores or compounds containing the same. Complete Specification. July 2.

11,337. C. James. An improved method or process for the collection of refined copper. July 3.

11,342. H. Parkes and J. C. Montgomerie. Improvements in the extraction of gold and silver from ores or compounds containing the same. July 3.

11,373. The Manchester Oxygen (Bri's Patent) Co., Lim., and W. M. Jackson. Improvements in the application of oxygen and other gases to the welding and autogenous soldering of metals. July 4.

11,502. J. L. B. Higgin. Making hardware of a porous nature on the outside, and with a liquid resisting glaze on the inside, to be entitled "Pour us" or otherwise. July 7.

11,563. C. James. An improved method or process for the production of zinc or spelter from ores or compounds containing the same. Complete Specification. July 7.

11,616. H. E. Fry, A. Hermann, O. L. A. P. Dresel, R. H. Everett, and H. A. Penrose. Improvements in or relating to the treatment of silver ores containing zinc, and gold ores containing zinc. July 8.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

11,323. G. Hilgenstock and J. Massenez. Separating sulphur from sulphurous pig iron. July 1.

12,432. T. Parker and A. E. Robinson. Production of zinc from oxidised ores of zinc. July 8.

12,912. G. Rodger. Apparatus for making steel. June 24.

13,356. H. G. Castrer. Manufacture of sodium and potassium. July 1.

13,856. F. Burger and R. Mannheim. Product or compound for preventing formation of pores in molten metals, and manufacture of same. July 8.

14,063. H. H. Lake. From C. F. Claus. Annealing wire, sheet metal, &c. July 15.

16,107. J. O. Day. Alloys and compositions for covering metallic and other surfaces, to prevent corrosion and fouling when submerged. July 15.

1891.

673. O. B. Peck. Apparatus for centrifugally treating particles of metallic or mineral bearing substances of different degrees of specific gravity. July 15.

1208. H. H. Lake. From J. H. Bevington. Shaping or forming and welding metal tubes, &c. July 15.

6080. J. D. Wilson. Cupolas. July 15.

8111. R. J. R. Mills. From W. L. Brockway. Treating waste turned steel or iron. June 24.

9143. A. Torkington. From N. K. Morris. Apparatus for use in the manufacture of lead fibre. July 8.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

10,347. D. Fitzpatrick. Improved electric battery. June 18.

10,374. F. R. E. Branstom. Improvements in the production of light and the generation of heat and electricity. June 18.

10,977. A. de Meritens. Improvements in galvanic batteries. Filed June 27. Date applied for 28th November 1890, being date of application in France.

10,978. Siemens Bros. and Co., Lim. From Siemens and Halske, Germany. Improvements in insoluble porous anodes for electrolytical processes. June 27.

11,060. P. Giraud. Improvements in thermo-electric batteries. June 30.

11,108. T. Cond. Improvements in or connected with electric primary batteries. June 30.

11,134. C. A. Faure. Improvements in apparatus for the electrolysis of aluminium. June 30.

11,225. F. J. Rehman. The improvement of production of electricity by means of a dry cell battery. July 2.

11,278. E. Hancock and A. J. Marquand. Improvements in the production of elements for electric or secondary batteries. July 2.

11,560. G. G. M. Hardingham. From J. R. Hard and H. Connett, United States. Improvements in and relating to galvanic batteries. July 7.

11,620. E. E. Lever. Improvements in apparatus for preparing bleaching solution and bleaching powder by electrolysis. July 8.

11,712. H. C. Bull. Improvements in or connected with electric batteries. July 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

13,735. C. Hoepfner. Apparatus for use in electro-metallurgical operations. July 8.

1891.

5638. W. A. Crowds. Electric batteries. July 15.

8573. J. Y. Johnson. From J. Weir. Production of hydrocarbon products for use for insulating purposes. June 24.

8648. E. Bazin. Use of compressed air for producing electric light and cold. July 1.

9627. C. D. Abel. From R. J. Galeher and J. Pintoeh. Thermo-electric batteries. July 15.

9928. G. A. Schoth. Galvanic batteries. July 15.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

10,432. C. Fink. Improvements in and relating to lubricants for machinery. June 15.

10,516. R. J. Jordan. An improved compound for cleansing purposes. June 20.

10,837. O. C. Hagemann and T. C. Palmer. See Class XIII.

11,477. J. Y. Johnson. From P. Ribard, France. Improvements in filtering or expressing oils or liquids from seed or other materials, and in the construction of the apparatus employed therein. July 6.

11,799. N. M. Henderson. Improvements in treating or purifying paraffin wax, and in apparatus therefor. July 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

9825. A. J. Boulton. From G. Boulet, fils, Donard, and Contamine. Apparatus for extraction of fats or oils, sulphur, and other material, and for manufacturing extracts for dyes. July 1.

11,360. J. Baptista. Facilitating the use of mineral or other non-saponifiable oils in the manufacture of soaps. July 1.

17,275. C. R. Hingworth. Soaps for diseases of the skin.

1891.

2244. W. S. Somers. Producing and refining spirits from oils and apparatus therefor. July 8.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

10,524. A. E. Rath. An improvement in the manufacture of india-rubber. Complete Specification. June 20.

10,528. A. F. B. Gomes. Improved process of de-vulcanising vulcanised india rubber, gutta-percha, and similar gums, and reclaiming the rubber therefrom for remanufacture, without the addition of pure rubber. Complete Specification. June 20.

10,822. C. N. Jackson. A compound preparation to be used as a substitute for gutta-percha and similar products for insulating and water-proofing purposes. June 25.

10,837. O. C. Hagemann and T. C. Palmer. Improvements in the manufacture or treatment of varnish, oils, and the like, and in apparatus therefor. June 25.

11,207. C. Henry. Manufacture of phosphorescent sulphide of zinc, and the application thereof to vehicles or substances used for washing, dyeing, painting, and printing. July 1.

11,613. F. G. Treharne and W. H. Eastwood. An improved process for the manufacture of white lead. July 8.

11,627. C. H. Bigland. Improvements in anti-fouling or other compositions or paints. July 8.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

12,414. E. V. Gardner. Manufacture of white lead and apparatus therefor. June 24.

1891.

8161. H. H. Lake.—From E. W. Dahl. Manufacture of white lead. July 15.

8347. C. Wittkowsky. Composition of matter consisting in casein cement. July 8.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

10,596. B. Cannon and W. J. Cannon. An improvement in or relating to the manufacture or treatment of size, the same being also applicable to the manufacture or treatment of glue and of gelatin. June 22.

10,871. B. Whiteley. Improvements in the manufacture of mats, rugs, and similar articles from the skins of animals, such as sheep and the like. June 26.

XV.—AGRICULTURE AND MANURES.

APPLICATION.

10,265. W. Newton. The production of a strongly basic phosphate of lime for use as a manure. June 17.

COMPLETE SPECIFICATION ACCEPTED.

1891.

9348. C. Glaser. Treating phosphorites or other phosphatic materials. July 8.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

10,313. W. B. Giles and C. E. Eastick. Improvements for the manufacture of sugars, glucoses, and other saccharine solutions. June 17.

10,414. W. Bergius. See Class XVII.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

10,331. A. Lefranc, L. Lefranc, and A. Vivien. Manufacture of sugar. July 8.

1891.

9115. J. C. Firth. Cleaning kauri gum. July 8.

9665. E. Ruescher. Separating impure sugar masses at one operation into crystallised sugar and molasses, avoiding all other products. July 15.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

10,135. P. M. Justice.—From A. W. Billings, United States. An improved method of and means for manufacturing beer and ale. June 15.

10,414. W. Bergius.—From C. Liesenberg, Germany. An improved composition for and process of clarifying liquids. June 19.

10,659. H. Wilson. An improvement in cooling or refrigerating appliances for cooling brewers' wort and other liquids. June 23.

11,123. M. A. Adams and C. S. Meacham. New or improved means for the preservation of hops. June 30.

11,153. A. Saviegar and T. J. Scrutton. An improved fermenting vat. July 1.

11,183. F. Bollmann. Improvements in malting. Complete Specification. July 1.

11,237. T. White and J. Lee. Improvements in apparatus employed in the brewing of beer. July 2.

11,549. J. J. W. Peters. Improved process of manufacturing alcohol. July 7.

11,687. J. L. B. Higgin. Producing an "artificial condition" in ales, wines, and spirits by a process of heating them in winter, and cooling in summer. July 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

12,834. F. Sauer. Malt wine. June 24.

13,862. B. E. R. Newlands. Treatment of grain and malt, and production therefrom of a new product for use in brewing and distilling or as a food. July 8.

15,790. E. R. Budden. Method and apparatus for maturing wine and like beverages. July 8.

17,329. J. Rose. Brewing oatmeal stout and porter. June 21.

18,099. T. P. Hinde. Improved boiling coppers, and an arrangement of brewing plant for use therewith. July 1.

1891.

2241. W. S. Somers. See Class XII.

8512. C. Funk. Fermenting mash, dough, wort, &c. June 24.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

10,279. R. Silcock. Improvements in or appertaining to the manufacture of food for animals. June 17.

10,415. A. Collingridge.—From V. Cornet and A. Jones, France. Improvements in the treatment of common salt intended to be used for curing food, such as meat, game, fish, and poultry. June 19.

11,045. E. Leconte. Improvements in the preparation of leaven for use in the manufacture of bread, pastry, and biscuits. June 29.

11,142. F. W. Crowther. A new or improved digestive condiment for human use. June 30.

11,557. O. Imray.—From Bonne Paraf-Javal nee Vanderheym, and J. A. J. Paraf-Javal, France. Application of compounds of strontium to alimentary hygienic and medicinal purposes. July 7.

B.—Sanitary Chemistry.

10,181. T. Thorpe and J. Birtwistle. Improvements in continuous precipitation apparatus for the treatment of sewage and other liquids having solid matters suspended therein. June 16.

10,563. A. Hossack and H. C. Bull. Improvements in the treatment of sewage, and in obtaining certain useful products thereby. June 20.

10,929. W. E. Adeney. Improvements in the treatment of sewage sludge. June 26.

11,557. O. Imray. — From Bonne Parat-Javal nee Vanderheym, and J. A. J. Parat-Javal, France. See Class XVIII., J.

11,716. E. Christfield. Improvements relating to the purification of sewage and the consumption of town refuse, and to the utilisation of sewage and town refuse for obtaining motive power, and to apparatus therefor. Complete Specification. July 9.

11,761. A. O. Jones. See Class II.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

10,313. F. Sessler. Treatment of refuse material for obtaining valuable products therefrom. July 8.

1891.

2729. J. E. Kierby. Apparatus for automatically regulating the supply of precipitating materials to sewage, and for analogous purposes. June 24.

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATION.

10,543. W. R. Comings. See Class V.

COMPLETE SPECIFICATION ACCEPTED.

1890.

7816. J. A. London. Treatment of peat fibre for the manufacture of brown paper, millboards, &c. June 17.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

10,980. O. Imray. — From C. F. Boehringer and Soehne, Germany. Manufacture of dehydromethylphenylhydrazine. June 27.

11,833. B. Willeox. — From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture and production of pharmaceutical compounds. July 11.

11,844. J. F. von Mering. An improved anæsthetic and hypnotic. July 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

12,729. H. Cumber. A compound of sugar with the salts of phosphorus for dietetic purposes. July 1.

1891.

2241. W. S. Somers. See Class XII.

8541. P. A. Newton. — From the American Enlleurage Co. Manufacture of medical extracts. June 24.

XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

APPLICATIONS.

10,101. J. Joly. Improved methods of obtaining solar altitudes by the aid of instantaneous photography. June 15.

11,265. E. Thomas. Improvements in the methods of employing materials that are sensitive to radiant energy such as light. July 2.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

13,836. J. J. Acworth. Manufacture of photographic films, and apparatus therefor. July 8.

1891.

8557. A. J. Boulton. — From J. North. Improvements in photography. July 8.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

10,593. E. Davies. Improvements connected with explosive and non-explosive projectiles, and in an explosive compound to be used with the explosive projectiles. June 22.

10,717. J. Selwig and B. Lange. Improved manner and apparatus for nitrating cotton, cellulose, straw, &c. June 24.

11,273. G. W. Thomas. Improvements in matches, fuses, and the like. July 2.

11,326. W. E. Gedge. — From the California Explosive Company, United States. An improved method of purification of nitro-glycerin, and an explosive compound prepared therewith. Complete Specification. July 3.

11,383. C. H. Curtis and G. André. Improvements in the manufacture of gunpowder. Complete Specification. July 4.

11,393. C. H. Curtis and G. G. André. Improvements in the manufacture of gunpowder. July 4.

11,713. M. Reuland. Manufacture of explosives. July 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

15,001. W. Norres. Safety fuse for exploding petards. June 24.

1891.

4381. F. A. Ventris. Improvements in matches. July 8.

XXIII.—ANALYTICAL CHEMISTRY.

APPLICATION.

10,492. J. Laidlaw. Improvements in centrifugal apparatus for testing samples of milk. Complete Specification. June 20.

THE JOURNAL

OF THE

Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 8.—VOL. X.]

AUGUST 31, 1891.

[Non-Members 30/- per annum; Members 21/- per Set of extra or back numbers; Single Copies (Members only) 2/6.

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roseoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond, F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.

COUNCIL FOR YEAR ENDING JULY, 1892.

President: Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.

Vice-Presidents:

Sir Lowthian Bell, Bart., F.R.S.	Ludwig Mond, F.R.S.
Wm. Crowder	Dr. Hugo Müller, F.R.S.
James Duncan	B. E. R. Newlands.
Dr. John Evans, F.R.S.	J. C. Stevenson, M.P.
David Howard	A. Norman Tate.
S. H. Johnson	Sir John Turney.

Ordinary Members of Council:

A. H. Allen.	E. K. Muspratt.
Arthur Boake.	T. L. Patterson.
Jno. Calderwood.	Boverton Redwood.
Dr. Charles Dreyfus.	Jno. Spiller.
H. Grimsshaw.	T. W. Stuart.
Prof. R. Meldola, F.R.S.	William Thorp, B.Sc.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Dr. F. Hurter.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

A. H. Allen.	Prof. A. K. Huntington.
L. Archbutt.	F. Hurter, Ph.D.
G. H. Bailey, D.Sc., Ph.D.	Wm. Kellner, Ph.D.
Joseph Bernays, M.I.C.E.	Ludwig Mond, F.R.S.
H. Brunner.	T. W. B. Mumford.
E. Rider Cook.	B. E. R. Newlands.
W. Y. Dent.	John Pattinson.
Chas. Dreyfus, Ph.D.	W. H. Perkin, Ph.D., F.R.S.
John Heron.	Boverton Redwood.
D. B. Hewitt, M.D.	John Spiller.
David Howard.	A. Norman Tate.
Prof. J. J. Hummel.	Wm. Thorp.
	Thomas Tyrer.

Editor:

Watson Smith, University College, London, W.C.

NOTICES.

Prints of the group photographed at Trinity College, Dublin, may be had on application to W. Lawrence, Photographer, 5—7, Upper Sackville Street, Dublin, price 5s. each.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. Fyfe and Spottiswoode, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January and May 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

The Society's Office will be closed from September 1st to September 15th.

CHANGES OF ADDRESS

Allan, Jno., 10 Crane Court; 3, Ludgate Circus Buildings, London, E.C.

Austen, Prof. P. T., 10 New Brunswick; 569, Vernon Avenue, Long Island City, N.Y., U.S.A.

Banister, H. C., 10 Dale Street; G. 11, Exchange Buildings, Liverpool.

Bickett, G. H., 10 Warrington; c/o W. Maenab, 14, Great Smith Street, Westminster, S.W.

Bothamley, C. H., 10 Leeds; Taunton, Somerset.

Bouquet, Dr. R., 10 Crayford; La Boissière, Geneva, Switzerland.

Brunner, J. L., M.P., 10 Northwich; Druid's Cross, Wavertree, Liverpool.

REPORT TO THE UNITED STATES INTERNAL REVENUE DEPARTMENT AS TO STANDARDS AND METHODS FOR THE POLARIMETRIC ESTIMATION OF SUGARS.

By C. A. CRAMPTON, Chemist of U.S. Internal Revenue; H. W. WILEY, Chief Chemist of U.S. Department of Agriculture; and O. H. TITTMANN, Assistant in Charge of Weights and Measures U.S. Coast and Geodetic Survey.

SECTION I, paragraph 231, of the Act entitled "An Act to reduce revenue and equalise duties on imports and for other purposes," approved October 1, 1890, provides:

"231. That on and after July first, eighteen hundred and ninety-one, and until July first, nineteen hundred and five, there shall be paid, from any moneys in the treasury not otherwise appropriated, under the provisions of section three thousand six hundred and eighty-nine of the Revised Statutes, to the producer of sugar testing not less than ninety degrees by the polariscope, from beets, sorghum, or sugar-cane grown within the United States, or from maple sap produced within the United States, a bounty of two cents per pound; and upon such sugar testing less than ninety degrees by the polariscope, and not less than eighty degrees, a bounty of one and three-fourth cents per pound, under such rules and regulations as the Commissioner of Internal Revenue, with the approval of the Secretary of the Treasury, shall prescribe."

It is the opinion of this Commission that the expression "testing * * * degrees by the polariscope" used with reference to sugar in the Act, is to be considered as meaning the percentage of pure sucrose the sugar contains, as ascertained by polarimetric estimation.

It is evident that a high degree of accuracy is necessary in the examination of sugars by the Bureau of Internal Revenue, under the provisions of this Act, inasmuch as the difference of one-tenth of one per cent. in the amount of sucrose contained in a sugar, may, if it is on the border line of 80°, decide whether the producer is entitled to a bounty of 1½ cents per pound (an amount nearly equivalent to the market value of such sugar), or to no bounty whatever. It is desirable, therefore, that the highest possible degree of accuracy should be secured in the work, for while many sugars will doubtless vary far enough from either of the two standard percentages fixed upon in the Act, viz., 80° and 90°, to admit of a wide margin of error without material consequences, yet a considerable proportion will approximate to them so closely, that a difference of a few tenths of a degree in the polarisation will change the classification of the sugar.

A very high degree of accuracy may be obtained in the optical estimation of sugars, if the proper conditions are observed. Such conditions are (1) accurately graded and adjusted instruments, weights, flasks, tubes, &c.; (2) skilled and practised observers; (3) a proper arrangement of the laboratories in which the work is performed; and (4) a close adherence to the most approved methods of manipulation.

On the other hand, if due observance is not paid to these conditions, the sources of error are numerous, and inaccurate results inevitable.

We will endeavour to point out in this report the best means of meeting the proper conditions for obtaining the highest degree of accuracy consistent with fairly rapid work. It would be manifestly impossible to observe so great a refinement of accuracy in this work as would be employed in exact scientific research. This would be unnecessary for the end in view, and impossible on account of the amount of time that would be required.

I.—INSTRUMENTS AND APPARATUS.

It is of the greatest importance that the polariscopes and all apparatus used in the work shall be carefully and

accurately adjusted and graduated, and upon a single and uniform system of standardisation. Recent investigations of the polarimetric work done in the Customs branch of the Treasury Department have shown that a very considerable part of the want of agreement in the results obtained at the different ports was due to a lack of uniformity in the standardisation of the instruments and apparatus.

(a.) *The Polariscopes.*—There are many different forms of this instrument used. Some are adapted for use with ordinary white light, and some with monochromatic light, such as sodium ray. They are graduated and adjusted upon various standards, all more or less arbitrary. Some, for example, have their scales based upon the displacement of the polarised ray produced by a quartz plate of a certain thickness; others upon the displacement produced by an arbitrary quantity of pure sucrose, dissolved and made up to a certain volume and polarised in a certain definite length of column. It would be very desirable to have an absolute standard set for polariscopic measurements, to which all instruments could be referred, and in the terms of which all such work could be stated. This Commission has information that an investigation is now in progress under the direction of the German Imperial Government, having for its end and purpose the determination of such data as will serve for the establishment of an absolute standard. When this is accomplished, it can easily be made a matter of international agreement, and all future forms of instruments be based upon it. This Commission would suggest that the attention of the proper authorities should be called to the desirability of official action by this Government with a view to co-operation with other countries for the adoption of international standards for polarimetric work. Until this is done, however, it will be necessary for the Internal Revenue Bureau to adopt, provisionally, one of the best existing forms of polariscope, and by carefully defining the scale of this instrument, establish a basis for its polarimetric work which will be a close approximation to an absolute standard, and upon which it can rely in case of any dispute arising as to the results obtained by the officers of the bureau.

For the instrument to be provisionally adopted by the Internal Revenue Bureau, this Commission would recommend the "half shadow" instrument made by Franz Schmidt and Haensch, Berlin. This instrument is adapted for use with white light illumination, from coal oil or gas lamps. It is convenient and easy to read, requiring no delicate discrimination of colours by the observer, and can be used even by a person who is colour blind. This form of instrument is adjusted to the Ventzke scale, which, for the purposes of this report, is defined to be such that 1° of the scale is the one hundredth part of the rotation produced in the plane of polarisation of white light in a column 200 mm. long, by a standard solution of chemically pure sucrose at 17.5° C. The standard solution of sucrose in distilled water being such as to contain, at 17.5° C. in 100 cc., 26.048 grms. of sucrose.

In this definition the weights and volumes are to be considered as absolute, all weighings being referred to a vacuum.

The definition should properly be supplemented with a statement of the equivalent circular rotation in degrees, minutes, and seconds, that would be produced by the standard solution of sugar used to read 100° on the scale. This constant is now a matter of investigation, and it is thought best not to give any of the hitherto accepted values. When this is established, it is recommended that it be incorporated in a revision of the regulations of the Internal Revenue relative to sugar, in order to make still more definite and exact the official definition of the Ventzke scale.

The instruments should be adjusted by means of control quartz plates, three different plates being used for complete adjustment, one reading approximately 100° on the scale, one 90°, and one 80°.

These control quartz plates should have their exact values ascertained in terms of the Ventzke scale by the office of weights and measures by comparison with the standard quartz plates in possession of that office, in strict accordance with the foregoing definition, and should also

be accompanied by tables giving their values for temperatures from 10 to 35°.

(b.) *Weights*.—The weights used should be of solid brass, and should be standardised by the office of weights and measures.

(c.) *Flask*.—The flasks used should be of such a capacity as to contain at 17.5° C. 100.00 cubic centimetres, when filled in such a manner that the lowest point of the meniscus of the surface of the liquid just touches the graduation mark. The flasks will be standardised to contain this volume in order that the results shall conform to the scale recommended for adoption without numerical reduction of the weighings to vacuo. They should be calibrated by the office of weights and measures.

(d.) *Tubes*.—The tubes used should be of brass or glass, 200 and 100 millimetres in length, and should be measured by the office of weights and measures.

(e.) *Balances*.—The balances used should be sensitive to at least one milligramme.

II.—SKILLED OBSERVERS.

The Commission recommends that the work of polarising sugars be placed in the hands of chemists, or at least of persons who are familiar with the use of the polariscope and have some knowledge of the theory of its construction, and of chemical manipulations. To this end we would suggest that applicants for positions where such work is to be done should be obliged to undergo a competitive examination in order to test their fitness for the work that is to be required of them.

III.—ARRANGEMENT OF LABORATORIES.

The arrangement of the rooms in which polarisations are performed has an important bearing upon the accuracy of the results obtained.

Polariscopic observations are made more readily and accurately if the eye of the observer is screened from diffused light; therefore, a partial darkening of the room, which may be accomplished by means of curtains or hangings, is an advantage. On the other hand, the temperature at which the observation is made has a very considerable influence upon the results obtained, so that the arrangements for darkening the room must not be such as will interfere with its proper ventilation. Otherwise the heat from the lamps used, if confined within a small room, will cause considerable variations in the temperature of the room from time to time.

The proper conditions will best be met, in our opinion, by placing the lamps either in a separate room from that in which the instruments are, and perforating the wall or partition between the two rooms for the light to reach the end of the instruments, or in a ventilated hood with the walls perforated in a like manner. By lining the wall or partition on both sides with asbestos paper, and inserting a plate of plane glass in the aperture through which the light passes, the increase of temperature from the radiation of the lamp will be still further avoided. With the lamps separated from the instruments in this manner, the space in which the instruments are contained is readily darkened without much danger of its temperature being duly raised.

Some light, of course, is necessary for reading the scales, and if artificial light is employed for this purpose, the sources chosen should be such that as little heat as possible will be generated by them. Small incandescent electric lights are best for such purpose. Refinements of this kind can not always be used, of course, but the prime requisite with reference to the avoidance of temperature errors is that all operations—filling the flasks and tubes, reading the solutions, controlling the instrument with standard quartz plates, &c.—should be done at one and the same temperature, and that this temperature be a constant one, that is, not varying greatly at different hours of the day. For example, the room should not be allowed to become cold at night, so that it is at low temperature in the morning when work is begun, and then rapidly

heated up during the day. The polariscope should not be exposed to the direct rays of the sun during part of the day, and should not be near artificial sources of heat, such as steam boilers, furnaces, flues, &c.

The tables upon which the instruments stand should be level.

IV.—METHODS OF MANIPULATION.

The methods of manipulation used in the polarisation of sugar are of prime importance. They consist in weighing out the sugar, dissolving it, clarifying the solution, making it up to standard volume, filtering, filling the observation tube, regulating the illumination, and making the polariscopic reading.

The proper conduct of these processes, in connection with the use of accurately graduated apparatus, is the only surety against the numerous sources of error which may be encountered. Different sugars require different treatment in clarification, and much must necessarily be left to the judgment and experience of the operator.

The following directions are based upon various official procedures such as the one used in the United States Custom houses, the method prescribed by the German Government, &c. They embody also the result of recent research in regard to sources of error in polarimetric estimation of sugar:—

DIRECTIONS FOR THE POLARISATION OF SUGAR.

1.—Description of Instrument and Manner of Using.

The instrument employed is known as the half shadow apparatus of Schmidt and Haensch. It is shown in the following cut.

The tube N contains the illuminating system of lenses and is placed next to the lamp; the polarising prism is at O and the analysing prism at H. The quartz wedge compensating system is contained in the portions of the tube marked F, E, G, and is controlled by the milled head M. The tube J carries a small telescope, through which the field of the instrument is viewed, and just above is the reading tube K, which is provided with a mirror and magnifying lens for reading the scale.

The tube containing the sugar solution is shown in position in the trough between the two ends of the instrument. In using the instrument the lamp is placed at a distance of at least 200 mm. from the end; the observer seats himself at the opposite end in such a manner as to bring his eye in line with the tube J. The telescope is moved in or out until the proper focus is secured so as to give a clearly defined image, when the field of the instrument will appear as a round, luminous disc, divided into two halves by a vertical line passing through the centre, and darker on one half of the disc than on the other. If the observer, still looking through the telescope, will now grasp the milled head M and rotate it, first one way and then the other, he will find that the appearance of the field changes, and at a certain point the dark half becomes light, and the light half dark. By rotating the milled head delicately backwards and forwards over this point he will be able to find the exact position of the quartz wedge operated by it, in which the field is neutral, or of the same intensity of light on both halves.

The three different appearances presented by the field are best shown in the following diagram :—

With the milled head set at the point which gives the appearance of the middle disc as shown above, the eye of the observer is raised to the reading tube K and the position of the scale is noted. It will be seen that the scale proper is attached to the quartz wedge, which is moved by the milled head; and attached to the other quartz wedge is a small scale called a vernier, which is fixed, and which serves for the exact determination of the movable scale with reference to it. On each side of the zero line of the vernier a space corresponding to nine divisions of the movable scale is divided into 10 equal parts. By this device the fractional part of a degree indicated by the position of the zero line is ascertained in tenths; it is only necessary to count from zero, until a line is found which makes a continuous line with one on the movable scale.

With the neutral field as indicated above, the zero of the movable scale should correspond closely with the zero of the vernier unless the zero point is out of adjustment.

If the observer desires to secure an exact adjustment of the zero of the scale, or in any case if the latter deviates more than one-half of a degree, the zero lines are made to coincide by moving the milled head and securing a neutral field at this point by means of the small key which comes with the instrument, and which fits into a nipple on the left-hand side of F, the fixed quartz wedge of the compensating system. This nipple must not be confounded with a similar nipple on the right-hand side of the analysing prism H, which it fits as well, but which must never be touched, as the adjustment of the instrument would be seriously disturbed by moving it. With the key on the proper nipple it is turned one way or the other until the field is neutral. Unless the deviation of the zero be greater than 0.5° , it will not be necessary to use the key, but only to note the amount of the deviation, and for this purpose the observer must not be content with a single setting, but must perform the operation five or six times, and take the mean of these different readings. If one or more of the readings show a deviation of more than 0.3° from the general average, they should be rejected as incorrect. Between each observation the eye should be allowed 10 to 20 seconds of rest.

The "setting" of the zero having been performed as above, the determination of the accurate adjustment of the instrument by means of the "control" quartz plates is proceeded with. Three such plates will be furnished with each polariscope, which have "sugar values" respectively, approximating 80° , 90° , and 100° . These values may vary with the temperature, and tables are furnished with them which give their exact value at different temperatures, from 10° to 35° C.

One of these plates is placed in the instrument, and the field observed; it will be seen that the uniform appearance of the field is changed. The milled head is turned to the right until the exact point of neutrality is re-established, just as described above in setting the zero. The scale is read, the observation repeated, the reading taken again, and so on until five or six readings have been made. The average is taken, readings being rejected which show a divergence of more than 0.3° , and the result corrected for the deviation of the zero point, if any was found, the deviation being added if it was to the left, and subtracted if to the right. If the adjustment of the instrument be correct, the result should be the value of the control plate used, as ascertained from the table, for the temperature of 20° . Each of the three plates is read in the instrument in this way. A variation of 0.3° from the established values may be allowed for errors of observation, temperature, &c., but in the hands of a careful observer a deviation greater than this with one of the three plates after a careful setting of the zero, shows that the instrument is not accurately adjusted.

The complete verification of the accurate adjustment of the polariscope by means of three control plates, as given above, should be employed whenever it is set up for the first time by the officer using it, whenever it has sustained any

serious shock or injury, and whenever it has been transported from one place to another. It should also be done at least once a week while the instrument is in active use.

After the complete verification has been performed as described, further checking of the instrument is done by means of one control plate alone, the one approximating 90° , and the setting of the zero point is dispensed with, the indication of the scale for sugar solutions being corrected by the amount of deviation shown in the reading of the 90° control plate from its established value as ascertained from the table, at the temperature of the room.

For example: A sugar solution polarises 80.5° ; the control plate just before had given a polarisation of 91.4° , the temperature of the room during both observations being 25° C. According to the table the value of the control plate at 25° C. is 91.7° ; the reading is, therefore, 0.3° too low, and 0.3° is added to the reading of the sugar solution, making the corrected result 80.8° . The temperature of the room should be ascertained from a standardised thermometer placed close to the instrument and in such a position as to be subject to the same conditions.

PREPARATION OF THE SUGAR SOLUTION FOR POLARISATION.

If the sample is not entirely uniform it must be thoroughly mixed before weighing out, after all the lumps are broken up, best with a mortar and pestle. Then 26.048 grms. are weighed out on the balance in the tared German silver dish furnished for this purpose. Care must be taken that the operations of mixing and weighing out are not unduly prolonged, otherwise the sample may easily suffer considerable loss of moisture, especially in a warm room. The portion of sugar weighed out is washed by means of a jet from a wash-bottle into a 100 cc. flask, the dish being well rinsed three or four times and the rinsings added to the contents of the flask. The water used must be either distilled water or clear water which has been found to have no optical activity. After the dish has been thoroughly rinsed, enough water is added to bring the contents of the flask to about 80 cc. and it is gently rotated until all the sugar has dissolved. The flask should be held by the neck with the thumb and finger, and the bulb not handled during this operation. Care must be taken that no particle of the sugar or solution is lost. To determine if all the sugar is dissolved, the flask is held above the level of the eye, in which position any undissolved crystals can be easily seen at the bottom. The character of the solution is now observed. If it be colourless or of a very light straw colour, and not opalescent, so that it will give a clear transparent liquid on filtration through paper, the volume is made up directly with water to the 100 cc. mark on the flask. Most sugar solutions, however, will require the addition of a clarifying or decolourising agent in order to render them sufficiently clear and colourless to polarise. In such case, before making up to the mark, a saturated solution of subacetate of lead is added.

The quantity of this agent required will vary according to the quality of the sugar; for sugar which has been grained in the strike pan and washed in the centrifugals, from 3 to 15 drops will be required; for sugar grained in the strike pan but not well washed in the centrifugals, that is, sugar intended for refining purposes, from 15 to 20 drops will be required; for sugar not grained in the strike pan, that is, "waggon" or "string sugar," "second sugar," &c., from 1 to 3 cc. will be required. After adding the solution of subacetate of lead the flask must be gently shaken, so as to mix it with the sugar solution. If the proper amount has been added, the precipitate will usually subside rapidly, but if not, the operator may judge of the completeness of the precipitation by holding the flask above the level of the eye and allowing an additional drop of subacetate of lead to flow down the side of the flask into the solution; if this drop leaves a clear track along the glass through the solution it indicates that the precipitation is complete; if, on the other hand, all traces of the drop is lost on entering the solution, it indicates that an additional small quantity of the subacetate of lead is required. The operator must learn by experience the point where the addition should cease; a

decided excess of subacetate of lead solution should never be used.

The use of subacetate of lead should, in all cases, be followed by the addition of "alumina cream" (aluminum hydrate suspended in water) in about double the volume of the subacetate solution used, for the purpose of completing the clarification, precipitating excess of lead, and facilitating filtration. In many cases of high grade sugars, especially beet sugars, the use of alumina alone will be sufficient for clarification without the previous addition of subacetate of lead.

The solution is now made up to the mark by the addition of distilled water in the following manner. The flask, grasped by the neck between the thumb and finger, is held before the operator in an upright position, so that the mark is at the level of the eye, and distilled water is added drop by drop from a siphon bottle or wash bottle, until the lowest point of the curve or meniscus formed by the surface of the liquid just touches the mark. If bubbles hinder the operation, they may be broken up by adding a single drop of ether, or a spray from an ether atomiser, before making up to the mark. The mouth of the flask is now tightly closed with the thumb, and the contents of the flask are thoroughly mixed by turning and shaking. The entire solution is now poured upon the filter, using for this purpose a funnel large enough to contain all the 100 cc. at once, and a watch glass is placed over the funnel during filtration to prevent a concentration of the solution by evaporation.

The funnel and vessel used to receive the filtrate must be perfectly dry. The first portion of the filtrate, about 20 to 30 cc., should be rejected entirely, as its concentration may be affected by a previous hygroscopic moisture content of the filter paper. It may also be necessary to return subsequent portions to the filter until the liquid passes through perfectly clear.

If a satisfactory clarification has not been obtained, the entire operation must be repeated, since only with solutions that are entirely clear and bright can accurate polarimetric observations be made.

When a sufficient quantity of the clear liquid has passed through the filter, the 200 mm. observation tube is filled with it. The 100 mm. tube should never be used except in the rare cases, when, notwithstanding all the means used to effect the proper decolourisation of the solution, it is still too dark to polarise in the 200 mm. tube. In such cases the shorter tube may be used, and its reading multiplied by two. The zero deviation must then be determined and applied to the product. This will give the reading which would have been obtained if a 200 mm. tube could have been used, and it only remains to apply the correction determined by the use of the control plate as previously described.

Example

Solution reads in 100 mm. tube	47.0
Multiplied by 2	2.0
Product	94.0
Zero reads plus 0.1	0.1
Solution would read in 200 mm. tube	93.7
Reading of control plate	99.4
Sugar value of control plate	96.5
Instrument factor by	0.1
Add 0.1 to	93.7
Correct polarisation of solution	93.8

* Prepared as follows. Shake up powdered commercial alum with water at ordinary temperature until a saturated solution is obtained. Set aside a little of the solution, and to the residue add ammonia, little by little, stirring constantly, until the mixture is alkaline to litmus paper. Then drop in additions of the portion left aside, until the mixture is just acid to litmus paper. By this procedure a cream of aluminum hydroxide is obtained suspended in a solution of ammonium sulphate, the presence of which is not at all detrimental for sugar work when added after subacetate of lead, the ammonium sulphate precipitating whatever excess of lead may be present.

Before filling the tube it must either be thoroughly dried by pushing a plug of filter paper through it, or it must be rinsed several times with the solution itself. The cover glasses must also be clean and dry, and without serious defects or scratches. Unnecessary warming of the tube by the hand during filling should be avoided; it is closed at one end with the screw cap and cover glass, and grasped by the other end with the thumb and finger. The solution is poured into it until its curved surface projects slightly above the opening, the air bubbles allowed time to rise, and the cover glass pushed horizontally over the end of the tube in such a manner that the excess of liquid is carried over the side, leaving the cover glass exactly closing the tube with no air bubbles beneath it, and with no portion of the liquid upon its upper surface. If this result is not attained, the operation must be repeated, the cover glass being rubbed clean and dry, and the solution again brought up over the end by adding a few more drops. The cover glass being in position, the tube is closed by screwing on the cap. The greatest care must be observed in screwing down the caps that they do not press too tightly upon the cover glasses; by such pressure the glasses themselves may become optically active, and cause erroneous readings when placed in the instrument. It should therefore be ascertained that the rubber washers are in position over the cover glasses, and the caps should be screwed on lightly. It must also be remembered that a cover glass, once compressed, may part with its acquired optical activity very slowly, and some time must be allowed to elapse before it is used again.

The polariscopic reading may now be taken, an observation on the 90° control plate having been made immediately before as previously described. Then without altering the position of the instrument relative to the light, or changing the character of the latter in any way, the tube filled with the sugar solution is substituted for the control plate. The telescope is adjusted, if necessary, so as to give a sharply-defined field, which must appear round and clear. (This condition must be fulfilled before the observation is performed, as it is essential to accuracy.) The milled head is turned until the neutral point is found, and the reading is taken exactly as previously described, the operation repeated five or six times, the average taken with the rejection of aberrant readings, the average figure corrected for the deviation shown by the control observation from the sugar value of the control plate at the temperature of observation as given in the table, and the result taken as the polarisation of the sugar. When a series of successive polarisations is made under the same conditions as regards temperature, position of the instrument with relation to the high intensity of the light, &c., the control observation need not be made before each polarisation, one such observation being sufficient for the entire series. The control must be repeated at least once an hour, however, and oftener when the operator has reason to think that any of the factors indicated above have been altered, for any such alteration of conditions may change the zero point of the instrument.

In the polarisation of the quartz plates as also in the polarisation of very white sugars, difficulty may be experienced in obtaining a complete correspondence of both halves of the field. With a little practice this may be overcome and the neutral point found, but when it cannot, the ordinary telescope of the instrument may be replaced by another, which is furnished with the polariscope and which carries a yellow plate. This removes the difficulty and renders it possible, even for one not well accustomed to the instrument, to set it at the exact point of neutrality.

SUMMARISED SOURCES OF ERROR.

The following principal sources of error must be especially guarded against:—

1. Drying out of sample during weighing.
2. Excess of subacetate of lead solution in clarification.
3. Incomplete mixing of solution after making up to mark.
4. Imperfect clarification or filtration.
5. Concentration of solution by evaporation during filtration.

6. Undue compression of the cover glass.
7. Alteration of the temperature of room, position of instrument, or intensity of light while the observation or control observation are being performed.
8. Performances of polarisation with a cloudy, dim, or not completely round or sharply-defined field.

In closing this report the members of this Commission hereby signify their intention to promote uniformity and accuracy by adopting and using the standards and general plan of procedure recommended in this report in the polarimetric determinations over which, in their respective branches of government work, they have control.

PRELIMINARY NOTE ON THE TECHNICAL ANALYSIS OF GAMBIEER.

BY H. R. PROCTER, F.R.C.

Lecturer on Leather Industries, Yorkshire College, Leeds.

AT the instance of the Leeds Leather Trades Association, and of the National Morocco Manufacturers' Association of the United States, I sent a circular a few weeks since to those chemists whom I knew to be interested in the analysis of tanning materials both here and on the Continent, asking their opinion as to the possibility of agreeing on a standard method for the analysis of gambier, in order to avoid the serious discrepancies which arise in consequence of all the present processes being rather relative than absolute. In response, I have received much valuable information. My correspondents are unanimously in favour of the "indirect gravimetric method," in which equal quantities of the infusion of the tanning material are evaporated, in the one case after careful filtration through paper only, and in the other after complete removal of the tanning matter by treatment with purified hide powder; and the tanning matter is calculated from the difference of weight of the dried residues. There is, however, considerable diversity of opinion as to the details both of making the infusion, and of carrying out the absorption of the tannin; and I think it will be advantageous if I summarise as briefly as possible the points still requiring discussion, and the respective advantages of the various modifications, in the hope that some chemists may be induced to make independent investigation where it is required. I purpose myself to examine several points in the leather industries laboratory of the Yorkshire College as soon as time allows; and, if other chemists co-operate, I think we may devise a method which will at any rate answer present commercial requirements, and do away with the uncertainty of analytical reports, which, more than anything else, has discredited chemistry in its application to tanning.

It is desirable that such a method should not be confined to gambier, but should be capable with slight modification of general application to all tanning materials. A point of great importance is that of sampling, which, unfortunately, has only been dealt with by one of my correspondents, Mr. Bertram Hunt. I think it will be convenient, however, to begin by saying a few words about it.

The sampling of cube gambier presents no difficulties, and calls for no special remark, except that as the material darkens in colour, and therefore presumably alters in other ways by exposure to the air, it is best to cut up the cubes as short a time before weighing as possible. With block gambier, on the other hand, the difficulties of sampling are great. The "blocks" consist of oblong masses of about 2 cwt. each, wrapped in matting, and quite pasty inside, though tolerably hard on the surface. The only practicable method seems to be to cut a sufficient number of bales across the middle, and to take slices with a fair proportion of inside and outside, to mix the mass as well as possible, and to put it at once in a tight tin or jar to avoid loss of water. It might be worth trying a tubular sampling tool, such as is used for paraffin scale, but from the adhesive

nature of the material success does not seem very probable unless the plug were forced out with a piston. The following method has been found satisfactory by Mr. Bertram Hunt, but unfortunately it is not generally applicable. "Slices from a number of bales are taken and weighed (at least 1 cwt. from a large lot), and dissolved by agitation in a known quantity, say an equal weight of hot water; and a definite quantity of the mixture weighed off for analysis." Possibly the same method on a smaller scale might be employed to utilise and average large samples in the laboratory, but the thick liquid would require very careful mixture.

With regard to solution it is unnecessary, and possibly undesirable to boil the solution, though Mr. Hunt's experiments on the destruction of gambier tannin by boiling (this Journal, 4, 266) only applied to such strong infusions as have just been described. All the valuable constituents of gambier are soluble in water near the boiling point. These consist of catechutannic acid, which is soluble in water at all temperatures and catechin, which, according to Zwenger, is soluble in three parts of boiling water and in 1,133 parts at 17° C. Catechin is not a tannin, though it is said by Etti to be converted into catechutannic acid by dehydration, which goes on slowly even at ordinary temperatures in vacuo over sulphuric acid, or at 100° C. on the water-bath.

Opinions differ as to its tanning value (Mr. Hunt considers that it plays a great part in gambier tanning), but it is quite clear that a body so easily converted into tannin cannot be disregarded in analysis, as it practically would be by the use of strong solutions and cold filtration. It is certainly taken up by raw hide in the hide-powder filter. In practical tanning it remains suspended in the liquor in the form of fine acicular crystals, which gradually disappear, probably by slow solution and absorption by the hide.

Many tanning materials, even gambier itself, to some extent, contain other matters, generally red or brown amorphous bodies, of the nature of tannins, and probably anhydrides of the more soluble tannic acids, which are freely soluble in hot water, but gradually deposited on cooling, so that similar questions arise in the analysis, and especially so in the case of hemlock and quebracho extracts; and it will be seen that in these cases the more dilute solution, the higher will be the result in soluble tannins. It is not possible, however, in practice to use solutions so dilute as to insure the solution of all matters capable of being absorbed by hide. The whole might be estimated by hot filtration, but the result in the case of many extracts would be to give a very unfair advantage to the low-grade makers, who, by extracting at high temperatures, and under pressure, get an inordinate proportion of such dark-coloured matters, which are to a great extent lost in tanning, from their insolubility in liquors of ordinary strength, and which are very injurious to the colour of the leather. Probably 8–12 per cent. is quite an ordinary proportion of such difficultly soluble matters in a hemlock extract; and, once precipitated, a considerable proportion cannot be re-dissolved by boiling. The method of cooling such infusions is of importance, as well as the temperature and proportion of water: since the separation takes time, and higher results in soluble matter will therefore be obtained by rapid cooling under the tap, than by allowing to stand overnight in the laboratory.

In the Vienna laboratory, solutions leaving about 1.2 grms. of total extract are employed, the extract or gambier being dissolved in hot water, cooled, and filtered. Supposing Zwenger's figures to be approximately correct for the catechin of gambier, which is by no means certain, as they were obtained from that of cutch, which may not be identical, the Vienna method would estimate about 5 per cent. of catechin on the weight of the gambier employed.

Professor von Schroeder, at Tharandt, and Dr. Koch, at Leipzig, use solutions containing 0.2–0.5 gm. per 100 cc., dissolving hot, cooling rapidly with water, and filtering as soon as cool. The first 100 cc. of the filtrate is rejected, to avoid loss by possible absorption of tannin by the paper,* which Professor von Schroeder has shown to

* Dingl. J. 1888, 269, 38–82.

occur with some materials. This method would of course estimate most of the catechin; and a considerably larger amount of difficultly soluble tannins in extracts such as hemlock and quebracho, than the stronger solution.

Mr. Hunt uses 10 grms. per litre, or slightly more than the above, dissolves hot, allows to subside overnight, but does not filter, believing that tannin is absorbed by the paper. Catechin remains to a considerable extent suspended as a fine crystalline precipitate, and is thus partially estimated. The method seems to give pretty constant results, but the use of a partially turbid solution seems indefinite, and will not commend itself to most chemists.

Dr. Maschke, Director of the Laboratory of the German Tanners' Association in Berlin, uses 10 grms. gambier, which he dissolves in a beaker, stirring with a glass rod and decanting and washing the insoluble residue with successive quantities of water. The infusion is made up to 1 litre and filtered through sand under pressure in an apparatus similar to Koch's extractor. The hide-powder filter is used.

The estimation of the catechin and of difficultly soluble tannins would be easily accomplished by filtering at 100° C., cooling rapidly, and after well shaking, measuring and evaporating 50 or 100 cc. of the turbid liquor. Experiments are required to ascertain whether under these conditions tannin is absorbed by paper to a serious extent. If this is so possibly a sand-filter might be substituted. After complete cooling, the liquor might be re-filtered, and the percentage soluble in 100 or 200 volumes of cold water ascertained by evaporating another 50 cc.

Dr. R. Koch recommends a double determination of easily and difficultly soluble tannin by making a concentrated solution, and diluting an aliquot part before filtration. This is a very practicable method, but its results would depend on the concentrations employed, which would have to be a matter of convention. If 1.0—1.2 gm. total extract per 100 cc. were adopted as the higher limit and 0.2—0.3 gm. as the lower, the results would represent those of the Vienna and Thurnandt schools respectively, and this seems to me a method of harmonising the two which is well worth consideration. It does not seem certain that dilution before and after cooling would yield the same results, or in other words, that the once separated phlophen-tannins would redissolve completely on dilution, and whether this is so, should be determined by experiment.

Possibly, as gambier is often used warm in the tannery, the filtration might be taken at 30° instead of 15° C., so as to include a large proportion of the whole of the catechin, but this could only be done under a very definite convention to which buyers as well as sellers had agreed. It is clear that no proportion of cold water could be practically used, which would insure the solution of the whole of the catechin, but it would be desirable to experiment on the influence of changes in this respect.

Another method which suggests itself as practicable, but which I have not yet been able to experiment on, is to dissolve in a determined quantity of water, filter off the amount required for analysis while hot through a tared filter, which would be best supported in a cone of wire gauze, supported if necessary. The filtrate would be cooled and returned to determine the "easily soluble" tannin, while the cone and filter would be placed in the top of a beaker with a little water boiling over a lamp, and thoroughly washed with boiling water so long as anything was dissolved. The filter dried and weighed, would give "fibre and insoluble matter," and the "catechin and tannin (or phlophenes)" soluble at 100° could easily be got by difference. The determination of fibre and actually insoluble matter would throw much light on some reported adulterations. It is possible that the filter might become so choked as to render the washing impracticable, but I have found the use of steam very effective in preventing this with similar materials.

With regard to absorption of the tannin by hide-powder much depends on the strength of the infusion employed. With dilute infusions of say 10 grms. black gambier per litre, the hide-powder filter may be used; but it has little advantage over a short-digestion in a flask, and it is of small importance whether the hide powder is added in successive portions, or all at once, since the infusion is not strong enough to harden the surface. Hunt for instance adds

5 grms. hide-powder to 100 cc. of infusion, digests with frequent shaking for six hours, and finds tannin completely removed. Mr. A. N. Palmer, using a liquor of about 0.4 gm. of total extract per 100 cc., mixes 3 grms. of hide powder with 30 cc. of liquor and percolates in a wide tap burette plugged with cotton-wool, rejecting the liquor. He then adds 70 cc. more liquor and percolates twice for about half an hour, returning the filtrate. The tannin is completely absorbed, and the use of 4 grms. hide-powder makes no difference. On the other hand with strong solutions of, say 20 grms. per litre, with "total extract" 1.0—1.2 grms. per 100 cc., it is necessary either to add the powder in successive quantities, or to use the hide-powder filter in which a great part of the tannin is absorbed by the first portions with which the liquor comes in contact.

The essential objects to be kept in view are:—1st, to completely absorb the tannin; 2nd, to avoid any error arising from the solubility of the hide; and 3rd, to minimise the merely mechanical absorption of indifferent matters. To attain as far as possible all these ends, the quantity of hide-powder must be enough, and not too much; and as all hide-powder yields traces of soluble matter to cold water, a constant quantity should be used, and a suitable correction applied. If these conditions are fulfilled, it is indifferent whether it be by the hide-powder filter, or by mere maceration. It is also a matter of comparative indifference within certain limits whether the infusion is strong or weak, since a strong solution requires a larger quantity of hide-powder, and the dissolved matter is in all probability proportional to this rather than to the amount of solvent. It seems clear that 1 gm. of hide-powder for each 0.1 gm. of total extract is the outside quantity required, and it would be well to try whether this could not be still further reduced. 1 gm. of hide would ultimately absorb nearly 1 gm. of tannin, so that the question is simply one of time. As, however, the last traces of tannin in a dilute infusion will penetrate very slowly through a surface of tanned hide, rapid action with small quantities of powder will probably be best attained by successive additions, or on the filter principle. Rapid action is important, not only to save time, but because in warm weather putrefactive changes soon occur, and increase solution of the hide.

The practical limits of strength are closely approached by the Vienna chemists on the one hand (1.2 per cent. total extract), and by Von Schroeder and Koch (0.4 per cent.) on the other.

A practical difficulty of the hide-powder filter arises from the fact that some samples of powder are so water-repellent as to be wet with great difficulty, and to filter mainly up the sides of the tube, leaving the centre of the powder unused. Another arises from the fact that the filtrate progressively changes in composition; the first 25 cc. containing most of the soluble matter from the powder, and least of gallic acid and other matters which are loosely absorbed, while in successive quantities these conditions are gradually reversed. Probably a combination of maceration and percolation on the principle of Mr. Palmer's method would be satisfactory, but as it is impossible *completely* to get rid of the liquor used to wash the powder, it would be better to retain the whole and make a suitable correction for solubility.

The correction for solubility is generally obtained by making a blank experiment with pure water. This, as several of my correspondents point out, is wrong in principle, since much of the soluble matter is precipitated by tannin, and hence the solubility in water is much greater than in liquor. Mr. Bertram Hunt makes the correction by a blank experiment with water, and after drying and weighing, redissolves and precipitates with slight excess of tannin, and collects on a tared filter. Half the weight of the tannate so obtained is deducted from the total residue. The absorption of tannin with hide-powder is so conducted as to leave no matter precipitable by either tannin or gelatin in the filtrate. This method is correct in principle, and deserves general adoption, and as the determination can be made once for all on a good stock of hide-powder, is very little trouble.

The amount of organic matter dissolved even by pure water from a good hide-powder employed as a filter

(7 grms. to 100 cc.) has been shown by Dr. Koch† not to exceed 0.004 grm. in 50 cc., though most commercial sorts leave much more. He points out the importance of using powder which has not in any stage of the process undergone putrefaction, not only on account of the solubility of the decomposition products, but because such powders absorb a larger proportion of colouring matter than those of pure hide fibre.

A point which requires attention is the temperature at which water should be determined, and the residues should be dried. This ranges among my correspondents from that of the ordinary water oven to 110° C. The time of drying is greatly abridged by the use of a temperature above boiling point, and it probably yields more constant results. With many tanning materials the difference in results is immaterial, but the catechin of gambier not only loses its water of crystallisation, but is according to Ettli‡ converted slowly at 100° (or even at ordinary temperatures in vacuo) into catechutannic acid with loss of a molecule of OH_2 . This reaction is rapid and complete at 127° C., and the next anhydride is only found at a considerably higher temperature. It is desirable to choose a temperature at which the change is rapid and practically complete, since black gambier takes days to arrive at a constant weight in the water oven. If catechin is to be estimated as tannin, there is no objection theoretical or practical to weighing it as such. It is desirable that experiments should be undertaken to determine the most satisfactory drying temperature, not only for gambier but other materials.

I shall be extremely obliged for further information on these and other points, so as to enable me to outline at an early date, a method which will represent as nearly as possible the average of chemical opinion. I am making a similar appeal to American and continental chemists, and am simply acting as secretary to the informal "Commission." I have to thank many chemists for information besides those named in the foregoing, but whose methods are practically identical with one or other of those quoted.

Journal and Patent* Literature.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

The Destruction of Lead Pipes. Jour. I. Gasbeleuchtung, 34, 175.

The following communication by K. Hartmann, published in the "Gesundheits-Ingenieur," purposes to draw the attention of technical men to the damages caused to lead-work by the larva of a woodworm. Recently, when tracing the leaky places in a lead pipe, a live woodworm was found in one of the leaks, with its head protruding in the wall of the piping. The outer opening of the cavity was of oblong form, measuring 7 mm. by 4 mm., and the inner

surface of the same showed fine indentures. Similar cases are not unknown and have occasionally found their way into literature. Thus it is mentioned in Kerl and Stohmann's "Handbook of Technical Chemistry," that certain woodworms (*Sirex gigas*) perforate sheet lead, the holes produced showing a rough surface with fine indentures. At the "Muldener Hütte" holes up to 6.5 mm. diameter were caused in sheet lead, the same being affixed to timber-work. As the woodworm, which belongs to the family of the *Coleoptera*, works its way from the sap of the timber towards the bark, and from thence into the lead, it is proposed to so place the timber that the bark may be furthest removed from the lead.

Schenrer-Kestner (Compt. Rend. 53, 518) has published a case in which cylindrical holes were found in the lead lining of a beam of a new vitriol chamber, and this only a few days after effecting the covering. In one of the holes the semi-developed body of an insect was found, partly in the lead, and head first. The diameter of the perforation corresponded exactly to the body of the insect, so that the latter could not turn round in order to escape.

Similar observations having been made by others, the author does not doubt that in the case mentioned first the corrosion was caused by the woodworm.—H. A.

PATENTS.

Improvements in and relating to Apparatus for Evaporating Solutions containing Salts and for other Liquids. J. Foster, Sunderland. Eng. Pat. 9518, June 19, 1890. 8d.

This invention relates to improvements in multiple-effect evaporating apparatus, more especially to modifications of some of the designs described in a previous patent, Eng. Pat. 7343 of 1889 (this Journal, 1890, 593). They refer to details of the construction of the vertical tubular evaporating vessels, embracing the provision of lower conical ends to the same, and outlets for the collection of the concentrated liquor or the deposited salt, and the fitting of automatic rotary valves to the outlets for withdrawing the contents at regulated intervals. Also the application of central rotary stirrers for agitating the liquid and for preventing deposit on certain surfaces. There are three claims and two illustrations.—B.

Improvements in or relating to Apparatus applicable for the Extraction of Fats or Oils, Sulphur and other Material, and for Manufacturing Extracts for Dyes and other Purposes. A. J. Boulton, London. From "G. Boulton fils, Douard and Contamine," Rouen, France. Eng. Pat. 9825, June 24, 1890. 8d.

The apparatus consists of two boiling vessels, surmounted by two receivers or "displacers," from each of which the extract or solution is led into the opposite boiling vessel. The receivers, which are provided with water and steam pipes and with filling holes for the material to be extracted, have internal false bottoms, perforated and placed at an inclination, which act as filters for the descending liquor. The extracted liquor passes into the opposite boiler as described, and may there be heated by steam or otherwise. The rising vapour reaches the receiver overhead, where it condenses, and both heats and extracts the soluble parts from the surrounding substances. The solution passes through the filter into the other boiler, where it may be withdrawn or mixed with other liquids or extracts, with or without the admission of heat. The boilers are used alternately, and provision is made for the condensation of all excess vapour whether arising from boilers or receivers, and its return to the apparatus. The inventors claim that with this arrangement they succeed in preventing all loss of vapour or volatile liquids and in avoiding all danger from fire. For details the specification should be consulted, which embraces four claims, and is illustrated by two drawings.—B.

* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d.	3d.
Above 8d., and not exceeding 1s. 6d.	1d.
" 1s. 6d., " " 2s. 4d.	1½d.
" 2s. 4d., " " 3s. 1d.	2d.

Plates for Oil and other Presses. W. C. Leechman, Colombo, Ceylon. Eng. Pat. 9526, July 19, 1890. 6d.

See under XII., page 708.

Improvements in Glass-lined Tubing. D. Rylands, Stairfoot, and K. Morant, Barnsley. Eng. Pat. 11,714, July 26, 1890. 6d.

THE object of this invention is two-fold: (1) the manufacture of glass-lined tubing, so that in the one tube there can be two or more tubes inserted, thus enabling one or more complete circuits to be secured by means of one metal tube thus lined; and (2) in the mode of coupling up unprotected glass tubes. In the former the metal pipe is somewhat like a double-barrelled gun, with an outside flange at each end, and the glass tubes are inserted in each barrel with suitable packing to keep them in position, and to enable them to resist pressure. After insertion in the tube the ends can be ground down level with the faces of the flanges, and the whole can be coupled up by bolts and suitable washers.

In unprotected glass tubes, the tubes are formed with angular interrupted projections at each end. A metal flange is threaded on each tube, and the two flanges are rotated till the projections on the flanges bear on those of the tubes; a suitable ring being now inserted they can be drawn together and secured by bolts.—E. S.

Improvements in Refrigerating Apparatus. H. Imray, London. From "Compagnie Générale pour la Production du Froid (procédé E. Fixary)," Paris, France. Eng. Pat. 12,896, August 16, 1890. 8d.

IN Eng. Pat. 2387 of 1885 the thawing of the rime from the circulating refrigerating pipes was described as being mainly effected by the circulation of the comparatively warm air when arriving in the first compartment of the refrigerating apparatus. In this invention, while the temperature of the air to be refrigerated can be reduced to a very low degree, depending on the temperature at which the liquefied gas (as ammonia, &c.) evaporates, the melting of the rime is effected by the refrigerating fluid itself after compression. The apparatus consists of two chambers, through which air is circulated by a fan. Each chamber contains a set of the refrigerating pipes, placed one above the other, and the coils of each chamber are connected by branches with shut-off cocks, with the supply conduit for liquefied vapour; with the exhaust conduit leading to the compressor; and also with the compression conduit of the compressor, the melting of the rime off the coils being effected by admitting the warm vapour from the compressor, which being done, the conduit for liquefied vapour is shut off from the second set of coils, and the liquid in the first set is made to expand into the second set.—E. S.

Improved Apparatus for Evaporating and Distilling Liquids. R. Harburn, Sunderland. Eng. Pat. 13,322, August 25, 1890. 8d.

THE object of this invention is to evaporate and distil liquids by aid of steam in one or more chambers, in which the pressure is practically reduced below that of the atmosphere. The chambers have outlets to a condenser and to a pump which carries off any matter not intended for evaporation. The method consists in admitting the steam and liquid into a special mixing apparatus, so arranged that the steam comes in contact with the liquid immediately before it enters what is called the evaporating chamber. In the chambers suitable plates are fitted for intercepting matter not intended for evaporation or distillation, such matters being carried away by the pump, the evaporated and distilled portions being conveyed to the condenser by suitable connections. In order to understand the

construction and working of the apparatus, the drawing attached to the specification must be consulted. The invention may be applied to various purposes, among others to the manufacture of sugar, the separation of salts and alkalis in chemical manufacture, and the purifying of sea-water for use in marine engine boilers.—E. S.

Improvements in Filtering Materials and Filters. E. Edwards, London. From O. Arlt, Goerlitz, Germany. Eng. Pat. 8440, May 16, 1891. 8d.

THE filtering materials consist of inorganic substances of various densities and quality, arranged in layers one above another in such a way that the lowest, loosest and coarsest layer is surmounted by a finer layer, and so on, to the uppermost, which is finest of all. The raw materials employed are—(1) slag wool or silicate cotton; (2) clean, white, long-tailed asbestos; and (3) ordinary asbestos in the form of the finest fibre. After undergoing certain treatment these are made into different mixtures, according to the layer each is intended to occupy in the filter. This is a cylindrical vessel made of sheet copper or other metal, and is supported on legs. When full the filtering materials are covered by a perforated plate, over which is the tight-fitting cover. The liquid to be filtered is admitted through a cock at the bottom, and discharged through another at the top. Several modifications of the filter are shown on the drawing accompanying the specification.—E. S.

Improvements in Evaporating and Distilling Apparatus. W. J. Mirrlees, Glasgow. From H. T. Yuryan, Toledo, Ohio, U.S.A. Eng. Pat. 8809, May 23, 1891. 11d.

IN previous patents relating to multiple-effect evaporating apparatus (Eng. Pats. 14,162 of 1886 and 213 of 1888; this Journal, 1887, 39; and 1888, 313), the increasing volume of the vapour passing through the coil during the process of vaporisation was met by a gradual increase in the diameter of the tubes from the inlet to the outlet of the coil. But as the surface of a tube does not increase at the same rate with an increase of diameter as its contents, it was found that the effective heating surface diminished relatively to the contents of the coil. The present invention seeks to obviate this objection by dividing the tube constituting a coil into succeeding series of tubes, preferably all of equal diameter, each following series having a larger number of tubes than the preceding one. The series may be either super-imposed with suitable end pieces or connected end to end as indicated in two sheets of drawings. There are three claims.—B.

II.—FUEL, GAS, AND LIGHT.

The Gasification of Tar. Merckens. Jour. f. Gasbeleuchtung, 34, 188. From the Society of Baltic Gas Engineers.

By injecting into a red-hot retort half filled with coke a spray of tar by means of a Körting's jet supplied with superheated steam, the author has succeeded in converting the whole of the tar into gas, without leaving any residue in the retort. The gas had a high candle-power, and in this way he has been able to avoid the use of expensive enriching material. On conclusion of the experiments, the author hopes to furnish further details.—F. H. L.

The Dinsmore Process of Gas Manufacture. G. Kraemer. Jour. f. Gasbeleuchtung, **34**, 225—228. (Compare this Journal, 1890, 444—447.)

ACCORDING to the author, the experiments which were carried out in Liverpool, and reported in the Journal of Gas Lighting for February 17, 1891, must be taken as proving conclusively that this process possesses no advantages whatever over the usual method of procedure, but seeing that it still excites considerable interest—like the problem of perpetual motion—he submits the following considerations from the purely chemical point of view:—

As improved by Carr, the process consists in passing the whole of the products of the distillation of the coal, tar, and liquor, as well as gas, through an empty retort before entering into the hydraulic main. Of the constituents of the gas, the only substances affected by the treatment are methane and the olefines. The action on the benzene and naphthalene will be considered with the tar. Berthelot (*Annalen*, **142**, 251) has proved that by passing through a red-hot tube, methane and ethylene are converted into acetylene and hydrogen, the former being at once polymerised into benzene, &c.; the decomposition, however, is never complete, traces of ethane and its homologues being produced. Seeing that these hydrocarbons form only about 40 per cent. of the gas, and that it is impossible owing to the speed of its passage through the retort, and to its being a bad conductor of heat, for the action to be anything like complete, the increase in volume is small, and being due partly to benzene and its homologues, is in part only temporary. Watson Smith (this Journal, 1890, 444—447) has stated that the increase in volume may be as much as 10 per cent., and as this amount can hardly be obtained from the gas, it is necessary to consider the action of the constituents of the tar. Benzene and its homologues are split up in part under this treatment into diphenyl, anthracene, naphthalene, &c., and free hydrogen, but as in 100 kilos. of tar only 2.5 kilos. of naphthalene are found, to the corresponding volume of gas (600 ccm.), an increase of only 4 ccm. or 0.66 per cent. may be expected. If the phenols are decomposed in a similar manner, the latter figure may reach 1.0 per cent. The naphthalene is practically unaltered, and from the heavy hydrocarbons only small amounts of hydrogen are given off. From 100 kilos. of the heavy oils, 10 ccm. of gas may be obtained, a figure agreeing partly with the results obtained by the author in the works at Grabow and Erkner; this gas, however, is much poorer in hydrocarbons than that derived from the naphtha. If these figures are added together and calculated on the yield of gas, it will be found that an increase in volume of hardly 0.5 per cent. may be expected from the gasification of the tar.

With regard to the alleged increased candle-power, the original gas contains, together with 47 per cent. of hydrogen, about 40 per cent. by volume of gaseous hydrocarbons, which latter have the property of keeping considerable amounts of benzene and naphthalene in suspension, thus materially increasing the illuminating power. The increase in volume, by the process under consideration, being, the author thinks, only at the expense of the methane and olefines, the 40 per cent. of hydrocarbons is greatly reduced, and hence far less benzene and naphthalene can remain suspended, the nett result being of necessity a loss of illuminating power.

Experiments carried out on the large scale are considered by the author to show that the statement that by heating two molecules of cresol and one of phenol, one molecule of anthracene, one of benzene, and three of water are formed, is only in part correct (compare this Journal, 1890, 447). From 100 kilos. of cresol he obtained 19.9 ccm. of gas of average illuminating power and 76.1 kilos. of tar, the tar containing 9 per cent. of benzene, 20.9 per cent. of crude phenol solidifying at 23°, 46.6 per cent. of unchanged cresol, and 23.3 per cent. of hydrocarbons of high boiling point, with little anthracene but a large amount of phenanthrene. That is to say that hardly 10 per cent. of the cresol was decomposed according to the formula.

From the adoption of the Dinsmore process, therefore, an increase in the volume of the gas may be expected, but this only at the expense, it is thought, of the gaseous hydrocarbons, which are not only valuable in themselves as a source of light, but confer upon the gas its property of holding in suspension the various liquid and solid hydrocarbons to which a large proportion of its illuminating power is due. The author believes this process gives results in no way different from those obtained by employing a higher temperature of carbonisation, the advantages of the higher yield of gas being in his opinion neutralised by the trouble caused by tar stoppages in the ascension pipes and naphthalene stoppages in the mains.—F. H. L.

Detection of the Sulphur not combined with Hydrogen in Illuminating Gas. "L. Hovay de N. Hovsa." Bull. Soc. Chim. 1890, **4**, 714—715.

Fuel for the Hefner Lamp. Jour. f. Gasbeleuchtung, **34**, 265—266.

A DISCUSSION on the subject of amyl acetate, the fuel of the Hefner lamp, has recently taken place; it was originated by Voller, who, in carrying out some photometric observations with the lamp, used a sample of amyl acetate, obtained from a Hamburg druggist, which boiled at 80° instead of 138° and consisted of a mixture of amyl acetate and alcohol. As the photometric determinations gave erroneous results, Voller questioned the advantage of using the Hefner lamp as a standard light instead of candles (*Electrotechnischen Zeits.* 1891, 122), owing to the variability in composition of commercial amyl acetate.

Hefner-Altenek replied as follows (*Ibid.* 177):—As the Hefner lamp has been only recently unanimously adopted as a standard by the "Deutschen Vereins von Gas- und Wasserfachmännern," and as, moreover, it is usually employed as such in electro-technology, Voller's remarks must not be allowed to pass unnoticed; there is no difficulty whatever in obtaining reliable samples of amyl acetate if the pure compound is ordered and the exhaustive experiments of Liebethal (*Ibid.* 1883, 583 and 610) have shown that the lamp is an excellent unit and does not require that the amyl acetate should be chemically pure. It is essential, however, in making photometric observations with the Hefner lamp, to do so in fresh air, especially in testing the illuminating power of incandescent lights, as an increase in the proportion of carbon dioxide in the air affects very materially the illuminating power of all flames.

The following are some simple tests by which the presence of impurities in ordinary commercial amyl acetate can be detected. (1.) The specific gravity should be 0.872—0.876 at 15°; if it is less than 0.872, alcohol, amyl alcohol, amylene, &c., may be present. (2.) The sample should mix with its own volume of benzene or carbon bisulphide without any turbidity being produced; if not, it is probable that the sample has been adulterated with aqueous alcohol or aqueous amyl alcohol, to increase the specific gravity. (3.) On shaking 1 cc. of the sample with 10 cc. of alcohol of 90 per cent. (Tralles) and 10 cc. of water, a clear solution should result; if a turbidity is produced, amylene, toluene, &c. are probably present. (4.) A drop of the sample placed on white paper should leave no permanent grease-spot on evaporation; this test proves the absence of fats and high-boiling coal-tar oils. In addition to the four tests given above it is advantageous to determine the boiling point, which should be 136°—142° under a pressure of 760 mm.—F. S. K.

—T. L. B.

Coke Breeze as Fuel. G. Fèvre. Compt. Rend. de la Soc. Tech. de l'Ind. du Gaz en France, 1890, 108; Proc. Inst. Civil Eng. Abstracts, **105**, iii., 59—60.

The fuel value of coke-breeze depends upon its composition, which varies according to the source from which it is derived. That produced from breaking coke consists of—

	Per Cent.
Moisture	5
Carbon	84
Ashes and clinkers	11

and that from coke direct from the retorts—

	Per Cent.
Moisture	13.5
Carbon	79.0
Ashes and clinkers	16.5

The average composition of the "Pas-du-Calais" coal, generally used in the gasworks of the North of France, is—

	Per Cent.
Moisture	1.5
Carbon and volatile matters	88.0
Ashes and clinkers	10.5

Taking the percentage of carbon in each of these cases, and assuming the coal worth 16s. per ton, this would give the value of the breeze from the coke breaker as equal to 15s. 3d. per ton, and that from the retorts to 12s. 9d. per ton, the lower value of the retort breeze being chiefly due to the larger percentage of moisture it contains.

At some gasworks the coke breeze is made into bricks, to be used for generating steam or for heating the retort furnaces, but if the breeze is worth 6s. to 7s. per ton, and its conversion into "briquettes" costs about the same sum, coal at 15s. per ton would be preferable, as the manufacture of "briquettes" requires expensive machinery.

The direct use of breeze as fuel has for some years attracted considerable attention, and, with special appliances, it has been utilised successfully either alone or with a mixture of coal. Of such appliances reference may be made to the Perret furnaces, which are now extensively used. The cathedral of St. Quentin was heated during the winter of 1889 by eight of these furnaces, burning only coke-breeze. The cubical contents of the church are 3,178,530 cubic feet, and during five winter months, which

included 65 days of frost, the average temperature in the church was maintained at 52°·6° F., as compared with an average external temperature of 36°·5° F. The average daily consumption of breeze was 3,053 lb., which, at 6s. 5d. per ton, would cost 8s. 9d. per day. The system is also employed for steam boilers.

The author has also experimented for two years with a mixture of coke-breeze in a generator retort-furnace with the following results:—

With a mixture of half breeze and half small coal, and with the air-supply under pressure, and a consumption of 30 cwt. of the mixture per 24 hours, the result was unsatisfactory, as the temperature was not maintained sufficiently high for the proper carbonisation of the coal. When the air-supply under pressure was done away with the furnace worked well, a slight vacuum being maintained in the generator and a slight pressure at the top of the furnace. The coke-breeze used was from the coke-breaker, on account of the smaller quantity of water it contained; the breeze was very fine, having passed through a screen perforated with holes of about $\frac{1}{4}$ in. diameter. It was not considered practicable to use coke-breeze alone, because it would not agglomerate, and the furnace bars would have been obstructed by it. The fuel was put into the generator every hour in quantities of 61 to 66 lb. Twenty minutes after filling the generator the mixture was raised with a bar and the lumps pushed to the back of the generator, the firing proceeding in a manner similar to that with coke. For one month a mixture of 40 per cent. by weight of small coal and 60 per cent. of breeze was used, and of this 32 lb. were required to carbonise 220 lb. of coal. During the next month, with 35·8 per cent. of small coal and 64·2 per cent. of breeze, the rate of consumption was 30 lb. of fuel per 220 lb. of coal carbonised.

The following comparisons will show the estimated cost of heating a bench of seven retorts, carbonising five tons of coal in 24 hours, with coke or with small coal:—

	s.	d.	s.	d.
(1.) 7½ bushels of coke at 43s. 6d.			27	0
(2.) 2,204 lb. small coal	16	0		
Extra labour	1	2½		
			17	2½
(3.) 540 lb. small coal at 16s.	3	11		
1,003 lb. breeze at 6s. 5d.	2	10½		
Extra labour	1	2½		
			8	11

If, as is the case in some works, the coke-breeze is of little or no value, the economy would be greater, but if, on the contrary, it can be sold for more than 6s. 5d. per ton, the economy would be proportionately reduced.

The Utilisation of Coke-Breeze. Compt. Rend. de la Soc. tech. de l'Ind. du Gaz en France, 1890, 358; Proc. Inst. Civil Eng. Abstracts, 105, iii., 61--63.

At the meeting of the society at Paris in June 1885 the author read a paper upon a system of heating gas-furnaces with coke-breeze. So far it has not been found possible to use breeze alone for heating gas-furnaces, but where there is not an easy sale for the small coke good results may be obtained by leaving it with the breeze. With breeze alone the quantity of clinker was so great that it formed an impenetrable layer on the furnace bars, the air-supply found passages in various parts, the combustion became imperfect, and the heats fell off.

The following proportions of various fuels were found necessary for heating a bench of retorts for 24 hours:—(1), 49½ bushels of coke-breeze and 16½ bushels of coke; (2), 55 bushels of coke-breeze and 13¾ bushels of small coal; (3), 30½ bushels of small coal and 5½ bushels of coke; (4), 82½ bushels of large coke, but in cases 1, 2, and 3 only 10,582 lb. of coal were carbonised, while in case 4 the quantity was 11,905 lb. of coal. Also in cases 1 and 2, 2¾ bushels or 198 lb. of small coal and 4½ bushels of coke-breeze were required for the production of a forced draught by steam. A breeze furnace wears out more quickly than an ordinary furnace, the additional cost for which is shown to be 13d. per furnace per day. The breeze furnace is fired every 15 to 20 minutes and clinkered every four hours, which occupies six to 10 minutes, a special rake being used to push the fuel to the back of the furnace, as, without this, the clinkering would be more difficult than with an ordinary furnace. The clinkers do not adhere to the bars, but stick more firmly to the sides of the furnace; the furnace-bars are not injured, being found in the same condition when a furnace is let down as they were when put in, the air and steam keeping them always cool. It was expected that there would be deposits of ashes in the flues and chimney, but during five years' working no unusual deposits have been found.

The volume of air forced into the furnace by the injector varied between 23,993 cubic feet and 26,811 cubic feet per hour. Theoretically 1 lb. of carbon requires 142¾ cubic feet of air for complete combustion, and taking case No. 2 before referred to, the breeze and small coal would weigh about 3,417 lb., or, deducting the residuals, the net weight of the carbon would be 2,885 lb., and the theoretical quantity of air for this would be 411,833 cubic feet. Taking account of the partial or total stoppages for clinkering, and also of the carburised hydrogen in the small coal, it will be seen that there was not an excess of air, as, with a chimney draught, it is generally assumed that the air necessary for combustion is double the theoretical volume.

From analyses of the products of combustion it appears that, shortly after the furnace is charged, few of the combustible elements are lost, and that a constant condition is attained until the time for clinkering, and under this condition 4 per cent. of carbonic oxide and 4 per cent. of hydrogen escape in the chimney; the absolute absence of oxygen also indicates an insufficient air-supply.

In consequence of the enormous quantities of breeze which accumulate in a gasworks with the increasing demand for broken coke, many gas managers may be interested in the use of this system, and the selling prices of coke and breeze and the cost of coal at any works being known, a very simple calculation will enable them to decide whether there would be an advantage in doing so.

Trials were also made with firing two 30-H.P. Babcock and Wilcox steam boilers with coke-breeze and small coal, using a forced draught obtained by means of a Bourdon steam-blower. The results are given as follows:—

(1.) WITH SMALL COAL AND BREEZE.

Length of trial.....	10 hours.
Average steam pressure.....	6 atmospheres.
Water evaporated.....	14,109 lb.
Small coal used.....	1,898 lb.
Breeze used.....	467 lb.
Normal horse-power.....	2,365 H.P.
Actual power developed.....	30 H.P.
	42'66 H.P.

(2.) WITH SMALL COAL AND BREEZE.

Length of trial.....	6 hours.
Average steam pressure.....	6 atmospheres.
Water evaporated.....	7,584 lb.
Small coal used.....	856 lb.
Breeze used.....	587 lb.
Normal horse-power.....	1,443 lb.
Actual power developed.....	30 H.P.
	36'39 H.P.

(3.) WITH SMALL COAL AND BREEZE.

Length of trial.....	6 hours.
Average steam pressure.....	6 atmospheres.
Water evaporated.....	5,621 lb.
Small coal used.....	370 lb.
Breeze used.....	794 lb.
Normal horse-power.....	1,164 lb.
Actual power developed.....	30 H.P.
	28'33 H.P.

(4.) WITH SMALL COAL AND BREEZE.

Length of trial.....	6 hours.
Average steam-pressure.....	6 atmospheres.
Water evaporated.....	5,556 lb.
Small coal used.....	326 lb.
Breeze used.....	810 lb.
Normal horse-power.....	1,175 lb.
Actual power developed.....	30 H.P.
	28 H.P.

The proportions of small coal and breeze given in the last example may be taken as the limit for practical working.

PATENTS.

Improvements in Apparatus for and in the Manufacture of Water-Gas. S. Fox and E. Blass, Leeds. Eng. Pat. 6131, April 10, 1889. (Second Edition.) 6d.

In order to obtain the steam necessary for the production of water-gas without the aid of a steam boiler, water is admitted under pressure into a heated regenerator and there converted into steam.—F. S. K.

Improvements relating to Apparatus for Burning Liquid Fuel. W. E. Smith, Brighton. Eng. Pat. 9604, June 20, 1890. 1s. 6d.

The patent refers to a means for burning liquid fuel in which the "atomised" fuel is mingled with heated air in such a manner that combustion complete and well under control can take place. To this end an injector fixed in a cylindrical or other shaped chamber, which is surrounded by a similar larger chamber, is used to atomise the fuel, the air for its consumption being drawn in through the annular space between the two cylindrical chambers and thereby heated. The heating is promoted by the use of a steam coil situated in the annular chamber and supplied with steam from the boiler to be fired; the steam may be superheated before its entrance into the coil, and also on its passage from the coil to the injector, which is its ultimate destination. The heating and mixing effects are enhanced by the employment of baffle plates, wire gauze, &c. to break up and commingle the streams of gas and vapour about to be consumed. Various modifications of the apparatus,

such as the use of U-pipes projecting into the combustion chamber, through which the air is made to pass before consumption, and the hinging of the whole apparatus so that it can be swung back from the combustion chamber upon occasion, are described and illustrated, as are also particular applications to an ordinary single flue Cornish boiler and a locomotive boiler. In the last case a fire-brick lining and fire-brick perforated hood distribute the heat so as to avoid injury to the tube-plate or tubes.

—B. B.

Improvements in and relating to Apparatus for the Manufacture of Gas for Illuminating and other Purposes. J. Love, Stratford. Eng. Pat. 10,329, July 3, 1890. 11d.

THE most important feature of this invention is that the apparatus is entirely self-contained, the water-gas, hydrocarbon gas, and the steam necessary for the production of the water-gas and for working various mechanical arrangements, being all generated in one retort; a considerable economy in space is thus effected and the apparatus is more easy to work, and requires less labour than other gas producers.

The vertical, somewhat bottled-shaped combustion chamber in which the fuel is placed is surrounded by an outer shell or annular space, partially filled with water, the whole apparatus being similar in form to an ordinary vertical boiler. The combustion chamber is charged from above by a mechanical arrangement, consisting of an endless screw or elevator enclosed in a cylindrical casing, and worked by a small steam engine securely fastened on to the side of the outer shell of the retort; the charge is introduced into the combustion chamber with the aid of a suitable feed-hopper, fitted with an air-tight cover. The hydrocarbon is placed in a chamber situated near the bottom of, and partially surrounding the retort, the chamber being fitted with trays and wicks, and also with a coil through which steam or hot water is passed to vaporise the liquid.

There are eleven claims and two sheets of drawings.

—F. S. K.

Improvements in the Composition and Manufacture of Fuel from Coal Dust and similar Material. W. H. Buckland, South Hayling, and G. Myers, Hampstead. Eng. Pat. 11,239, July 18, 1890. 6d.

INSTEAD of using pitch to cement coal-dust together to form briquettes, the patentees employ "substances of a glutinous or farinaceous character, such as are obtained from wheat, barley, rye, or other cereals or vegetables, 5 per cent. to 25 per cent. of coal-dust being a suitable proportion. The mixture may be kneaded by hand and set in a short time, so that moulding under pressure is unnecessary, though the use of moulds may be adopted to aid rapid manufacture. It is claimed that the product burns with less smoke than the ordinary briquettes, and is more economical in use. Ashes or refuse matter from coal fires with or without fresh coal may also be utilised.

—B. B.

New or Improved Apparatus for Drawing Coke from Coke Ovens. C. W. Bartholomew, Towcester, and J. Oxley, Wombwell. Eng. Pat. 12,780, August 12, 1890. 8d.

THIS apparatus for drawing coke from coke ovens cannot be properly described without the aid of drawings; the principal feature of the apparatus is the use of a suspended working lever, arranged to reciprocate and work a coke-drawing fork.—F. S. K.

Improvements in the Production of Coke and in the Apparatus Employed therefor. M. Fromont, Brussels, Belgium. Eng. Pat. 13,177, August 27, 1890. 8d.

THIS invention has for its object the improvement of coke furnaces in such a way that coke can be produced from coal containing little or no fatty substance or oil, and from coal or lignite briquettes or other fuel; this object is attained by burning practically the whole of the escaping volatile matters upon the walls of the coking chambers.

The coking chambers, which are arranged in juxtaposition alternately, and on different levels, are first heated to incandescence and then charged with coal through feeding channels. The gases evolved from the heated coal pass through hollow doors or ports into "heat-restoring chambers" placed below the coking chambers, and containing fire-proof blocks or partitions; here the combustible gases encounter air, previously heated in conduits or pipes, and such intense heat is produced that the duration of the carbonising process is considerably shortened; the excess of heat is also stored up so that when carbonisation is at an end the apparatus is ready for a fresh supply of material.—F. S. K.

Improvements in the Methods of Setting Clay Retorts for the Manufacture of Coal-Gas. T. Cooke, Bristol. Eng. Pat. 17,745, November 5, 1890. 6d.

FOUR through retorts, 18 to 20 ft. long, are set in one arch and heated by direct firing by means of four shallow coke furnaces, two of which are placed beneath the retorts at each end of the arch; or, eight retorts 9 to 10 ft. long, having only one mouthpiece each, are fired directly by two such furnaces placed in a similar position. In either case the retorts are set in three tiers, three in each of the bottom tiers and two in the top one, and are supported on brick piers with apertures between them allowing a free circulation of the furnace gases.

The heating can be effectually accomplished, consuming not more than 30 per cent. of the coke produced in the retorts.—F. S. K.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

Terpene from Compressed Gas Oils. A. Étard and P. Lambert. Compt. Rend. 112, 945—947.

POURABLE or compressed gas is prepared in France from the heavy paraffinoid oils obtained from the bituminous schists of Autun or less frequently from material similar to Scotch boghead. The oils are carburised at a cherry-red heat in long cast tubes, and the resulting gas is compressed in cylinders; in this operation light liquids condense holding in solution such gases as butylene, ethylene, &c. The authors have examined the gas oils obtained from both the above sources and find them practically identical. They distil between 20—360°, leaving a tar, and yield about 60 per cent. of benzene, 10 per cent. of toluene, 6 per cent. of light unsaturated hydrocarbons, and 10 per cent. of higher oils between 110—190°, which give no definite boiling point, but undergo steady decomposition at about 167°. Repeated fractionation of the light oils thus produced yielded a product $C_{12}H_{22}$, boiling point 42·5, density 0·803, vapour density 2·45 (theory 2·35), named by the authors *parapentylene*; it has the principal terpene properties. It has a peppery taste and characteristic odour, is not acted on by ammoniacal silver or cuprous salts, but ammonia potassic solutions of silver deposit silver mirrors in its presence. Concentrated aqueous silver nitrate produces a white crystalline precipitate; aqueous sulphurous acid forms

with it white crystals of the composition $C_{10}H_{12} \cdot 2H_2SO_4$ insoluble in almost all reagents except alkalis, and which exhibit a remarkable tendency to retain small quantities of iron. Halogen acids resinise it rapidly or cause it to explode, oxidising agents even when dilute destroy it completely, whilst bromine gives rise to liquid derivatives. In the cold it gradually polymerises, the density increasing regularly with the time of exposure, ultimately forming a solid, $C_{10}H_{12}$, melting at 8° with a density 1.003 and called *di-pyropentylene* which depolymerises on heating. Pyropentylene is neither identical with valylene nor perylene.

—D. A. L.

Paraffin and Bitumen in Brown-Coal Tar. E. von Boyen. *Zeits. f. angew. Chem.* 1891, 261—265. (Continued from this Journal, 1891, 455.)

THE author has tried a large number of experiments on the possibility of preparing crystalline paraffin from the tar without distillation; but neither by the action of pressure alone, nor by caustic soda, nor by sulphuric acid followed by pressure, were the results satisfactory. The best yield was given by the following process: The tar was treated with 6 to 8 per cent. of caustic soda ($40^\circ B.$) at a temperature of 60° , and the top layer of the liquid, containing the hydrocarbons separated, cooled, and pressed. The cake was melted with 3 to 6 per cent. of purified creosote oil (boiling point 200°) and another 3 per cent. of soda added; after separation, the crude paraffin was dissolved in 40 per cent. of paraffin oil and treated with 4 per cent. of sulphuric acid at a temperature just above the solidifying point. This latter process was repeated twice, and the paraffin separated.

Of methods involving distillation a large number are given, which may be divided into two classes: 1st, those in which the tar is first washed and finally distilled; and 2nd, those in which the distillation precedes the washing. Of these, for the details of all of which reference must be made to the original article, the author recommends, in the case of tars containing less than 5 per cent. of bitumen, that the tar be treated with sulphuric acid, the oils separated, washed, and distilled under atmospheric pressure, and the resulting paraffin purified by pressure at a temperature of 2° . The great majority of tars containing more than 5 per cent. of bitumen, the use of alkali becomes harmful, owing to the great loss and the difficulty of working up the dissolved substances, and the best process is to distil the tar under atmospheric pressure and to refine the paraffin by a second distillation *in vacuo*. (See also this Journal, 1890, 487.)—F. H. L.

The Coal-Tar Industry during the Year 1890. Jour. f. Gasbeleuchtung, 34, 185—188.

THE past year has been, on the whole, a favourable one for the coal-tar industry, the prices of most of the different products having risen considerably. Phenol, however, has been the single exception, having probably passed its maximum demand. Benzene has risen in value nearly 25 per cent., and this increase is likely to be maintained, owing partly to its increased use, and partly to the fact that the amount of benzene in the tar is steadily diminishing, and threatens to become very small if the Dinsmore process is largely adopted. Naphthalin is stronger, having found more outlets in the colour works. Anthracene remains much as usual. The prices of ammonium sulphate depend more on the sodium nitrate trade than on the value of the coal, and no improvement is likely to be experienced. Pyridine bases for denaturing spirit have also increased in price about 25 per cent., being employed for this purpose in Germany, Austria, Switzerland, and, according to report, Sweden.

The most important factor in the phenol market has been the success on a manufacturing scale of the process for its synthetical production. This substance has now been known long enough to be recognised as of the best quality. The exact process employed in its manufacture is unknown, but whether it is made from benzene sulphonic acid, or

aniline, benzene must always be the starting point, and therefore the process is only workable when the latter is considerably below phenol in price. The further advantages claimed for the synthetical product, viz., greater purity and non-colouration in the light, do not apply, for the second claim is contrary to fact, and it is possible with only slight loss to prepare from tar a phenol equally pure. Much work is apparently being done on the purification of this substance, this being due to the constant demands of the market for greater purity at a lower price, and to the Pharmacopœia Commission, who demand an article far purer than there is any occasion for.

The only purifying process which has been made public is that of Richm (D.R.P. 53,228 and 53,307), which depends on the separation of the phenol as a barium salt. According to the inventor it is possible by this process to separate also the three isomeric cresols. On a manufacturing scale, however, this process becomes impracticable, owing to the insolubility of the barium, which necessitates the employment of such large quantities of water. Whether there is any opening for the separated cresols remains to be seen.

Among the new substances discovered in tar may be mentioned eumarene and indole (Ber. 23, 78—83; this Journal, 1890, 275). These substances possess, however, no technical importance, but are of interest in indicating the method of formation of a large number of other bodies.

Progress has also been made in the employment of the heavy tar-oils for disinfection, their value in this direction having been known for a long time; among the substances brought out may be mentioned Pearson's creolin (this Journal, 1886, 274), and more lately Lysol (this Journal, 1890, 1136). Benefit, however, will only accrue to the coal-tar industry when such substances as these are sold at prices having some relation to their real value.

Among other branches which have increased in importance may be mentioned the use of creosote oil in lueigen apparatus, phenanthrene and carbazol, both of which find a ready sale in the colour trade.

The value of the process for the synthesis of indigo from phenylglycocine is still undecided, as is the future of the new explosives prepared from the nitrated hydrocarbons. Taken altogether, the outlook of the industry is very promising.

—F. H. L.

PATENT.

Improvements in and connected with Retorts for Distilling Shale or other Oil-yielding Minerals. F. J. Rowan, Glasgow, and H. Armour, East Breich. Eng. Pat. 11,581, July 24, 1890. 8d.

IN order to facilitate the escape of the vapours or gases generated in retorts used for distilling shale, &c., and thus prevent as much as possible the decomposition of the vapours, a pipe, provided with perforations or slits, is introduced centrally into the top of the retort and extended downwards for a suitable distance; this pipe serves to draw off the vapours and is connected above with the ordinary outlet.

Instead of this simple arrangement a much longer perforated pipe passing from the ordinary outlet almost to the bottom of the retort may be employed when it is desired to treat the material in the retort with steam. This pipe is divided by suitable partitions into three distinct portions of about equal length; the upper one serves for drawing off the vapours as before, and the central one as a sort of channel, through which the gases may pass from one part of the retort to another, and thus be brought into contact with different portions of the fuel; the third and lowest portion is used for the distribution of steam through the material, the steam being brought into this portion of the pipe through a narrow pipe which passes down the whole length of the perforated pipe.—F. S. K.

IV.—COLOURING MATTERS AND DYES.

Action of Sunlight on O-quinone Compounds. H. Kling and O. Standke. Ber. 24, 1340-1346.

Two authors have previously shown (Annalen, 249, 137) that phenanthraquinone unites in direct sunlight with aldehydes, forming ethereal salts of dihydroxyphenanthrone, and it was stated that quinone behaves in an analogous manner forming ethereal salts of quinhydrone. The authors now find that when a mixture of quinone and benzaldehyde is exposed to sunlight a mass of dark green crystals of quinhydrone separates out, and the solution on evaporation yields *quinhydrone-dibenzonate*—

which crystallises in deep brown needles with a violet reflex; melts at 116-117°, and dissolves readily in alcohol and ether. It also dissolves in benzene, but is split up into its constituents on dissolution. It melts when placed in boiling water and is gradually decomposed, quinone passing over with the steam; on heating with sulphurous acid it likewise breaks up into quinone and *benzohydroquinone* (dihydroxybenzophenone) $C_6H_4O_2 \cdot C_6H_5(OH)_2$, the latter forms bright yellow crystals melting at 125° and readily soluble in ether, benzene, and alcohol. It also dissolves in alkalis, but is precipitated on boiling the solution. With benzoyl chloride it yields *benzohydroquinone dibenzonate*, $C_6H_4O_2 \cdot C_6H_5(OOC_6H_5)_2$, which crystallises in brilliant white needles, melts at 118°, and dissolves readily in ether and benzene, and with difficulty in alcohol.

Quinone and isovaleraldehyde are similarly converted on exposure to sunlight into quinhydrone and *isovaleroquinhydrone*, $C_6H_4O_2 \cdot C_6H_4(COO_2H_3)(OH)_2$. The latter crystallises from dilute alcohol in large red plates with a green metallic reflex which gradually become dull yellow on exposure to the air. It melts at 103°, and dissolves readily in alcohol, ether, benzene, and glacial acetic acid. With water it behaves like benzohydroquinone; sulphurous acid converts it into hydroquinone and *isovalerohydroquinone*—

which crystallises from dilute alcohol in yellow needles, melts at 115°, forms orange-coloured solutions with the alkalis, and generally resembles benzohydroquinone in appearance and reactions. It combines with quinone, valeroquinhydrone being formed. With benzoic chloride, it yields *valerohydroquinone dibenzonate*—

which crystallises from alcohol in white needles, and melts at 106°. On hydrolysing this compound, valerohydroquinone is re-formed. Quinone is scarcely attacked in the dark by either benzaldehyde or valeraldehyde, only traces of quinhydrone being formed after many months' action.

S. B. A. A.

Isatine Blue. C. Schotten. Ber. 24, 1366-1373.

Dipiperidylisatine, $C_{12}H_{18}NO_2(C_6H_5N)_2$, is prepared by heating an alcoholic solution of isatine (1 mol.) with piperidine (2 mols.) on the water-bath for about an hour. It crystallises from alcohol in flat colourless prisms, dissolves with difficulty in alcohol and ether, and scarcely at all in benzene and chloroform. It may be heated to 100° without decomposition. It is decomposed by mineral acids in the cold and by warm alkalis. It dissolves in glacial acetic acid with decomposition forming a green solution.

Isatine Blue is obtained when dipiperidylisatine is rapidly heated to a temperature between 120° and 190°, a current of air or other gas being passed over it to remove the piperidine evolved. It is best prepared by warming a mixture of dipiperidylisatine with an excess of acetic anhydride for some time to 60° with frequent agitation, and throwing the resulting blue mass into water. The product is a deep blue, almost black faintly glistening powder consisting of minute prismatic crystals which exhibit a marked dichroism. In the formation of isatine blue three molecules of piperidine

are liberated from every two molecules of dipiperidylisatine, but the remaining piperidine also probably undergoes some change. Isatine blue may be heated without change to 160°, but is completely decomposed at 230°. It dissolves in glacial acetic acid and with some difficulty in alcohol and in ether, forming deep indigo-blue solutions; it is insoluble in benzene and in chloroform. It is readily decomposed by mineral acids, but is more stable in alkaline solution; by prolonged boiling with alcoholic potash the blue colour is, however, gradually discharged, a bright cherry-red solution being formed. The acetic acid solution also turns red on prolonged standing or on heating, and yields a fine purple-red colouring matter very soluble in ether. Similar red solutions may be obtained by heating dipiperidylisatine with anhydrous formic acid or with acid chlorides. On distilling isatine blue with alcoholic potash the distillate contains no piperidine, and the residue does not yield isatine on acidification.—S. B. A. A.

Benzidine-ortho-disulphonic Acid. H. Limpricht.

Annalen, 261, 310-338.

Benzidine-o-disulphonic Acid—

is readily obtained by the reduction with caustic soda and zinc dust of *m*-nitrobenzene-sulphonic acid, and subsequent molecular transformation, by the action of hydrochloric acid, of the hydrazobenzene-disulphonic acid so formed; after allowing the acid solution to stand for several days, the separated benzidine-*o*-disulphonic acid is collected on a filter and washed, and is thus obtained pure (see also this Journal, 1890, 51).

Diazoamidodiphenyl-o-disulphonic Acid is produced by mixing a solution of benzidine-*o*-disulphonic acid (10 grms.) in dilute caustic soda (250 cc.) with one of sodium nitrite (2 grms.), and, after adding ice, slowly running in sufficient dilute sulphuric acid to liberate the nitrous acid. The solution becomes coloured red, provided the temperature remains at 0°, but if it is allowed to rise, the solution takes a yellow colour and then contains tetrazodiphenyldisulphonic acid. After standing several days in the cold, orange or red crystals of the diazo-compound, intermixed with somewhat variable amounts of unchanged benzidine-*o*-disulphonic acid and tetrazodiphenyl-*o*-disulphonic acid, deposit. From this mixture the benzidine-*o*-disulphonic acid may be separated by washing with cold water. Heated with absolute alcohol under a pressure of 400 mm., *p*-diazoamidodiphenyl-*o*-disulphonic acid yields a compound insoluble in alcohol, which was not closely examined.

Hydrazoamidodiphenyl-o-disulphonic Acid is obtained by heating the above diazo-compound with water. Its barium salt forms a soft, pale yellow mass, which, on standing over sulphuric acid, sometimes becomes crystalline; it contains 7 or 8 mols. of water of crystallisation, is easily soluble in water and alcohol (96 per cent.), and is precipitated by ether from its solution in the latter.

Hydrazoamidodiphenyl-o-disulphonic Acid is prepared by the action of an acidulated solution of stannous chloride on the diazo-compound, and is purified in the usual manner; its barium salt crystallises with 4 H₂O.

Amidodiphenyl-o-disulphonic Acid—

is obtained on boiling the aqueous solution of the last described compound with copper sulphate; its barium salt contains 4 H₂O.

Tetrazodiphenyl-o-disulphonic Acid—

is prepared by the action of nitrous acid (from 10.2 grms. of NaNO₂) on benzidine-*o*-disulphonic acid (25 grms.) in the

way described for the diazo-compound, crystallises with probably 2 mols. of water, is stable only at low temperatures, and on boiling with water is converted into *dihydroxydiphenyl-o-disulphonic acid*; on reduction with acidified stannous chloride, *dihydrazindiphenyl-o-disulphonic acid* is produced. The latter crystallises, with 2 H₂O, in rhombic prism, and is very unstable; its barium salt is remarkable for its stability on heating and for the tenacity with which it retains on drying 1 mol. of the 3 mols. of water it contains, the last mol. of water being removed only after prolonged drying at 180°, and the salt undergoing little decomposition at this temperature.

Diphenyl-o-disulphonic Acid is produced on boiling the last-described compound with copper sulphate solution, or by treating the same, in presence of alcohol, with copper powder; it forms an uncrystallisable syrup; its barium salt crystallises in prisms, containing 6.5 H₂O.

o-Diphenol is obtained on fusing diphenyl-o-disulphonic acid with a mixture of potash and soda, and extracting with ether the acidified solution of the fused mass. It was purified by treating its solution in benzene with light petroleum, which precipitates resinous matters. After removal of these solvents by distillation and allowing the residue to stand over sulphuric acid, it was obtained in large, colourless prisms, melting at 99°, and possessing a faint, phenol-like smell. This compound is identical with that obtained by Hodgkinson and Matthews (Ber. 16, 1103) by fusing fluorene with potassium hydrate.

Tetranitrodiphenyl-o-disulphonic Acid—

is formed by the action of nitric acid on dihydroxydiphenyl-o-disulphonic acid; its potassium salt forms pale-yellow crystals. The author did not succeed in preparing the acid potassium salt of this compound.—E. B.

Chloranil. C. Graebe. *Annalen*, 263, 16—31.

HITHERTO chloranil has almost invariably been prepared from phenol, both in the laboratory and on the large scale. In place of phenol the author recommends the use of *p*-phenylenediamine or its hydrochloride, both of which are now commercial products. Chloranil has already been obtained from this compound by Krause (Ber. 12, 52) by passing chlorine into its acetic acid solution, but the following method is recommended by the author for preparing it either on the large or small scale: 100 grms. of *p*-phenylenediamine hydrochloride are mixed with 250 cc. of water and 800 cc. of crude hydrochloric acid in a cooled vessel of such size that it is only filled to one-third of its capacity, and 250 grms. of potassium chlorate crystals gradually added in such a manner that the temperature is at the beginning not higher than 35°–40°, and later not higher than 20°–30°, which requires about a day.

After standing over night the whole is gradually warmed to 100° in a water-bath, heated till all the chlorate is decomposed, filtered, and well washed with hot water. 115 grms. of crude chloranil are thus obtained, and are purified by warming the substance, which need not be quite dry, with 350–400 cc. of crude hydrochloric acid for two hours on the water-bath; the trichloroquinone is thus converted into chloranil, trichloroquinol, and tetrachloroquinol, whilst the chloranil is scarcely affected. The trichloroquinol may be first extracted with water, which also takes up a little tetrachloroquinol, or the whole may be directly oxidised preferably with a little potassium bichromate. If recrystallised chloranil is required, the best solvent is toluene purified with sulphuric acid, or for small quantities acetic acid.

Chloranil after repeated crystallisation from toluene melts, if heated in a sealed tube at 290°, but varieties melting at 280° give good numbers on analysis and may be regarded as pure.

The crude chloranil may also be purified by means of nitric acid, which removes the trichloroquinone, but simul-

taneously acts to some extent on the chloranil, and is therefore not so suitable as hydrochloric acid. If it be required also to isolate the trichloroquinone, the mixed compounds may be moistened with alcohol, mixed with 10 times the quantity of water and a strong current of sulphurous anhydride passed through the liquid for 10 to 15 minutes at the ordinary temperature. The residue is extracted with alcohol, which removes the remaining trichloroquinol and the small quantity of hydrochloranil formed. To convert either chloranil or trichloroquinone by themselves into the corresponding quinols, it is best to employ amorphous phosphorus and hydriodic acid.

To convert chloranil into chloranilic acid, 10 grms. of the former, which may be taken in the crude or pure condition, are well moistened with alcohol, added to a solution of 9 grms. of caustic soda in 220 cc. of water warmed to 80°, allowed to remain for two hours, and 20 grms. of common salt then added. The crystals which have separated after some hours are washed with a 10 per cent. salt solution till almost colourless. The residual sodium salt is washed pure with a small quantity of water to remove sodium chloride, and then recrystallised from a large quantity of the hot liquid. The chloranilic acid obtained thus should be washed first with dilute hydrochloric acid and then with water. If crude chloranil be used 42–44 grms. of chloranilic acid will be obtained for every 100 grms. of *p*-phenylenediamine hydrochloride employed, whilst if the chloranil be purified with hydrochloric acid, 46–50 grms. are obtained.

Chloranilic acid crystallises with 2 mols. H₂O, which it loses slowly over sulphuric acid in a vacuum, and quickly at 115°. Water dissolves 0.19 parts of the anhydrous substance at 13.5° and 1.41 parts at 99°. The solubility of the potassium and sodium salts has also been determined: 100 parts of water dissolve 1.77 parts of the former at 20°, and 9.25 parts at 98.6°, and 1.06 parts of the latter at 21°, and 6.19 parts at 99°.

To prepare hexachlorobenzene from chloranil it is best to employ a mixture of phosphorus trichloride and pentachloride in equal molecular proportions, and heat them with chloranil at 190°–200°. The yield is almost quantitative.

With regard to the constitution of quinone, the author whilst regarding the diketone formula as, on the whole, the more probable, does not believe that our knowledge is yet sufficient to decide definitely between this and the peroxide formula.—H. G. C.

Bromanil. C. Graebe and L. Weltrier. *Annalen*, 263, 31–38.

BROMANIL, like chloranil (see preceding abstract), may be readily obtained from *p*-phenylene diamine; 10 grms. of the latter are dissolved in 40 cc. of acetic acid, gradually poured into 40 cc. of bromine in a beaker cooled by water. After remaining over night, the mixture is warmed in a hot water bath, mixed with water, the dried precipitate purified by excessive warming with 40 cc. of ordinary and of fuming nitric acid. The bromanil thus obtained is almost pure and may be converted into bromanilic acid and *p*-hexabromobenzene by the methods used for the corresponding chlorine compounds.—H. G. C.

m-Nitro-p-amidophenol and its Derivatives. H. Hähle. *J. prakt. Chem.* 43, 62–75.

DIACETYL-*p*-amidophenol is conveniently prepared by treating *p*-amidophenol, rapidly dried in a current of hydrogen at 130°–140°, with twice its weight of acetic anhydride. A lively reaction takes place on the application of heat and the reaction is completed by heating half an hour in a reflux apparatus. After removal of the greater part of the solution by distillation, the residue is crystallised from water. The compound crystallises in large plates melting at 150°. By the action in the cold of fuming nitric acid (1½ parts) on this compound (1 part), *m*-nitrodiacetyl-*p*-amidophenol is obtained. The latter crystallises from dilute alcohol in splendid, pale-yellow prisms, melts at

146–147°, and boils, with considerable decomposition, at 260°; it is sparingly soluble in water, moderately soluble in acetic acid, alcohol, and ether.

m-Nitro-*p*-amidophenol is produced by the action of alkalis, avoiding excess, or acids, on *m*-nitro-acetyl-*p*-amidophenol. Crystallised from alcohol and finally from ether, it appears as dark-red prisms with a green reflex, melting at 118°, and decomposing at a higher temperature; crystallised from water, it contains 1 mol. of water of crystallisation; its aqueous solution has an orange-red colour, which is changed to pale yellow by acids, and to deep-purple by alkalis; its hydrochloride and sulphate are decomposed by water; its tetramethylammonium compound, prepared by the action of tetramethylammonium hydroxide in aqueous solution, yields, on heating, a small quantity of *nitro-p*-anisidine. This crystallises in dark-red prisms or plates, melting at 123°, is soluble in water, alcohol, and ether, less so in benzene, and volatilises with steam; its acetyl compound melts at 115°.

m-Nitro-*p*-diazophenol Chloride is prepared by suspending *nitro-p*-amidophenol hydrochloride in alcohol, to which a little hydrochloric acid has been added, and treating it, whilst well cooled, with a current of nitrogen trioxide. The greater part of the diazo-compound separates out; the remainder may be precipitated by the addition of ether. It is thus obtained in the form of pale-yellow, microscopic prisms, which exhibit the characteristic properties of diazo-compounds, decomposing violently at 126–129°. Azo-derivatives are readily obtainable from it by interaction with dimethylaniline and resorcinol, an alcoholic solution of the former giving a chocolate-coloured compound, which dissolves in hydrochloric acid with a rich, red colour, and an alkaline solution of the latter yielding a red-brown solution which gives a precipitate of the same colour on the addition of acid. On heating a solution of *m*-nitro-*p*-diazophenol chloride in absolute alcohol under a pressure of 750–800 mm., *m*-nitrophenol is obtained; the production of this compound determines the constitution of the above-described *nitro-p*-amidophenol. Unsuccessful attempts were made to prepare nitroquinol by heating *m*-nitro-*p*-diazophenol with acids and by heating the perbromide of the same compound with alcohol, *m*-nitrophenol being in each case obtained. It was also found impossible to prepare a nitroquinone-chlorimide by the action of calcium hypochlorite on *nitro-p*-amidophenol, such a compound being probably highly unstable owing to the presence of the nitro-group in its molecule.

m-*p*-Diamidophenol is obtained by reducing *m*-nitro-*p*-amidophenol. It melts with decomposition at 167–168°; aqueous solution it becomes oxidised, on exposure to air or by treatment with ferric chloride, with formation of a brown dyestuff, probably a substituted phenazine, which dissolves in hydrochloric acid with a crimson colour; the triacetyl derivative of *m*-*p*-diamidophenol melts at 135–136°.

m-*p*-Diamidocyanisol Hydrochloride, obtained by reducing *m*-nitro-*p*-anisidine with tin and hydrochloric acid, is very prone to oxidise, yielding a red colouring matter; it crystallises in colourless lustrous leaflets, and dissolves in water with a brown colour.

m-Nitro-*p*-indophenol, prepared by the action of hydriodic acid in the cold on *m*-nitro-*p*-diazophenol, crystallises in yellow needles, melting at 140°; it is freely soluble in cold water, more easily so in hot, and does not volatilise with steam; on fusion with potash it yields hydroxyquinol; on boiling with alcoholic potash *m*-nitrophenol was obtained instead of the expected nitroquinol.

m-Nitro-*p*-indophenol is produced by the action of ethyl iodide on the salt or compound of *m*-nitro-*p*-indophenol. The reaction is so violent that it is necessary to moderate it by the addition of alcohol or ether to the mixture. The compound obtained crystallises in pale yellow, microscopic needles, melting at 61.5°, and boiling, with slight decomposition, at 320°; it is insoluble in cold, and very sparingly soluble in hot water, but easily soluble in alcohol and ether, and is volatile with steam.—E. B.

Nitro-Derivatives of Dimethylortho-anisidine. E. Grimaux and L. Lefèvre. *Compt. Rend.* **112**, 727–730.

In a previous communication one of the authors has drawn attention to the difference in behaviour between ortho- and meta-dimethylanisidine as regards the formation of colouring matters; they have now studied some of the nitro-derivatives of the ortho-compound.

The mononitro-derivative $\text{N}(\text{CH}_3)_2 \cdot \text{C}_6\text{H}_3(\text{NO}_2) \cdot \text{OCH}_3$ [$\text{N}(\text{CH}_3)_2 : \text{NO}_2 : \text{OCH}_3 = 1 : 4 : 6$] is obtained, together with a compound melting at 170°, which seems to be a dinitro-derivative, when dimethylortho-anisidine is gradually added to ice-cold, fuming nitric acid; it is, however, most easily prepared by dissolving the base (1 part) in dilute (1:10) sulphuric acid (2 parts), and gradually adding a solution of sodium nitrite (3.2 parts) in water (60 parts); it is purified by recrystallisation from alcohol, from which it separates in slender yellow needles, melting at 99°. On reduction with zinc and hydrochloric acid it gives a colourless crystalline base, which melts at 83°, and turns reddish on exposure to the air.

The trinitro-derivative—

is formed when dimethylortho-anisidine is warmed with concentrated nitric acid until oxides of nitrogen begin to be evolved. It crystallises from boiling alcohol in colourless prisms, melting at 135°, and when boiled with 10 per cent. potash it is converted into dinitroguaiacol (melting point 121–122°); this behaviour shows that the trinitro-compound has the constitution—

Trinitromethylortho-anisidine—

is obtained when dimethylortho-anisidine, or either of the nitro-compounds described above, is boiled with concentrated nitric acid (15–20 parts) until the evolution of oxides of nitrogen is at an end. It crystallises from alcohol in almost colourless plates, melts at 118°–119°, and is decomposed by boiling 10 per cent. potash, yielding dinitroguaiacol (melting point 121°–122°).—F. S. K.

Some New Compounds of Aniline with certain Metallic Sulphites. G. Denigès. *Compt. Rend.* **112**, 802–805.

The author has discovered a whole series of new bodies formed by the union of aniline and its homologues with various metallic sulphites, and also with the salts of other polybasic acids. In the present paper only the compounds of aniline with certain metallic sulphites are considered. They may be represented by the general formula—

and are readily obtained by mixing an aqueous solution of aniline with solutions of the respective metallic bisulphites. Or aniline dissolved in water may be added to a solution containing sodium bisulphite and a soluble salt of the metal whose aniline compound is required. Another way is to saturate a solution of the metal with sulphurous acid and then add aniline. The bodies thus obtained all form clear, lamellated, hexagonal crystals, almost insoluble in water and other neutral solvents. Aldehyde and acetone appear to dissolve certain of them with decomposition.

Cuprous Aniline Bisulphite. $(\text{SO}_3)_2\text{Cu}_2\text{H}_2(\text{NH}_2\text{C}_6\text{H}_5)_2$, forms silky, yellowish white, hexagonal crystals, which are not affected by air or light when quite dry. The salt is soluble in ammonia and by hydrochloric acid.

Cadmium Aniline Bisulphite. $(\text{SO}_3)_2\text{Cd} \cdot \text{H}_2(\text{NH}_2\text{C}_6\text{H}_5)_2$, and *zinc aniline bisulphite*, $(\text{SO}_3)_2\text{Zn} \cdot \text{H}_2(\text{NH}_2\text{C}_6\text{H}_5)_2$, resemble each other closely. Both form white hexagonal plates.

Manganese Aniline Bisulphite. $(\text{SO}_3)_2\text{Mn} \cdot \text{H}_2(\text{NH}_2\text{C}_6\text{H}_5)_2$, crystallises in hexagonal plates of a very faint pinkish colour.

Cobalt aniline bisulphite. $(\text{SO}_3)_2\text{Co} \cdot \text{H}_2(\text{NH}_2\text{C}_6\text{H}_5)_2$, is of a beautiful rose colour.

Ferrous Aniline Bisulphite, $(\text{SO}_3)_2\text{FeH}_2(\text{NH}_2\text{C}_6\text{H}_5)_2$, resembles ferrous oxalate in appearance.

Nickel Aniline Bisulphite, $(\text{SO}_3)_2\text{NiH}_2(\text{NH}_2\text{C}_6\text{H}_5)_2$, separates in greenish-yellow crystalline crusts.

Mercuric Aniline Bisulphite—

differs from the preceding salts in containing only one molecule of aniline. It forms white crystalline plates.—H. T. P.

The Simultaneous Action of Air and Light on a Number of Organic Compounds. A. Bidet. Bull. Soc. Chim. 1891, 5, 13–20.

DETAILS of a number of experiments are given, which go to show that many aromatic compounds which become coloured, or which darken in colour when exposed to the light, remain unalterable when prepared in a state of special purity. Amongst the bodies examined are:—Nitrobenzene, nitrotoluene, phenol, aniline and its salts, resorcinol, benzyl chloride, benzaldehyde, cinnamic acid, nitro-cinnamic acid, naphthol, naphthylamine and its salts and quinoline and its salts. The author found that when benzene or toluene, carefully freed from thiophene and its homologues by treatment with sulphuric acid, was used in the preparation of any of the above bodies, these latter could be exposed to light for a long period without undergoing any change at all, whereas the ordinary commercial products not treated thus darkened rapidly. Another method of purification adopted with phenol, resorcinol, and naphthylamine was to sublime the product very carefully when the substance or substances giving rise to the colouration are left behind. These specially purified bodies were characterised by a more agreeable and less marked smell than is usually associated with them. The addition of nitrothiophen to the purified nitrobenzene caused the latter to darken as usual on exposure. Nitrothiophen itself does not darken in sunlight, in absence of air, but very readily in its presence. By very careful and repeated sublimation of nitrothiophen, the author was able to separate it into a crystalline sublimate, which was not affected at all by exposure to air and light, and a liquid residue which is darkened at once when exposed. No details concerning this latter body are given.—C. A. K.

Alkyl-Hydroxy-derivatives of Dimethylaniline.

E. Grimaux. Bull. Soc. Chim. 1891, 5, 646–649.

ALREADY abstracted from Compt. Rend. 112, 290–292; this Journal, 1891, 459.

Notes on the Azo-derivatives of β -Naphthylamine.

R. Meldola and F. Hughes. J. Chem. Soc. (Trans.) 1891, 372–383.

THIS is an extension of the work published by Meldola in conjunction with East (this Journal, 1888, 617) and Morgan (J. Chem. Soc. Trans. 1889, 114 and 603).

Orthonitrobenzene-azo- β -Naphthylamine has been prepared by diazotising orthonitroaniline and adding the product to a cold dilute solution of β -naphthylamine hydrochloride. It forms lustrous bronzy scales, melting at 198° , is soluble in alcohol and benzene, more readily in boiling glacial acetic acid, forming orange-red solutions. In its general appearance it bears a striking resemblance to the isomeride from paranitraniline (J. Chem. Soc. Trans. 1883, 430), whilst the colour of the meta-isomeride (J. Chem. Soc. Trans. 1884, 116) forms a marked contrast to the ortho- and para-compounds. When sodium nitrite is added to a solution of orthonitrobenzene-azo- β -naphthylamine in glacial acetic acid at 70° , the solution left to cool, and then precipitated with water orthonitrobenzene-azo- β -naphthol is obtained, crystallising in orange needles, whilst the meta- and para-nitro-compounds under the same conditions have been shown to yield azonaphthyl-acetates (this Journal, 1888, 617). Orthonitrobenzene-azo- β -naphthol crystallises in orange-red

needles, melting at 209° – 210° , and like other azo-derivatives of β -naphthol is devoid of phenolic character. Ortho-nitrobenzene-azo- β -naphthyl acetate is, however, formed when sodium nitrite is added to a cold saturated solution of the β -naphthylamine azo-compound in glacial acetic acid.

Acetyl-derivatives of the three isomeric nitrobenzene-azo- β -naphthylamines have been prepared; that from the para-compound crystallises in brick-red needles, melting at 227° – 228° ; the acetyl-derivative of the meta-compound forms bright orange needles, melting at 192° , and the corresponding ortho-derivative crystallises in orange-brown needles, melting at 154° .

The Pseudazimides—

are prepared from the nitrobenzene-azo- β -naphthylamines by oxidation with chromic acid in a glacial acetic acid solution. The para compound forms flat, transparent, whitish needles melting at 236° , and the meta-derivative opaque, whitish needles, melting at 223° – 224° ; the ortho-derivative has not been obtained pure.

Action of Nitric Acid on Azo- β -Naphthylamine Derivatives.—Substances are obtained which are more or less explosive and apparently uncrystallisable; their nature is being further investigated.

Action of Aldehydes on the Azo-Derivatives of β -Naphthylamine.—This reaction gives rise to the formation of triazines (see also Goldschmidt and Rosell, this Journal, 1890, 494).

The action of halogens on the azo-derivatives of β -naphthylamine is also being investigated.—A. K. M.

The Action of Nitric Acid on Naphthol Derivatives as Indicative of the manner in which Nitration is effected in the case of Benzenoid Compounds generally. The formation of Nitro-keto-compounds. H. E. Armstrong and E. C. Rossiter. Proc. Chem. Soc. 1891 [98], 89–91.

WHEN warmed with nitric acid, the chloro- and bromo-derivatives of β -naphthol are converted into derivatives of β -naphthaquinone, but, as the authors have pointed out in their previous notice, the formation of these products is preceded by that of an unstable intermediate compound. When these intermediate compounds are carefully heated, they are converted into bromo-derivatives of β -naphthaquinone, and in preparing these latter it is desirable to separate the intermediate compound from the excess of nitric acid, and to decompose it by carefully heating it with acetic acid, except in the case of tetrabromo- β -naphthol; tribromo- β -naphthaquinone is so readily formed from this compound, and is so difficultly soluble and well characterised, that small quantities of tetrabromo- β -naphthol may be detected in presence of the di- and tri-bromo-derivatives by simply heating the mixture with acetic acid and nitric acid. Thus, if nitric acid be added to dibromo- β -naphthol, suspended in acetic acid, a clear solution is obtained which, after a short time, deposits a crystalline substance; if quickly separated by filtration, this product is almost colourless, but it decomposes when kept, becoming yellow. It was conceivable, judging from the manner in which it was produced, that the compound was a nitrate, formed by the simple displacement of the hydroxylic hydrogen by NO_2 , and the results of analysis were in accord with this view; but such a nitrate should be reconvertible into the parent substance by treatment with alkali, whereas actually it affords, as chief product, *bromonitronaphthol*. Bromo- β -naphthol, in like manner, eventually yields α_1 -nitro- β -naphthol, and the tri- and tetra-bromo-derivatives afford di- and tri-bromonitro- β -naphthol; the bromine atom displaced by NO_2 by this method of treatment, there can be little doubt, is invariably that in the α_1 -position.

The authors are of opinion that the intermediate compounds in question are nitro bromo-keto-derivatives corresponding to the di-chloro-keto-compounds of Zincke, and that their formation affords evidence that the elements

of nitro acid first become added to the bromonaphthol, thus—

The theory that the formation of such addition compounds precedes that of nitro-compounds generally appears to afford a satisfactory explanation of a large number of well-known facts which hitherto have remained unexplained. The non production of nitro-compounds from paraffins and their derivatives, except in a certain very limited number of special cases, appears as the natural consequence of the inability of paraffins to form addition compounds. The theory affords a simple explanation of the formation of nitro-derivatives of *phenols* on nitrating hydrocarbons, to which Nolting has drawn special attention in the case of toluene and orthoxylylene (Ber. 1885, 2670; 1888, 3158), for if the addition compound lose HNO_2 instead of H_2OH a phenol would result; thus—

An agent that would favour the separation of the elements of water from the addition compound would increase the production of the nitro-compound and diminish that of the phenol; and, as a matter of fact, it is known that when a mixture of nitric and sulphuric acids is used there is less of the phenol derivative produced than when nitric acid alone is employed. A compound such as the addition compound of benzene with nitric acid above represented would obviously be unstable and prone to undergo oxidation; hence it is not difficult to understand that so large an amount of nitrous fume should be produced even on nitrating benzene. The reduction in the amount of such fume, and the improvement of the yield of nitro-derivative effected by adding sulphuric acid, is doubtless attributable to the action already referred to of the acid in promoting the separation of the elements of water; sulphuric acid must be supposed, in fact, in such cases to act not merely as a dehydrating agent in maintaining the nitric acid concentrated, but to exert a specific influence on the course of change. Lastly, the resinous matters often formed in large amount on nitrating many phenols are, doubtless, products of the interaction of several molecules of the addition compounds, or of the keto compounds formed from them in the first instance.

The non production of resinous matters when sulpho-acids are treated with nitric acid so as to form the corresponding nitro-compounds by displacement of the SO_3H group by NO_2 , a modification which often makes it possible to prepare nitro-compounds not obtainable by the direct action of nitric acid, is also explained by the authors' theory; the addition compound formed in such a case would very readily break up into sulphuric acid and the nitro-derivative, thus—

A New Method of Preparing Nitro-Derivatives and the Use of Nitrogen Dioxide as a Nitrating Agent.
H. E. Armstrong and E. C. Rossiter. Proc. Chem. Soc. 1891 [98], 91—92.

REFERENCE has been made in the foregoing note to the production from the compounds formed by the addition of the elements of nitric acid to the bromo-derivative of beta-naphthol of nitro-derivatives of the naphthol on treatment with alkali, a bromine atom becoming displaced by NO_2 . As in this interaction a bromine atom is removed and an atom of hydrogen is added to the CO group, such a method of treatment obviously is scarcely that best calculated to effect the formation of the nitro-derivative, and, as a matter of fact, the nitro-derivative is not the only product. On treating the addition compound, however, with sulphurous acid, a practically theoretical yield of the nitro-naphthol is obtained; this method appears to be of general application.

The authors have been naturally led to study the action of nitrogen dioxide, NO_2 , on unsaturated compounds of various kinds, in the expectation of obtaining addition compounds which by loss of HNO_2 would pass over into nitro-derivatives of the substances treated. They find that such addition compounds are actually obtainable, and that on treatment with alkali and reducing agents they yield nitro-derivatives. Thus beta-naphthol affords as much as 75 per cent. of its weight of nitro-beta-naphthol; alpha-naphthol behaves similarly. In some cases the addition compound is so unstable that it spontaneously decomposes: thus phenol at once yields a mixture of ortho- and para-nitrophenol. The authors propose to study the behaviour of unsaturated compounds generally towards nitric acid and nitrogen dioxide from the point of view indicated in this and the previous note.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

The Theory of Dyeing: Action of Ammonia on Cotton.
L. Vignon. Compt. Rend. 112, 487—489.

THE author has shown that, compared with animal fibres, cotton exerts very little chemical action, as measured by the heat evolved when it is brought into solutions of acids, alkalis, &c. (this Journal, 1890, 771 and 855). The behaviour of cotton towards colouring-matters is consistent with its general chemical inertness. To show that such is the case, the cellulose molecule was modified by treatment in a determinate manner, and the dyeing properties of the resultant compound investigated. This change was effected by heating cotton (1 part) in sealed tubes with ammoniacal calcium chloride (4 parts) or aqueous ammonia (4 parts at 22°) to temperatures between 100° and 200°, for periods varying from a few hours to several days. The chemical properties of the cotton were considerably altered by this treatment, without its physical properties being affected. Samples submitted to analysis, after washing successively with water, dilute acid, and again with water, and then drying at 110°, were found to contain from 1.05 to 2.86 per cent. of nitrogen, the amount varying according to the conditions of treatment with ammonia. When brought into normal sulphuric acid solution, contained in a calorimeter, 0.90 calories were disengaged per 100 grms. of this modified cotton, as against 0.38 calories in the case of bleached, and 0.36 calories in that of unbleached cotton. This mere act of chemical activity of the "ammoniated" cotton coincides with its behaviour in dyeing: samples of it and of ordinary cotton were immersed together in acidulated solutions of various acid dyes, and, on comparing the results, it was found that the "ammoniated" cotton dyed considerably the better, the ordinary cotton being only faintly stained—E. R.

Mordants and the Periodic System. Prud'homme. Bull. Soc. Ind. Mulhouse, 1891, 217—219.

THE author gives some further details regarding the methods of experiment employed by him in studying the relations of the metallic oxide mordants to the periodic system (this Journal, 1891, 362). In ascertaining by means of dye-tests the colouring-effects of the various elements, in addition to the usual methods of fixation by ageing and steaming, use was made of a solution of caustic soda for fixing the mordanting oxides on cotton. For such double mordants as aluminates, silicates, phosphates, arsenates, and antimonates, double decomposition was found to be the most suitable method of deposition on the fibre. Advantage was also taken of the property possessed by a considerable number of metals of forming insoluble tannates, the cotton tissue being first prepared with tannic acid.

Steaming cloth impregnated with dissociable salts of volatile acids gives excellent results; the mordanting salts must, obviously, contain the same acid, for example, acetic acid. The presence of ammonium and sodium acetates, necessary with certain salts, may modify the results obtained. Olefine, also, sometimes considerably affects the shades; redder shades are obtained, for instance, with Alizarin-blue and Mg, Zn, Cd, Ca, Sr, and Ba, on cloth prepared with olefine than on unprepared cloth. In this connexion, the author some time ago (Bull. Soc. Ind. Mulhouse, 1879, 393) drew attention to a remarkable change of shade caused by the presence of olefine on the cloth, in the case of a colour obtained from a mixture of Gallein, acetate of chrome, and calcium chloride, the shade produced being blue, instead of violet as on unprepared cloth.

In the preparation of lakes, the colour-effects were observed by adding solutions ($\frac{1}{2}$ to $\frac{1}{10}$ normal) of the salts of the metals of a given group to separate portions of a solution of a salt of the metal under investigation, and then adding the calculated amount of an alkaline solution of Alizarin or other phenolic colouring matter. In certain cases the shade of an alkaline solution of a colouring matter is affected by the alkali or alkaline salt employed for solution; thus, a sodium carbonate solution of Alizarin is more purple than a potassium carbonate solution of the same; at the moment of mixing, Alizarin-blue 8 gives a purple-blue solution with sodium carbonate, and a yellow-green one with potassium carbonate. An ammoniacal solution of Alizarin yields with the sulphates of Li, Na, and K, solutions varying in colour from violet to red; other salts of these metals produce the same gradation of colour. The reaction is characteristic of the bases, though slightly different shades are produced by the various salts of a particular base; the chloride, bromide, and iodide of potassium, for example, yield somewhat different shades.

The author finds, on continuing his experiments, that some of the statements made in his previous note are incorrect; thus, in the second and fifth groups of elements the shades yielded respectively by Mg, Zn, and Cd, and by P, As, Sb, and Bi, progress regularly and not irregularly as stated; Zn has a yellowing influence; the members of the fourth group do not, strictly speaking, represent the maximum colouring-effect, but a transition state between sub-groups of three elements which resemble one another in general properties; the members of this group give with Alizarin in general orange shades, Pb yielding the reddest shade of that colour.

In the fourth period V appears to be the central element as regards its colour-effects; it gives with Alizarin an orange, which contrasts well with the dull red yielded by Cr.

Fe, Co, and Ni give with Alizarin a series of purples, of which that from Fe is the bluest, and that from Ni the reddest; this trio of elements may be considered as a link between the fourth and fifth periods.—E. B.

The Formation of Insoluble Azo-Colours on the Fibre by Printing. Sealed note deposited March 2, 1889. A. Feer. Bull. Soc. Ind. Mulhouse, 1891, 220—221.

THE cloth is padded with a solution of 30 grms. of β -naphthol and 30 grms. of caustic soda at 38° B. per litre, with

the optional further addition of sodium carbonate, hydrate, phosphate, acetate, &c., and is dried. It is then printed with a mixture containing per litre one-fifth of the molecular weight in grms. of a diazo-compound, in the form of the chloride, sulphate, or, preferably, thiocyanate of the same, the last-named compound being prepared by double decomposition between the diazo-chloride and potassium thiocyanate. The thiocyanates of the diazo-bases are sparingly soluble and fairly stable. The stannic chloride and zinc chloride double salts with the diazo-chlorides are also more stable than the simple diazo-chlorides.

The colours obtained from α -naphthol, resorcinol, and phenol are not fast to soap. These compounds, however, may with advantage be mixed in small quantity with β -naphthol for the purpose of modifying the shades produced, such modified shades being fast to soap.—E. B.

The Formation of Insoluble Azo Colours on the Fibre by Printing. (Note on the preceding article.) A. Feer. Bull. Soc. Ind. Mulhouse, 1891, 222—228.

THE hydroxyazo-colours, obtained by the combination of diazo-salts with phenol, resorcinol, and α -naphthol, are soluble in caustic alkalis, and are, consequently, removed by soaping from fibres, such as cotton, which have no affinity for them, but are faster when produced on wool or silk. The compounds of diazo-salts with β -naphthol no longer contain hydroxyl-groups, but belong to the class of hydrazone-compounds; they are distinguished by their indifferent behaviour towards reagents, insolubility, and fine shades of colour; moreover, they are well suited for application on the various textile fibres, and especially so on cotton.

There are three methods available for the production by printing of the azo-colours on cotton, namely:—

1. Printing a mixture of a phenol and an amido-salt, on cloth prepared with sodium nitrite.
2. Printing a mixture of amido-salt, phenol, and nitrite, on cloth prepared with tartaric acid.
3. Printing a diazo-salt on cloth which has been prepared with an alkaline solution of a phenol.

The last of these methods alone gives satisfactory results. The first and second methods would be advantageous in the production of resorcinol azo-colours on silk, if the colours obtained from that phenol were faster.

The slight excess of acid over that theoretically required, which has to be used in diazotising the amido-compound must be neutralised by the addition of sodium acetate to the mixture before printing on calico, as otherwise the naphthol on the cloth is partly liberated, and very unsatisfactory results obtained. There is no advantage, however, in adding so much sodium acetate as will entirely convert the diazo-salt into acetate, as has been recently recommended.

In thickening the diazo-solution, starch and natural gums must be used; artificial gums reduce the diazo-compound. The temperature of the colour-mixture must not be allowed to exceed 5°.

The cloth, after being prepared, is dried by hot air, and preserved from the direct rays of the sun; it should be printed the same day as it is prepared. All kinds of patterns should be printed with considerable pressure. The colour is instantly produced on the diazo-mixture coming into contact with the naphthol, and remains unaltered throughout the subsequent operations. The printed pieces are passed into dilute sulphuric acid (5 per cent.), washed, dried, and cleared. The colours produced are very full and bright; they are almost as fast to light as a medium shade of indigo, are unaffected by acids, and withstand soaping at 75°.

Different diazo-mixtures may be printed to produce patterns in several colours, or alizarin colours, which develop well on cloth prepared with β -naphthol, may be associated with the diazo-colours for the same purpose.

Sodium β -naphtholate acts as a resist for aniline black.

Reserve patterns under the diazo-colours may be produced in several ways; the prepared calico may, for example, be printed with a thickened solution of an acid to liberate the naphthol; or the naphthol may be converted into a body incapable of combining with a diazo-salt, by

printing on it thickened solutions of nitrous acids, sulphites, or stannous chloride. The last compound is preferred in practice: a mixture containing up to 1,200 grms. of stannous chloride per litre is printed, the cloth dried, padded with the diazo-salt, and then passed through dilute acid, rinsed, soaped, dried, and cleared.

With wool the best results are obtained when the cloth is chlorured and prepared with free β -naphthol. The latter is effected by padding it with a solution of β -naphthol (35 grms.) in dilute caustic soda (35 grms. at 38° B. per litre) and, without drying, passing through a bath of ammonium chloride (50 grms. per litre), then rinsing and drying in a stentering machine. The printing is the same as for cotton.

Silk in its behaviour is intermediate between wool and cotton. Good colours are obtained on it both when prepared with free β -naphthol and with sodium β -naphtholate, provided that the diazo-mixture contains little or no excess of acid. (See also this Journal, 1890, 1125 and 1126; and preceding abstract.)—E. B.

Method of Determining Indigotine for Commercial Purposes. F. A. Owen. J. Amer. Chem. Soc. 1891, 13, 32—33.

See under XXIII., page 729.

PATENTS.

An Improved Process for Dyeing Wool, and Apparatus for Use in the same. P. Cavaillès, Paris, France. Eng. Pat. 7202, May 8, 1890. 8d.

The inventor makes four claims: first, for a concentrated indigo vat, which is prepared by adding milk of lime (20 litres) to indigo (10 kilos.) previously moistened with hot water (10 litres at 60°), and then treating the mixture with the sodium "hydrosulphite" obtained from the interaction of sodium bisulphite (25 kilos. at 30° B.) and zinc powder (2 to 3 kilos.); sufficient of this concentrated vat to be added to the dye-vat to obtain the desired shade of blue in one "dip." The second claim is for the "optional adjunction to the dye-vats of a squeezing apparatus," of which a drawing is given with the original specification. The third claim relates to the "employment of this vat for dyeing wool, cotton, and other vegetable fibres, either hot or cold," and the fourth deals with methods of "brightening" the colour on the dyed fibre by the use of "acids or acid-salts which do not attack either the wool or the colour," "of sulphides or chlorides, oxygenated water, barium dioxide, and in general of any oxidising agents in suitable proportions."—E. B.

Improvements in Machinery for Dyeing, Scouring, and Drying Hanks. E. and D. Sykes, Huddersfield. Eng. Pat. 8134, May 24, 1890. 8d.

Two discs are fixed parallel to each other on a horizontal shaft, and mounted to rotate in a dye-vessel. The discs carry inner and outer horizontal cross-bars, arranged in pairs. A slow revolving motion is imparted to either the outer or inner sets of cross-bars by suitable gearing attached to the same and to the shaft which carries the discs. The hanks to be dyed, &c., are placed on the cross-bars and in this way caused to continuously move their position on the bars whilst being carried round by the discs. Arrangements are made for the slackening of the hanks whilst in the dye, or other liquor, as it is found that the yarn receives the solutions better when not in a state of tension. Further, to obviate the lying of the loose fibres in one direction by the passage of the yarn through the liquors, the motion of the revolving discs is, at intervals, reversed by self-acting mechanism. The mechanical details are fully explained in the original specification by the aid of two sheets of drawings.—E. B.

Improvements in Colouring, Sizing, and otherwise Treating Paper, and in Apparatus therefor; also applicable for Filling and Treating Woven Fabrics. J. M. Campbell, Disley. Eng. Pat. 8183, May 27, 1890. 8d.

THE paper *a* (see Fig.) to be coloured, &c., is wound upon a roller *b*, supported in bearings on standards *c*, from which it passes over a guide roller *d* to the main drum or roller *e*. The roller *e* is driven positively and itself drives, preferably by means of expanding pulleys or change wheels, the axle of the upper sieve roller *f*. The sieve cloth *g* passes from the upper roller *f*, which may be fixed, but is preferably adjustable, to two rollers *h*, supported by the colour-box *i*, which also carries the colour-furnishing roller *j* and is adjustable to the main drum *e*. The sieve cloth and the drum *e* are driven preferably in the same direction.

By moving the colour-box and the lower sieve rollers nearer to, or further from, the drum *e*, a greater or smaller surface of contact between the paper to be coloured, &c., and the sieve cloth is produced. The colour, &c., is fed on to the sieve cloth in the usual manner, and the surplus colour, &c., preferably removed from the same by a "doctor" or brush applied at the point *x*.

In colouring hard or smooth paper, the frame with the colour-box, &c., or the upper sieve roller *f*, is brought nearer to the drum *e*, in order to give a large surface of contact, and increase the friction between the sieve cloth and the paper; for soft or rough paper, the colour-box, &c., is moved away from the drum, to reduce the surface of contact and increase the speed of the sieve cloth in order to diminish the friction on the paper.

The apparatus and method are also applicable for "backing," filling, and otherwise treating woven fabrics.

—E. B.

Improvements in Apparatus for Washing, Dyeing, and Treating Textile Materials and Goods. E. Sutcliffe and G. E. Sutcliffe, Halifax. Eng. Pat. 8270, May 28, 1890. 8d.

THIS invention is to some extent an improvement on Eng. Pats. 10,933 and 14,971 of 1886 and 4509 of 1887. According to the former inventions the materials (wool tops, raw cotton, &c.) to be dyed, &c. were coiled or massed around a hollow, perforated pipe, which could be revolved while the dye or other liquor was forced through it and the surrounding materials. The objects of the present invention, it is stated, are to increase the productive capacity of the apparatus and to bring its action more under the control of the operator, especially when the apparatus is used for dyeing. A number of perforated pipes or conduits are arranged to radiate from a central hollow shaft or barrel into which the liquor is forced or discharged under pressure. The hollow shaft is mounted so that it can be slowly revolved whilst the liquor is being discharged through the goods. A detailed description of the mechanism employed is given in the original specification with the aid of drawings.—E. B.

Improvements in the Production of Azo-Colours upon Fibres. B. Wilcox, London. From the "Farbenfabriken vormals F. Bayer und Co.," Elberfeld, Germany. Eng. Pat. 8530, June 2, 1890. 6d.

COTTON is dyed shades ranging from blue or violet to black by first dyeing it with the colouring matter obtained by the combination of 1 mol. of the tetrazo derivative of benzidine, tolidine, dianisidine, or diamidostilbene with 2 mols. of amidonaphthol sulphonic acid G, or with 1 mol. of this compound and one of a phenol or aromatic amine, and then diazotising on the fibre this amido or diamido dyestuff, and combining the resultant body with 1 or 2 mols. of a phenol or amido compound; thus, cotton which has been dyed with the colouring matter produced by the combination of 2 mols. of amidonaphthol sulphonic acid G with 1 mol. of tetrazodiphenyl, after being treated in a cold dilute solution of nitrous acid, gives the following shades when worked in baths containing the substances mentioned:—

Developing Substance.	Shade Produced.
Phenol.....	Blue-black.
Resorcinol.....	Green-black.
Salicylic acid.....	Blue-black.
α -Naphthol.....	Violet-black.
β -Naphthol.....	Blue-black.
m -Phenylenediamine.....	Green-black.
α -Naphthylamine.....	Black.
β -Naphthylamine.....	Reddish-black.

The various naphthol- and naphthylamine-sulphonic acids and the dihydroxynaphthalenes and their sulphonic acids yield black or very intense shades. The combination of the phenols and amido-phenols is effected in an alkaline solution, that of the amines in an acetic acid solution. Some of the colouring matters so produced on the fibre which contain amido groups, can be again diazotised and combined with phenols, amines, &c.—E. B.

Improvements in the Treatment of Fabrics Printed or Dyed with several Colours. W. L. Wise, London. From "Favre and Braun," Mulhouse, Germany. Eng. Pat. 8809, June 7, 1890. 6d.

INSOLUBLE tannates, such as those of antimony, zinc, lead, and tin, are added to soap-baths in the treatment of printed calicoes for the purpose of precipitating from solution the basic dyes which become to some extent detached from the cloth in this operation. The brightness and purity of alizarin and similar colours, &c. are in this way preserved, and it is possible to work for a long time without renewing the bath; thus, a bath prepared with 5 kilos. of soap and 1 to 2½ kilos. of moist tannate of antimony, per cubic metre of water, can be used "for weeks." (See also this Journal, 1891, 361.) —E. B.

Improvements in Machinery for Dyeing Hanks of Silk and other Yarn. A. H. Wardle, Leek. Eng. Pat. 11,100, July 16, 1890. 11d.

THE object of this invention is to provide mechanism for simultaneously dyeing a number of small parcels of silk or other yarn as many different colours or shades of colour, so as to economise labour in the execution of small orders for dyeing.

Six or more small dye-baths are fitted up in a line alongside one another. The hanks to be dyed are suspended from reels, which are fixed above the surface of the dye-liquors, and caused to rotate on their axes, and, at the same time, around given points, the regular dyeing of every part of the yarn being thus ensured. No adequate description of the mechanical details of this invention can be given without reference to the drawings which accompany the original specification.—E. B.

Improvements in Machinery and Arrangements to be used in connexion with Apparatus for Bleaching, Dyeing, or Washing Textile Fabrics, Warps, and Yarns. J. T. Reid, C. Edmeston, and A. Edmeston, Salford. Eng. Pat. 11,306, July 19, 1890. 11d.

THE object of this invention is to provide mechanism for rendering automatic the operation of "piling" textile piece-goods, warps, or yarns, which have been passed through bleaching and related apparatus, the invention being more especially applicable to bleaching keirs which operate simultaneously on two or more lengths of fabrics passed continuously through the same, such as the keir patented by Bentz, Edmeston, and Grether (this Journal, 1890, 388). Apart from the four sheets of drawings which accompany the original specification, no proper description of the mechanical arrangements by which this object is effected can be given.—E. B.

Improved Process of Dyeing or Printing in Aniline Black or Analogous Colours. H. Thies, Laaken, and F. Cleff, Raunthal, Germany. Eng. Pat. 2533, February 12, 1891. 4d.

USE is claimed, in the production on the fibre of aniline black or analogous colours, of hydrofluoric acid along with, or instead of, the acids commonly employed in combination with aniline, &c., for this purpose. The advantages attending the use of hydrofluoric acid are: the "acidity" of this acid, which, compared with that of hydrochloric acid, is in the ratio of 100:5; its non liability to decomposition; its property manifested on being liberated and volatilised in the course of the development of the black, of absorbing "much of the heat which interferes with the effect of the increasing energy of the heat of oxidation on the fibre;" the black produced is not affected by "sulphurous acid or by acids generally," and since "it has not the basic properties of ordinary aniline black," it "combines more easily with tar colours;" and, most important of all, the black is produced without diminishing the lustre of silk or the softness of wool, and vegetable fibres "scarcely suffer." As an example of the application of hydrofluoric acid in the black dyeing of mixed fabrics of cotton and silk, the following recipe is given: 55 grms. of hydrofluoric acid (60 per cent) diluted with 200 cc. of water, are mixed with a solution of ammonium and copper chlorides, prepared by acting on 2 grms. of copper carbonate and 1 grms. of ammonium bicarbonate with 25 grms. of hydrochloric acid (30 per cent), then 140 grms. of aniline are added, and, finally, 60 grms. of sodium chlorate dissolved in a little water, and the whole is diluted with water to 1 litre.—E. B.

VII.—ACIDS, ALKALIS, AND SALTS.

Sodium Manganates. G. Rousseau. Compt. Rend. 112, 525—527.

A SERIES of compounds of soda and manganese dioxide are obtained by heating sodium manganate to temperatures varying from 300°—1,300° C. When crystallised from water they have the following compositions. At 300° C. $8 \text{ MnO}_2 \cdot \text{Na}_2\text{O} \cdot 5 \text{ H}_2\text{O}$; at 800° C. $12 \text{ MnO}_2 \cdot \text{Na}_2\text{O} \cdot 4 \text{ H}_2\text{O}$; at 1,000° C. $16 \text{ MnO}_2 \cdot \text{Na}_2\text{O} \cdot 8 \text{ H}_2\text{O}$, and at 1,200°—1,300° the same as at 300° C., and then at a white heat the same as at 800°; the salt going through the same cycle of changes as at the lower temperatures.—A. L. S.

On some Ammonia Compounds of Mercuric Cyanide. R. Varet. Compt. Rend. 112, 535—536.

IF a saturated solution of cuprammonium bromide be added to a solution of mercuric cyanide in ammonia, on standing crystals are deposited, having the composition

$\text{Hg}_2\text{Cl}_2 \cdot \text{CdBr}_2 \cdot 2\text{NH}_3$. If the salt $\text{Hg}_2\text{Cl}_2 \cdot \text{CdBr}_2 \cdot 3\text{H}_2\text{O}$ be added to a warm solution of ammonia until the solution is saturated, crystals are deposited on standing, having the composition $\text{Hg}_2\text{Cl}_2 \cdot \text{CdBr}_2 \cdot 2\text{NH}_3 \cdot 2\text{H}_2\text{O}$.

An ammoniacal solution of cadmium iodide containing an excess of the latter is added to an ammoniacal solution of mercuric cyanide as long as the latter dissolves it. The filtered solution deposits crystals having the composition—

Effect of Haloid Potassium Salts on the Solubility of Potassium Sulphate. C. Blarez. *Compt. Rend.* **112**, 939-942. (See page 717.)

The solubility of potassium sulphate in water practically increases with the temperature, and the quantity dissolved in 100 parts of water, between the limits 0 and 30, may be represented by the formula—

$$Q_t = 8.5 + 0.12 t.$$

The slightest addition of a haloid potassium salt renders some of the sulphate insoluble, the quantity being proportional to the amount of potassium contained in the haloid salt added, as illustrated by the following numbers obtained with potassium bromide:—

	Percent of $\text{KBr} \cdot \text{K}$.	SO_4K_2 dissolved.	$\text{SO}_4\text{K}_2 + \text{K}$
		Per Cent.	
1	0.327	9.43	9.76
2	0.654	9.10	9.75
3	0.980	8.34	9.32
4	1.308	8.11	9.45
6	1.960	7.52	9.48
8	2.616	6.56	9.15
12	3.924	5.62	9.51
		Mean.....	9.49

indicating that—

$$\text{SO}_4\text{K}_2 \text{ dissolved} = \text{constant} - \text{K of the salt added.}$$

In subsequent experiments on the solubility of potassium sulphate in a 6.1 per cent. solution of potassium bromide ($\text{K} = 2.04 \text{ K}$) it was found that between 0 and 30 the solubility varied in the manner represented by the following formula

$$Q_t = 5.5 + 0.1417 t$$

the constant at any temperature would be between these limits—

$$\text{Constant at } t = 7.5 + 0.1417 t$$

which, applied to the second equation, gives—

$$\text{SO}_4\text{K}_2 \text{ dissolved at } t = 7.5 + 0.1417 t - \text{K of the salt added}$$

Numerous experiments have been made with potassium chloride, bromide, and iodide, and the actual numbers obtained agree within experimental error with numbers calculated on the above basis, and prove that the precipitating action of potassium haloid salts on saturated solutions of potassium sulphate is proportional to the equivalent of the salt added (D. A. L.).

New Process for the Oxidation of Chromium Ores and the Manufacture of Chromates. J. Massignon and E. Vatel. *Bull. Soc. Chim.* 1891, **5**, 371-376.

THE present method of manufacturing bichromates consists in making an intimate mixture of finely powdered chromium ore with a salt of potassium or sodium and a large excess of lime, and heating it with constant rabbling in a reverberatory furnace to a very high temperature for six to eight hours in presence of a large excess of air. The mass is then cooled, lixiviated with water, and the solution treated with sulphuric acid and crystallised. The disadvantages attached to this process are that it necessitates (a), a large consumption of fuel; (b), expensive manual labour for rabbling; (c), loss of alkalis by volatilisation and combination with the gangue, and especially with the silica of the ore, thus rendering poor or siliceous ores unfit for treatment; (d), loss of ore which escapes oxidation.

The authors have worked out a new method based on an observation made by Pelouze that chromic oxide combines with lime forming a calcium chromite which absorbs atmospheric oxygen at the ordinary temperature, and is converted into the corresponding chromate.

The process is conducted as follows:—A mixture of the ore and limestone is finely powdered, well mixed, made into a paste with a concentrated solution of calcium chloride, and thoroughly incorporated with a paste consisting of lime slaked in a similar solution of calcium chloride. The lime or limestone is used in a proportion rather more than sufficient to combine with the whole of the chromium when oxidised to the state of chromic acid, and one equivalent of calcium chloride is used for every three equivalents of the total lime present. The mixture made in the manner described sets promptly, and is cut into cakes or bricks which are first partially dried in the open air, and then thoroughly dried and fired in a limekiln until the limestone is completely converted into caustic lime. The calcined bricks are piled in sheds and exposed to the action of the atmosphere for a month or more according to the temperature and humidity of the atmosphere, the supply of air, &c. If too much calcium chloride is added, the bricks will run together during the calcination instead of remaining open and porous, and the product will be hygroscopic. The presence of a small quantity of aqueous vapour in the air is essential, the oxidation being completely arrested in perfectly dry air; in presence of an excess of water, on the other hand, a retrograde action sets in, part of the chromic acid already formed being reduced to the state of chromic oxide.

When the chromium is completely oxidised the bricks entirely lose their green tin and acquire a yellow colouration. At this stage they contain calcium chromate, calcium chloride, excess of lime, and calcium carbonate, together with the ferric oxide and gangue contained in the ore, part of which also enters into combination with the lime.

The bricks are then systematically lixiviated with successive quantities of hot water, by which means the chloride of calcium (which is 100 times more soluble than the chromate) is obtained in a concentrated solution containing only small quantities of the chromate. The residue from this lixiviation is treated with sulphate or carbonate of soda or potash, filtered, and the solution crystallised at once or previously treated with sulphuric acid for the preparation of bichromates. Chromic acid may also be prepared from the residue by direct treatment with sulphuric acid. The chromic acid in the chloride of calcium liquors may be recovered either by again using the liquors in the process of manufacture or by precipitating them with a lead salt and separating the lead chromate (chrome yellow) which is thus obtained in a most economical manner (see also Eng. Pat. 2224 of 1891, this Journal, 1891, 547).

PATENT.

Improvements in the Electrolytic Production of Caustic Soda, Caustic Potash, and other Products from their Salts. C. J. Richardson, Clerkenwell, and T. J. Holland, Snodland. Eng. Pat. 2296, February 12, 1890. (Second Edition.) 8d.

IN the usual production of the above materials by electrolysis the hydrogen which is given off stirs up the liquid and products of electrolysis and at the same time it covers the cathode and polarises the cell. The inventors therefore cover the cathode with oxide of copper, which is reduced by the hydrogen and can afterwards be easily re-oxidised and used over again. When caustic soda or potash are required, the electrodes are horizontal, the cathode being at the bottom of the cell, while the anode is above it. The heavy caustic soda remains at the bottom, while the chlorine produced at the anode can be led away and used if desired. If hypochlorites be required, the plates are reversed, when the chlorine in ascending meets and combines with the caustic soda now produced above it. For small work, vertical electrodes may be used with porous diaphragms; the carbon anode may also be replaced by one of zinc, and the arrangement will then act as a voltaic cell, and in effecting the electrolysis will give an electric current which can be utilised.—E. T.

way, and the glass tube can be treated as if it were metal as far as soldering is concerned.

It may be united to iron, copper, bronze, platinum, or any metal which will take solder.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

On the Cause and Cure of the Brown Spots occurring during the Manufacture of Mirrors. A. Jolles and E. Wild. Zeits. f. angew. Chem. 1891, 266—268.

THESE brown spots are found to consist of silver sulphide formed by the action of free sulphur on the surface of the glass on the silver at the moment of deposition. This free sulphur is due to the decomposition, by the action of moist air and carbonic acid, of the sodium sulphide, which is reduced from the original sulphate by the furnace gases during manufacture. All glass, therefore, intended for the preparation of mirrors should be silvered as soon as possible after it is made; but if, through storage in a damp place or otherwise, free sulphur is feared, it should be boiled for one minute in a 10 per cent. solution of sodium carbonate, the glass being previously heated to avoid risk of fracture. The spots may also be dissolved, after removal of the varnish and silver, by a 5—10 per cent. solution of either sodium hydrate or carbonate. This treatment is found to answer perfectly without in the least degree injuring the polished surface.—F. H. L.

New Process for Soldering Glass and Porcelain.

THE United States Consul at Reichenburg, in a recent report, calls attention to a new process invented by Cailliet for soldering glass and porcelain to metals, which is exciting much interest there.

The part of the glass tube to be soldered receives first a thin layer of platinum by applying to the slightly warmed glass by means of a brush a quantity of neutral chloride of platinum and etherised oil of camomile. The oil evaporates slowly. As soon as the white, strong-smelling vapour has entirely disappeared, the temperature is raised to red heat, and the platinum is thus reduced and coats the glass with a thin layer of metal. The plated glass is then put in a bath of sulphate of copper and the coating connected with the negative pole of a sufficiently strong battery, when a ring of copper is deposited so thick and strong upon the platinum that it can be worked in any

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

The Testing of Bricks. M. Gary. Thonind. Zeit. 15, 501—503 and 521—523.

THE methods proposed from time to time and adopted by various testing stations for ascertaining the value of natural and artificial building materials for their intended use, differ appreciably in several respects, notably in the clause that relates to the test designed to determine the capability of the material to resist the disintegrating effect of cold.

The method adopted by the conference held in Munich in 1885 and in Dresden in 1886 includes the subjection of the test-piece to no fewer than 25 alternate freezings and thawings, and is of so severe a character that when it was tried by Bauschinger on 41 samples of artificial stone, it was found that only 3 samples resisted the ordeal completely and 8 partially (this Journal, 1890, 1037). The method of testing used by Bohme is as follows: 30 test-pieces are weighed and 10 tested in compression in the air-dried state. The remaining 20 are dried for 25 hours upon an iron hot plate, and again weighed, after which they are immersed in water for 125 hours (that time being found sufficient for their saturation) weighed again, and 10 tested in compression, while the other 10 are frozen for 24 hours either in air or under water. This time is found long enough to freeze them completely to the centre. They are then tested in compression and the whole of the results tabulated. In considering the table which is appended it will be understood that the hardness of the burning affects the density, hardness, and porosity of the bricks, and that though hardness is, generally speaking, advantageous, yet extreme hardness is objectionable as hindering the adhesion of the mortar. In cases where a very hard dense brick is required, the surface must be grooved, perforated, or channelled, so as to enable the mortar to adhere.

A study of the table leads to the following conclusions:—

(1) The strength of the specimens is independent of their specific gravity.

(2) A saturated brick is weaker than the same brick unsaturated, but the diminution in strength shows no relation to the amount of water required to saturate it, or to the hardness of the burning it has undergone. With regard to this fact, it may be said that as bricks usually contain no constituent soluble in water and no caustic lime, the slaking of which might give rise to internal strains, the decrease in strength observed can only be due to the water diminishing the friction between adjacent particles of brick at the moment of compression, thus allowing their freer movement and ultimate severance more easily than in the dry state.

Kind of Brick.	Colour.	Sp. Gr.	Hardness Moh's Scale.	Absorption of		Strength in Compression.

	Red	1.732	4	7.1	18.1	168	164	2.4	
	Light red	1.611	4	23.0	24.9	219	217	0.9	
	Light red	17.7	18.3	217	210	3.2	
	Dull red	1.660	24.8	143	143	0.0	

To make this hypothesis tenable a certain elasticity of the material must be postulated.

(3.) Freezing the specimens in air or under water diminishes their strength; the diminution is less in the latter case because the expansion of the frozen water external to the brick tends to set up strains, neutralising to some extent the internal strains produced by the solidification of the water in the pores of the test-piece.—B. B.

Manufacture of Slag Bricks in Montana. T. Eggleston. School of Mines Quarterly, U. S. A. 12, 189—193.

PATENTS.

Improvements in and relating to the Calcining of Carbonates for Cements and other Purposes. W. Darling Shotts. Eng. Pat. 10,127, July 5, 1890. 4d.

Hot furnace or similar slag is run into a "hogie" or vessel having a close crucible or retort mounted within it, in which is placed the carbonate to be calcined. The product can be used for making cement. An alternative plan consists in adding the carbonate to be calcined to the molten slag contained in an open or close vessel, the product being applicable as a cement or manure; for the former purpose 30—60 per cent. and in the latter 10—30 per cent. of limestone would be added. By using portable receptacles these operations can be conducted at a convenient distance from the furnaces.—B. B.

Improvements in Machinery or Apparatus for Crushing, Mixing, Grinding, and Delivering Materials for the Manufacture of Cement. N. W. Curtes and A. E. Carey, London. Eng. Pat. 10,918, July 14, 1890. 6d.

AN edge runner immersed in a tank is used for crushing the raw materials for the cement, and is provided with paddles depending from the ends of its horizontal axis which mix the crushed materials with the water contained in the tank. "The edge runner mill has a detachable grating on the top of the outer edge of the fan and removable roller paths." The slurry passes from the edge runner to a grinding mill of any suitable form, placed in the same tank, and thence is pumped to the drying floors. "Sieves or screens may with advantage be fixed between the edge runner mill and the grinding mill.—B. B.

The Application of Certain Waste Materials for the Production of a New or Improved "Mineral White" and Improvements in the Process of Manufacture. J. J. Lee, Manchester. Eng. Pat. 12,085, August 1, 1890. 4d.

See under XIII., page 713.

Improved Manufacture of Artificial Stone. A. J. Boulton, London. From L. Crote, Dresden, Germany. Eng. Pat. 5719, April 2, 1891. 4d.

Fifty grms. of dried wood pulp are steeped in "50 grms. of an ammoniacal solution of oxide of copper (100 parts in 500 parts of water)" and freed from the superfluous liquor; 500 grms. of "burnt magnesite" are mixed with 1,000 grms. of magnesium chloride solution (38 per cent.), and 350 grms. of zinc chloride solution (32 per cent.) and

the product dried and heated in closed vessels at a temperature insufficient to drive off any but an insignificant amount of hydrochloric acid. The mass after grinding is mixed with the prepared wood pulp, 5–20 per cent. of alumina being preferably added, forced into moulds and exposed to the air. "During the first 12 hours the water rapidly 'settles,' and the mass becomes strongly heated. During the succeeding 12 hours it partly retains its plasticity, while at the same time it is capable of being turned or polished." It then becomes too hard to work. The gradual hardening allowing of mechanical treatment, is the main feature of the process.—B. B.

Improved Apparatus employed in the Manufacture of Artificial Sandstone. O. Murray, London. From F. Zernikow, Odenberg, Germany. Eng. Pat. 8017, May 9, 1891. 6d.

ARTIFICIAL stone is made by mixing powdered quicklime with sand, slag powder, or similar material, ramming the mixture into moulds and slaking the lime by exposure to high pressure steam. In order to enable the moulds to resist the pressure exerted upon them by the expansion of the lime while slaking, they are supported one against another, wood or metal filling pieces being inserted between them and held in position by annular metal bands surrounding them, and by metal plates at each end securely bolted together. The whole arrangement is enclosed in a cylindrical vessel and high pressure steam admitted and maintained for several days.—B. B.

X.—METALLURGY.

The Destruction of Lead Pipes. Jour. f. Gasbeleuchtung, 34, 175.

See under I., page 683.

On the Genesis of Ore Deposits. W. H. von Streeruwitz. School of Mines Quarterly, U.S.A. 12, 181–186.

THE author reasons as to the cause of the existence of metals other than iron in a ferruginous siliceous deposit at great depths, and the absence of those metals in the same ore-bed at the outcrop. The hypothesis of heat and the separation by the degree of volatilisation is not applicable as the result is sometimes the reverse of what it should be. The same might be said of the precipitate and circulating current theories which have been in vogue for so long. The author's own experiments are then mentioned. When a crystal of ferrous sulphate was placed in a cold solution of an alkaline silicate thin nearly colourless threads began to grow and to rise to the surface where they became oxidised, spread about and deposited a brown ferruginous silicate resembling that of the iron outcrops which indicate ore veins. Salts of other metals do not act in this manner unless perhaps with extreme slowness, a year's growth being barely perceptible. When however these salts were used together with the iron salt the threads of iron silicate commenced to grow at once and to carry with them the other metals, which were sometimes discovered to be in the metallic state, especially the gold and platinum, and occasionally the silver and copper. Somewhat similar results were obtained when heat was applied or galvanic currents used.

The formation of agates is next considered. The experimental development of siliceous layers, instead of commencing with an outer zone and progressing towards the centre, invariably started with an acicular crystalline nucleus of silica, which thickened slowly into regular agate bands of various tints by deposits on the surface.

From these few experiments which are considered as incomplete the following points appear to be established:—

(1.) It is principally the iron which, in silico-ferruginous fissure veins, brought the other metals from greater to (by mining) accessible depths.

(2.) Most siliceous ore-leads, carrying also large quantities of iron and having silico-ferruginous outcrops, seem to be deposited from hot aqueous solutions of the metals and silicates.

(3.) Metals and metal combinations contained in the rock surrounding the fissures and crevices were probably leached out by the hot liquids contained in the fissures and precipitated on and combined with the siliceous iron growing up in the fissures.

(4.) The fissures could be charged with ore veins in a comparatively short time, since, no doubt, high temperature and galvanic currents existed in the fissures at the time of the formation of the ore-gangues.

(5.) In contact-gangues the precipitation and deposition of ores was materially facilitated by galvanic currents, caused by the contact of different rocks, and it is owing to the prevalence of galvanic currents that in most cases richer deposits at the intersection of two or more leads were formed.

(6.) The so-called "iron outflows" are frequently not the product of igneous eruption, but a deposition product from aqueous solutions, and alteration in the rocks contiguous to such outflows are not necessarily the result of eruptive agencies, but of a leaching process.

(7.) The formation of banded agates does not always take place (as generally believed) in the cavities of a rock, but can also occur free in solutions, and the thickness of the bands progresses from the centre outwards, although a reverse process by osmosis may be possible under certain conditions.—A. W.

An Assay Furnace. H. Wood. School of Mines Quarterly, U.S.A. 12, 186–188.

THE author advocates the use of muffle furnaces which are fed from the back, and describes one which he has used in Colorado with satisfactory results. Its approximate cost is about 100 dollars, and its advantages consist in the economy of fuel, the greater cleanliness, the rapid heating, and the large size of the muffles. The latter are made in two sizes,

the small, 9 by 15 inches, and the large, 13 by 15 inches. The accompanying drawings illustrate one of three furnaces accommodated by the same flue, which latter consequently appears rather large. For a single furnace the size of the flue would be 6 by 8 inches. The only disadvantage is the danger in feeding of breaking the cross-bar supporting the muffle: this is remedied by constructing knees or projections from the wall which serve as a rest.—A. W.

Manufacture of Slag Bricks in Montana. T. Egleston. School of Mines Quarterly, U.S.A. 12, 189—193.

A SERIES of cast-iron plates 1 in. thick is made in the shape of a T with bevelled edges and with a small piece with clutch-holes as shown in Fig. 1, plan and elevation. These

Fig. 1.

plates are set up on a series of bed plates so as to form five moulds, the end pieces being held in position by an extra plate placed as indicated in Fig. 2. The molten slag is then

Fig. 2.

run into these moulds from the ordinary slag pot. Directly it is set the mould frames are lifted up by means of hooks which fit into the clutch-holes and the bricks are piled together and allowed to cool slowly. The most convenient size for the bricks is 12 inches long by 6 wide by 6 deep, and they weigh about 55 lb. each. They are used extensively for building purposes, as they are as strong as stone except when submitted to shock, and also for the construction of kilns. The secret of the remunerative working lies in keeping the mould frames coated with clay-water and in removing them from the bricks directly the latter are sufficiently set to remain firm. When the bricks are allowed to cool in the moulds the cast-iron pieces soon become useless, but by the above plan the wear is unappreciable.—A. W.

The Treatment of Copper Slates at Mansfeldt. T. Egleston. School of Mines Quarterly, U.S.A. 12, 85—117 and 193—218.

THIS paper is a long and general account of the well known methods of treatment of the Mansfeldt copper-schist as employed at the works in that locality. Drawings of some of the furnaces are given and a number of analyses of the various intermediate and final products. These analyses and the statistics of the paper have been obtained from the two pamphlets published in 1881 and 1889 by the company owning the works, and the remaining information is the result of two visits to the district made for the purpose of the article. The details of the process have been extensively dealt with by the author, and the paper is one of which an abstract cannot suitably be made.—A. W.

The Calculation of Blast Furnace Slags as Practised in certain Works in Europe. A. J. Rossi. J. Amer. Chem. Soc. 12, 113—118.

THIS paper, in which the term "basic" is employed for a slag with one base and in the sense of a monosilicate, contains two examples for calculating a blast furnace charge from the same data by the usual long methods—the first being worked by reducing the bases and acid present to their respective amounts of oxygen, and the second by converting all the bases into lime. In the former case the author prefers the formula SiO_2 for silica and uses the old atomic weights.—A. W.

The Colourations of Metals. Report by H. Burghardt on a Memoir submitted by Loewenherz to the Ind. Soc. of Mulhon e. Bull. Soc. Ind. Mulhouse, 1891, 67—69.

LOEWENHERZ has studied, from a decorative point of view, the formation of surface-colourations on metals exposed to high temperatures. Experiments were made on iron, copper, and brass, articles composed of the two latter being very commonly surface-coloured in this manner. The temperatures at which particular colourations are produced, were determined by enclosing samples of the metals named, in a double-jacketed air-bath, provided with an arrangement for regulating the heat, and with a glass window for enabling the progress of the oxidation to be observed. In the case of copper the colourations range from pale orange to dark grey, in that of brass, from yellow-orange to green; the temperatures corresponding to these colourations are not stated in the original memoir. In the case of steel the time required for the production of a particular shade of colour, is, within certain limits, inversely as the temperature employed; thus, to produce a blue:—

At 180	there are required 3 days.
At 230	" " 50 hours.
At 290	" " 7—15 minutes.
At 380	" " 20 seconds.

The colourations may change to some extent during the cooling of the metal operated upon; moreover, they vary with the composition of metallic alloys, and in the case of steel, also the hardness. The author agrees with the opinion that the colour of hardened steel is by no means a sure index as to its quality.—E. B.

Physical Properties of some of the Alloys of Manganese, Copper, and Aluminium. Eng. and Mining J. 1891, July 11, 47.

THE German silver industry of the United States is one amounting in value to upward of six or eight millions of dollars annually. With a view to obtain if possible a cheaper and better article than German silver, Alfred H. Cowles and the author began some years ago to experiment with the alloys of copper and manganese. They found that whilst a pure metallic manganese could with difficulty be reduced by the ordinary methods, it could be cheaply reduced in the electric furnace. Through a long course of experiments they have perfected a substitute for German silver which is offered in the market under the name of "silver bronze."

Of course, it was no new thing to bleach copper with manganese. Dr. Percy, the discoverer of aluminium bronze, was also the discoverer or inventor of manganese bronze.

Following his written description several other makers have from time to time within the past thirty years attempted to produce a pure manganese bronze, but unsuccessfully. Some have even attempted its introduction into the German silver trade. But thus far it has been both too expensive to manufacture and of too corrodible a nature, as then made, to admit of a prolonged use.

In order to overcome the two prime difficulties, that of casting and that of corrosion, the authors have introduced a small percentage of aluminium into the alloy, and with excellent effect.

The successive steps that have been pursued are recorded on a list of upwards of 200 distinct mixtures of the several metals, copper, zinc, tin, lead, aluminium, iron, and manganese, and the metalloid silicon, with which experiments have been made to ascertain the tensile strength, ductility, colour, &c. The most important determinations derived from this list of experiments appear to be about as follows: That pure metallic manganese exerts a bleaching effect upon copper more radical in its action even than nickel. In other words, we found that 18½ per cent. of manganese present in copper produces as white a colour in the resulting alloy as 25 per cent of nickel would, this being the amount required to remove the last trace of red; that upwards of 20 or 25 per cent. of manganese may be added to copper without reducing its ductility, although it doubles its tensile strength and changes its colour; that manganese, copper, and zinc when melted together and poured into moulds behave very

similarly to the most "yeasty" German silver, producing an ingot which is a mass of blow-holes, and which swells up above the mould before cooling; that the alloy of manganese and copper by itself is very easily oxidised; that the addition of $1\frac{1}{4}$ per cent. of aluminium to manganese copper alloy converts it from one of the most refractory of metals in the casting process into a metal of the most superior casting qualities, and one whose non-corrodibility must in many instances be far greater than either German or nickel silver.

The "silver bronze" alloy which has been especially designed for rod, sheets, and wire purposes is of the following composition: manganese, 18 per cent.; aluminium, 1.20 per cent.; silicon, 5 per cent.; zinc, 13 per cent.; copper, 67.5 per cent. It has a tensile strength of about 57,000 lb. on small bars and 20 per cent. elongation. It has been rolled into thin plate and drawn into wire of 0.008 in diameter. Its electrical conductivity appears to be higher than that of German silver, and the hope is entertained that we have in it a material whose resistance will be such that it will afford the electrician better and cheaper wire for the rheostat than any other alloy.

A New Process for the Treatment of Cobalt Ore.

L. Pelleton. *Le Génie Civil*, 18, 1891, 373; *Proc. Inst. Civil Eng. Abstracts*, 105, iii. 74-76.

At the works of the Maletta Chemical Company, at Petit Quérilly, near Rouen, a new process for the treatment of the cobaltic manganese ore from New Caledonia has been successfully introduced by Mr. Herrenschmidt. The composition of the ore, subject to variation in certain of the less valuable constituents, averages:—

Peroxide of manganese.....	18.00
Protoxide of cobalt.....	3.00
Protoxide of nickel.....	1.25
Peroxide of iron.....	50.00
Alumina.....	5.00
Lime and magnesia.....	2.00
Silica.....	8.00
Loss in calcination.....	32.75
	<hr/> 100.00

The operations are entirely performed by the wet way, and the reagents used are to a large extent waste products arising in the treatment of the ore. The order of operation is as follows:—

1. *Solution of Ore.*—The ore, which is comparatively soft, is ground to a fine powder under edge-rollers, and is thrown into large pans containing a strong solution of ferrous sulphate, which is boiled by blowing steam through it. This dissolves manganese, cobalt, and nickel as sulphates, while the whole of the iron, including that in the ore, goes down as basic ferric sulphate together with the silica and alumina. The action continues for some hours, fresh ore being added as required, until the liquor when tested with permanganate is found to be free from dissolved iron. The contents of the pan are then blown over to a settling tank, where the clear liquor is separated from the ferruginous precipitate. The latter is then passed through a filter process, dried, and calcined, giving a powder which is sold as colcothar.

The ferrous sulphate employed in the above operation is prepared on the spot from scrap iron and nitre cake, or the residue, consisting of sodium sulphate and sulphuric acid, obtained in the manufacture of nitric acid. This gives, in addition to the green vitriol, sodium sulphate, which salts are separated by crystallising; the latter may also be utilised at another stage of the process.

2. *Precipitation of Nickel and Cobalt.*—The liquors containing cobalt, nickel, and manganese sulphates are transferred to stills made of slabs of the lava from Volvic, in Auvergne, and sodium sulphide is added. This precipitates cobalt and nickel as sulphides, with only a small proportion of manganese, the bulk of the latter metal remaining in solution by reason of the acidity of the liquor.

The mixed sulphides when separated are treated with a solution of ferric chloride which dissolves the manganese, giving a mixture of sulphide of nickel and cobalt nearly free from foreign matters. The manganese in the still liquors is converted into chloride by chloride of calcium, and precipitated by lime to be used in the Weldon process.

The sulphide of sodium used in this operation is obtained by decomposing the sulphate of sodium remaining from the ferrous sulphate with alkali waste in a closed vessel under pressure; the final residue of this operation being sulphate of calcium.

3. *Calcination of Cobalt and Nickel Sulphides.*—The precipitate of mixed sulphides, after the removal of the manganese, is subjected to a very careful roasting in a reverberatory furnace, which, if the operation is successful, results in its complete transformation into sulphates of cobalt and nickel soluble in water.

4. *Separation of Cobalt and Nickel.*—The product of the roasting operation No. 3, when dissolved in boiling water, is treated with chloride of calcium to convert the sulphates into chlorides, after which the liquor is divided. In one portion, A, the metals are precipitated as hydrated protoxides with lime, and, after washing to remove the calcium salts, the precipitate is diffused through water, and subjected to the joint action of a current of chlorine and of air under pressure, with the result of forming peroxides of nickel and cobalt. A second portion, B, of the original protochloride liquor is then added, and the whole is energetically mixed by blowing it up with steam. This has the result of reducing the peroxide of nickel in the A precipitate, which redissolves as protochloride with the peroxidation and precipitation of an equivalent proportion of cobalt from B, so that only nickel remains in solution, while the cobalt is entirely separated. The proportion of B is so chosen that the whole of the precipitated nickel is not dissolved, in order to ensure that the liquors contain no cobalt. Further additions of the solution are made in graduated quantities until the cobalt precipitate is completely free from nickel, when it is filtered, dried, and calcined for sale. The various liquors containing nickel are finally collected and treated with lime, the protoxide of nickel precipitated is separated by a filter-press, and after drying and calcination is ready for reduction.

The chlorine required in the operation is obtained from a portion of the ore which is used in the stills with hydrochloric acid, in the same way as an ordinary manganese ore. Cobalt, nickel, and iron pass into solution at the same time; the first two metals are recovered, while the ferric chloride is used in the treatment of the mixed sulphides.

The works as at present arranged are equal to the treatment of about 150 tons of ore per month, which corresponds to a yield of 4,500 kilos. of cobalt oxide and 1,850 kilos. of nickel. The former is worth about 25 frs., and the latter 3.50 frs. per kilo. The annual consumption of cobalt is estimated to be above 200 tons, or a value of about 300,000l.

The New Caledonian cobalt ore being very bulky it has been proposed, in order to save freight, to convert it into regulus at the mines. Experiments in this direction have been made at the same works, running down the ore with silica and iron pyrites in a water-jacket blast-furnace, with the result of producing a regulus with 8 per cent. of cobalt, in addition to iron and sulphur, and slags containing all the manganese, and only 0.02 per cent. of cobalt. This concentrated material it is proposed to treat in the same way, commencing, however, with operation 3, or the calcination of the mixed sulphides.

Uranium in the Black Hills. *Scient. American.*

URANIUM has been found in the Bald Mountain District in the Black Hills in such large quantities as to warrant the prospect of early production of uranium salts, as well as the metal uranium in the United States.

At present uranium mining is carried on only in two places in the world, namely, at Annaberg, Saxony, and Redruth, Cornwall, and the scarcity of the mineral has been the cause of its not being used for a very important purpose—the manufacture of steel.

In Europe uranium has only been found in pockets in form of pitch-blende, which is uranous and uranic oxide (10 per cent. of uranous and 51 per cent. of uranic oxide) combined with silica, lead, iron, and manganese; the other uranium ores appearing in such small quantities as not to be commercially valuable. Mr. Reinhold, who made an examination of the different uranium ores at Bald Mountain, S. D., found the following minerals in a depth of only a few feet, the rock being of the archæan formation:—

1. *Urand* (uraniumglimmer) embedded in the rock and the seams, in greenish yellow scales, the vein running vertically and being 40 ft. wide on the surface. An analysis shows it to be $(U_2O_5) 2 PO_4, Ca$. As a source for uranium this mineral cannot be used, the costs of concentrating being too high.

2. *Pitch-blende*. This mineral appears in seams, together with the above-mentioned scales. From all appearances the rock contains large quantities in greater depths, the conditions being analogous with those at Cornwall. Its composition is U_2O_5 with iron, lead, magnesia, and manganese, also silica.

3. *Uranium ochre* $(U_2O_5) 3 SO_4$ and uranochalcit $(U_2O_5, Fe, Ca) O SO_4, H_2O$, in large bodies of kidney-shaped form; and

4. *Trappit*, $3 U_2O_5, As_2O_5$.

All these ores, with the exception of the first one mentioned, may be converted into uranium salts, which are commercially valuable. The chloride, nitrate, and sulphate of uranium are used in the manufacture of stained glass, producing a greenish yellow tint, peculiar to them. They are also used in colouring porcelain (black porcelain), and to some extent in photography. Germany and France are the principal consumers, and lately the output in Europe has decreased, and the price of uranium advanced materially, its cost being now 10 dols. a pound. The amount of uranium consumed in the manufacture of glass and porcelain is, however, very limited.

Experiments and tests which have been made by the great steel and gun manufacturers in England and Germany have shown that the addition of a small percentage of uranium to steel increases its elasticity, and at the same time its hardness, to an extent that makes its use in the manufacture of guns, armour plates, &c., most desirable, but the scarcity of the material, and especially the great difficulty in reducing the ore to metal makes the price of uranium steel too high. If the recent discoveries in the Black Hills prove as important as present indications are that they will, it is likely that the metal can be produced cheaply enough to be used for this purpose.

PATENTS.

An Improved Method of Separating Sulphur from Sulphurous Pig Iron. G. Hilgenstock and J. Massenez, Hoerde, Germany. Eng. Pat. 11,328, July 19, 1890. 6d.

Iron containing much sulphur, and more especially the varieties of iron produced by the "Thomas" process, may be desulphurised by adding to the bath of molten metal at a high temperature a quantity of a manganiferous pig which becomes completely liquid at that temperature, and allowing the mixture to stand for some time. A slag of sulphide of manganese is formed, and its separation may be hastened by stirring or agitating the bath. The process is best carried out in a species of converter without tuyeres in the bottom; it is heated before the introduction of the molten metals, and a number of operations is performed successively in it before removing the slag.

The presence of an excess of manganese is advantageous; for instance, a successful desulphurisation is effected with the following mixtures: (a.) 60 tons of iron containing 0.15 per cent. of sulphur and 0.9 per cent. of manganese and 10 tons of iron with 4.5 per cent. of manganese and 0.02 per cent. of sulphur; (b.) 20 tons of iron with 0.3 per cent. of sulphur and 0.8 per cent. of manganese and 50 tons of iron with 2 per cent. of manganese and 0.04 per cent. of sulphur; (c.) 20 tons of iron with 1.2 per cent. of sulphur and 0.5 per cent. of manganese and 50 tons of iron with 3 per cent. of manganese and 0.02 per cent. of sulphur.

In all these cases the product contains about 1.5 per cent. of manganese and 0.03–0.05 per cent. of sulphur. The sulphide of manganese slag is mixed with limestone, &c., and smelted either alone or in conjunction with other iron ores for the production of a manganiferous iron, which is again available for use in this process.—S. B. A. A.

Improvements in Fluxes or Solutions for Coating Metals with Lead. A. M. Clark, London. From W. G. Horgan, New York, U.S.A. Eng. Pat. 12,624, August 12, 1890. 4d.

To coat sheet iron with lead it is freed from scale by means of hot dilute sulphuric acid, washed with water, and transferred to a vat containing a solution of lime or other alkaline compound, which serves to prevent oxidation and acts as a flux. The sheet iron is then placed in a dilute solution of zinc chloride containing on the average 20 lb. of oxalic acid and 10 lb. of sodium sulphite per ton of iron treated; these quantities depend, however, upon the quality of the metal. After this immersion the sheets are passed through melted lead and allowed to drain. A very closely adherent coating is obtained by this process.—S. B. A. A.

Improvements in or connected with the Coating of Metals or Metal Articles with other Metals or Alloys. W. P. Thompson, Liverpool. From F. J. Clamer, Philadelphia, U.S.A. Eng. Pat. 7777, May 5, 1891. 4d.

The inventor finds that articles of iron or other metals cleaned previous to plating with dilute sulphuric acid are left superficially covered "with a deposit of sulphuretted hydrogen," which is not removed by rinsing with water and prevents a proper union of the coating metal subsequently applied with the article taken. Sheets of metal, &c., treated by the process of Clamer (U.S. Pat. 363,593 of 1887) in which they are made the negative pole of an electric current in a cyanide bath, likewise have a deposit of cyanide of iron formed upon them which prevents the proper adhesion of the coating metal. By the present invention these deleterious deposits are removed by simply immersing the plates in a bath of muriatic acid, and subsequently in a saturated solution of equal quantities of zinc and tin in the same acid.

The inventor prefers to use the coating bath described in U.S. Pat. 283,077 of 1883, which is prepared by adding to one cwt. of molten lead about three ounces of sal-ammoniac, half an ounce of arsenic, three ounces of phosphate of lead or phosphorus, and half an ounce of borax or a similar flux. A small proportion of the mixed chlorides of zinc and tin may also be added.—S. B. A. A.

Improvements in the Treatment of Waste Tinned Steel or Iron. B. J. B. Mills, London. From W. L. Brockway, New York, U.S.A. Eng. Pat. 8111, May 12, 1891. 6d.

According to this invention waste tin plate, fruit cans, &c., are heated to 1,000° F. in a furnace in which a reducing atmosphere is maintained. It is claimed that in about three to seven minutes the tin and solder are completely separated from the iron and fall to the bottom of the furnace, whilst the iron is left in such a condition that after cleaning, cold rolling, and annealing, it is suitable for applications in which a tough high-class iron plate or foil is required.

—S. B. A. A.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

The Practical Aspects of Electric Welding. P. A. C. Perrine, D.Sc. The Elec. Eng., New York, **11**, 1891, 600; Proc. Inst. Civil Eng. Abstracts, **105**, iii. 81–82.

THE first welder actually sold was to the Roebblings, and in two years it made 370,000 splices in telegraph wire. This machine has been replaced by one large and seven small welders capable of working up to $\frac{1}{2}$ in. copper (40,000 watts) and during the year they have been set up, show an average of 1,000 welds per day. It is used by Messrs. Seaward and Son for uniting Norway iron and Swedish steel for carriage work; by the Pope Manufacturing Company for bicycle tires, the welds being finished in dies at the same heat. The Trenton Iron Company are now using it for joining their locked-wire rope, making, in fact, a solid bar of it for about 2 in. at the weld. It is also used for "spinning-rings" and steel axles up to $1\frac{1}{2}$ in. diameter, these standing the test of bending to 90° and back again. The heaviest work is probably being done at the Johnson Rail Company's works, and the hardest steel worked is that of band saws, and by this method even broken teeth are being replaced. Pipe-welding and bending is also being practised by several manufacturers by these means, the burrs being beaten down by rapid hammering, pneumatically driven or otherwise. In the Charlestown Navy Yard anchor chains up to 2 in. are being made, the links being in halves and the two sides welded at the same time and forged at the same heat, and electrically welded shells are manufactured to dimensions requiring a minimum amount of machining.

The electric welding process is rather a melting together of the two surfaces in contact than an actual welding; hence cast metals are not changed in their essential constitution at the point of junction, but rolled or drawn metal is practically reduced to its cast state, and therefore requires further treatment on the weld to bring it to a satisfactory condition. This is especially noticeable with heavy sections, and the gradual change of condition can be clearly perceived on both sides of the weld. Special additions are therefore provided for reheating joints in such metals and subjecting them to further hammering hot and in special cases also cold; but even this treatment still leaves much to be desired where great strength and pliability are required. This caution applies especially to copper and to the higher carbon steels; thus, by forcing the heat, however rapidly, a "burnt" steel can be produced electrically, and points rather to a rearrangement of molecules being the cause than any action of carbonisation, especially as the metal can be restored by careful forging.

The Direct Conversion of Heat into Electricity. R. J. Güleher. Sitzungsber. der Akad. der Wissensch. Berlin, **18**, 1891, 98; Proc. Inst. Civil Eng. **105**, iii. 82–84.

THAT electric currents can be developed by the direct application of heat to the junction of two different metals, which is the fundamental principle of the thermopile, was discovered by Seebeck in the year 1823. As regards the theory of the subject, Clausius suggested in 1880 that "by the molecular motion, which is termed heat, electricity is driven from one material to the other;" and Kohlrausch's theory of 1875 is somewhat similar in assuming that the electric current is in some way connected with the flow of heat, and *vice versa*. The discoveries of later years, culminating in the researches of Hertz, prove, however, that the electric current is merely the result of a certain vibratory motion of the luminiferous ether, and therefore, in accordance with the principles of the conservation of energy, a certain definite quantity of heat can be converted into a certain definite quantity of electricity without either loss or gain of energy, and it is this meaning that is given to the subject of this paper, conversion by a dynamo machine being termed "indirect."

Proceeding then to calculate the absolute efficiency of the ordinary means of producing the electric current by a steam-driven dynamo, the electrical energy developed is

shown to be only 6.4 per cent. of the energy existing in the coal burnt in the boiler: but even this low efficiency is 18 times greater than the direct conversion of heat into electricity as furnished by a No. 1 and Clamond thermo-battery, where the efficiency works out at only 0.35 per cent. of the mechanical equivalent of the gas burnt. If the high efficiency of the dynamo and steam-engine in themselves, as manufactured at the present day, be considered, it is clear that not much greater results can be expected in that direction, and the author has for some years been experimenting in other directions, therefore, for the direct conversion of heat into electricity.

The principal idea acted on at first was the heating of a certain metallic salt in a platinum crucible, which should form the positive pole of the element, and a carbon rod immersed in the molten substance, the negative pole; this substance would part with its oxygen to the carbon, and then be re-oxidised by contact with the air; and with this form of apparatus, a mixture of caustic soda and carbonate gave an electro-motive force varying between 0.475 and 0.4 volt, the "sodium blast" generated at the carbon point burning at the surface with its characteristic yellow flame, accompanied with slight explosions. For the similar potash salts the electro-motive force was between 0.4 and 0.31 volt, the flame being violet and the burning more violent, and forming a small display of fireworks. The adoption of lead oxide resulted in a momentary high electro-motive force, and then a sudden collapse of the platinum crucible, owing to the metallic lead reduced falling to the bottom and eating through the platinum. The author was surprised also to find that at the junction of the platinum connexion wire the crucible was also severely pitted, as the current had never been short-circuited, and he has no valid explanation to offer therefor.

After these experiments, the results of which did not promise any simple solution of the problem, the author set himself to improve, if possible, the thermo-battery, and for which purpose attention was directed to the following particulars:—

1. The adoption of durable materials.
2. That the electro-motive force and specific conductivity should be as high as possible.
3. Improvements in the form of the element.
4. Improvements in the application of the heat, *i.e.*, a higher efficiency in the production of the heat itself.

Subsulphide of copper, in spite of its high electro-motive force, gave on account of its high specific resistance, a weaker current than materials which gave only half its electro-motive force, and it was also found that, by a species of dry electrolysis, granules of metallic copper were formed throughout the body of the material, and its use was therefore discarded. A form of battery is described, and which was exhibited at the meeting, consisting of tubes of nickel and a special antimonial alloy, which was found to be very durable; this consisted of fifty elements in series united in one casing, and gave an electro-motive force of 1.5 volts, and an internal resistance, when hot, of 0.4 ohm, with a consumption of $7\frac{1}{2}$ cubic feet of gas per hour, and the absolute efficiency is 1.08 per cent., or three times that of the existing thermo-batteries. Such a battery is almost exactly equivalent to two Bunsen elements, and though it is far below the dynamo in efficiency, still it may be suitable for various small installations and for experimental work, owing to complete absence of polarisation, as the electro-motive force does not fall on short circuit. The durability is enhanced by a regulator applied to the gas-supply to prevent any accidental overheating.

The author concludes by stating that he hopes to exhibit at the Frankfort Exhibition two cells which are the outcome of still later researches, and in which the efficiency has been raised to over 5 per cent., and thus almost capable of competing with the dynamo. The description of the construction is withheld; but it is stated that one form is capable of continuously furnishing current for eight 16 candle-power lamps at a consumption of 4.5 lb. of coke per hour. This success the author hopes still further to advance, and thereby exceed the efficiency of the dynamo system as a converter of heat into electrical energy.

Improvements in the Electrolytic Production of Caustic Soda, Caustic Potash, and other Products from their Salts. C. J. Richardson, Clerkenwell, and T. J. Holland, Snodford. Eng. Pat. 2296, February 12, 1890. (Second Edition.) *8d.*

See under VII., page 699

Improved Electrolytes for Primary Batteries. W. Wright, New York, U.S.A. Eng. Pat. 8394, May 30, 1890. *6d.*

AN aluminium salt is used in combination with bichromate of soda and sulphuric acid, or with other salts or acids. Such an electrolyte is said to be powerful and cheap.—E. T.

Improvements in Insulating Compositions for Electrical Purposes. A. N. Ford, London. Eng. Pat. 11,130, July 17, 1890. *6d.*

Wood fibre, flax, cotton, or other fibrous material is coated repeatedly with linseed oil which has been oxidised by heating for some time with litharge or other oxidising agent to about 350° F., the whole being air-dried between each coating. After the weight has been thus increased 50 to 200 per cent. the mixture is ground up to a homogeneous mass, mixed with, say, 25 per cent. of gutta-percha or india rubber, again worked up, and finally rolled into sheets or blocks of convenient shape. There is thus great economy of gutta-percha or india-rubber.—E. T.

Improvements in Electro-Magnetic Separators for Extracting Metal from Slag and the like. P. W. Askham and W. Wilson, Sheffield. Eng. Pat. 11,690, July 26, 1890. *8d.*

A NUMBER of electro-magnets are placed, in lines parallel to the axis, on the outside of a non-magnetic drum, so that their poles project through into the latter. The drum is inclined to the horizontal, and a mixture fed in at the higher end works its way in consequence to the lower end when the drum is rotated, and there falls into a shoot. In its passage, however, it comes in contact with the poles of the magnets, and the magnetisable portion sticks to these poles and is carried nearly to the top of the drum. As each series of magnets arrives at this position the electric current is turned off for a short time by a suitable commutator, and the material that was sticking to the poles drops into a trough supported a little above the axis of the drum, and is carried by a revolving worm to the outer end of the trough, and thus to a second shoot.—E. T.

Improvements in the Manufacture of Lead Wire suitable for Electrodes and other Purposes, and in Electrodes made of such Wire. J. and L. Legay, Levallois-Perret, France. Eng. Pat. 11,919, July 30, 1890. *8d.*

A SERIES of equidistant grooves are made in two similar rollers, such that the width of each groove is equal to the thickness of the wall between it and the adjacent ones. The two rollers are then mounted so as to revolve with parallel axes, and with the walls of each roller fitting into the grooves of the other. The rollers thus act as a series of circular shears, and lead sheet is cut by them into strips or wires. The shape of such wire can be altered by modifying the shape of the ends of the walls and bottoms of the grooves.

Electrodes are made by twisting such wires or by making cables of them and supporting in any suitable manner. Thus two cables, one right and the other left-handed, are wound side by side over two horizontal bars forming the top and bottom of the future plate, in a sort of double thread, the juxtaposition of the opposing twists of the two cables being said to prevent buckling.—E. T.

Improved Compound for Electric Insulating Purposes. W. Sinclair, Hull, and B. S. J. Mackay, Belvedere. Eng. Pat. 12,013, July 31, 1890. *4d.*

THE insulating compound consists of sulphur 7 lb., clean pipeclay 1½ lb., slate dust 1½ lb., paraffin wax 2 oz., and a metallic oxide, say that of copper or iron, 5 lb. The oxide alters the colour, has a slight cohesive action, and increases the weight for commercial purposes.—E. T.

Improvements in the Methods of and Apparatus for Use in Recovering Tin from Waste Tinned Iron or Steel. W. Beatson, Rotherham. Eng. Pat. 12,200, August 5, 1890. *8d.*

THESE improvements are in the details of the process described in Eng. Pat. 11,067 of 1885 (this Journal, 1886, 493). Waste tinplate is stripped by exposing it to the action of an electric current whilst immersed in a hot solution of caustic soda or potash. The solution (which contains about 3 lb. of alkali per gallon) is held in an iron tank provided with a series of iron plates connected with the cathode of the circuit, and with a series of iron pillars, on which are slung sheet-iron boxes, having two sides constructed of wire gauze and connected with the anode. The scrap tinplate is charged into these boxes, which are then immersed in the soda solution and the current passed. The tin is deposited upon the iron plates forming the cathode, and is subsequently scraped off, pressed into flat cakes, and purified by placing it in a strong solution of sulphate or chloride of tin and electrolytically redepositing it upon a revolving iron cylinder, on which it is condensed by tin rollers pressing on it.—S. H. A. A.

Improvements in or Relating to Electrical Batteries. E. Buffet, Brussels, Belgium. Eng. Pat. 12,763, August 14, 1890. *4d.*

THE object of this invention is to produce in the cell, oxide of zinc which has a higher marketable value than zinc itself. For this purpose the zinc is immersed in plain water in the porous pot, and a carbon electrode of large surface is placed in the outer vessel in the following solution: sodium nitrate 750 grms., sulphuric acid ("60° by the acid poise") ½ litre, distilled water 2½ litres. During action, oxide of zinc is deposited as a white mud in the porous pot.—E. T.

Improvements in Secondary or Storage Batteries. S. C. C. Currie, Philadelphia, U.S.A. Eng. Pat. 3331, February 24, 1891. *8d.*

A CONICAL rod of brass has a shoulder or expansion at its base to serve as a support for a woven tube of asbestos, which fits over such shoulder and reaches a little beyond the end of the conical portion which it encloses. Fused chloride of lead or other suitable salt is poured into the space between the tube and the cone. When cold, the latter is withdrawn, and its place supplied by melted lead. The chloride is then brought to the active state by electrolysis or other suitable method. As many of these rod-like electrodes as are required are then mounted vertically on lead connecting pieces at the bottom of the cell. The asbestos tube prevents damage from disintegration or scaling.—E. T.

An Improved Method of Electro-Plating Wire. T. L. Hemming, Birmingham. Eng. Pat. 5508, March 31, 1891. *6d.*

TWO drums or swifts are immersed in the electro-plating tank and the wire wound from one on to the other. The banks of wire make connection to rings in the drums, while the current is led into these rings by suitably supported brushes. The remainder of the specification relates to details of the bearings of the drums, methods of driving, &c.—E. T.

Improvements in Apparatus for Electrolytic Decomposition. C. Kellner, Vienna, Austria. Eng. Pat. 5547, March 31, 1891. 8d.

THE apparatus is made like a filter-press, *i.e.*, with a number of frames of suitable material separated by porous diaphragms. Successive frames are alternately anode and cathode cells, the anode cells having an overflow to a channel on one side and the cathode cells to one on the other. All are supplied by a common channel at the bottom to which the diaphragms do not reach. The electrodes are carbon rods, so mounted and connected electrically as to be easily removed individually without stopping the working of the apparatus. When sodium chloride is being electrolysed, sodium hydroxide flows off into one side channel, and chlorine and chlorinated liquor into the other.—E. T.

Improvements in or Connected with Means or Apparatus Employed in Electrolysis. E. A. Le Sueur, Ottawa, Canada, U.S.A. Eng. Pat. 5983, April 7, 1891. 8d.

A LARGE tank is half filled with the solution to be electrolysed. One, two, or more inverted cylindrical pans are placed in this with one edge of each raised so as to tilt it from the horizontal. The upper part of the pan contains a large positive electrode of gas carbon mounted so as to be easily raised or lowered in it. The mouth is covered with a diaphragm of parchment or other suitable material, immediately below which is the negative electrode of wire gauze. The caustic soda is thus formed in the large tank, the hydrogen readily escapes from the under surface of the diaphragm owing to its inclined position, and chlorine is collected from the top of the pan. Devices for sealing, making the electrical connections so that each pan can be attended to independently of each of the others, attaching the diaphragms, leading away the gases, &c., are described in a long specification with many drawings.—E. T.

Ozonizing Apparatus. J. Guenet, Paris, France. Eng. Pat. 6374, April 14, 1891. 6d.

See under XX., page 725.

Improvements in and relating to Voltaic Cells. G. Wester, Munich, Bavaria. Eng. Pat. 7168, April 25, 1891. 6d.

A BATTERY cell, resembling an ordinary Leclanché, has the carbon of the latter replaced by copper in sulphate of copper, the zinc rod being in sal-ammoniac. The porous pot is specially prepared by dipping to one-third its height into paraffin wax and then filling with aqueous solution of ammonia. This is then poured out and replaced by copper sulphate, which is in its turn poured away and the pot allowed to dry. In this way a doable sulphate of copper and ammonia fills the pores, and being insoluble in either of the battery solutions, prevents them from mixing. In one particular case the E.M.F. was 0.812 volt and resistance 4 ohms.—E. T.

Improvements in Storage Batteries. G. A. Washburn, Cleveland, U.S.A. Eng. Pat. 7715, May 5, 1891. 6d.

A LOOSE lining of perforated lead is placed in a containing vessel, the space between the vessel and lining being filled with active material. Inside the lining is placed a porous pot containing more active material, connexion being made to the latter by perforated tubular lead conductors. In the centre of the pot is a large rectangular lead tube; when the active material expands, this tube alters in shape to accommodate the expansion and thus preserves the porous pot. The electrolyte is placed in the tubular conductors and in the space between the porous pot and the lead lining.—E. T.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

Contributions to the Study of the Theory of Bleaching by Exposure to Air. A. and P. Buisine. Compt. Rend. 112, 738—741.

WHEN bees'-wax is exposed in thin layers to the air and to direct sunlight it is quickly rendered colourless, but in the dark, in presence of a free supply of air, oxygen, or ozone, no decolourisation whatever is effected, even after a long time. In presence of sunlight oxygen, and especially ozone, destroy the colour very rapidly, but the presence of oxygen is not absolutely necessary; when the wax is exposed to sunlight *in vacuo*, or in an atmosphere of carbonic anhydride, it is bleached, but much more slowly than in the presence of air.

The composition of the unbleached wax differs considerably from that of wax which has been bleached by exposure to air and sunlight; the latter contains a slightly larger percentage of free acids, but a large proportion of the unsaturated acids of the oleic series and of the unsaturated hydrocarbons in the crude wax have disappeared; this fact shows that in the bleaching process not only does the colouring matter suffer total combustion, but the unsaturated acids and the unsaturated hydrocarbons are converted into saturated compounds by the fixation of oxygen. This is also the case with other fatty substances such as suet, and the reason why the addition of 1—5 per cent. of suet to bees'-wax causes decolourisation to proceed more quickly is because the suet, in its oxidation or combustion, aids the destruction of the colouring matters; the addition of a small quantity of other oxidisable substances, such as essence of terebenthene, also hastens the action, so that it would seem that the destruction of the colouring matter is due to the formation of ozone by the oxidation of the added substance.—F. S. K.

Adulteration and Analysis of Bees'-Wax. A. and P. Buisine. Bull. Soc. Chim. 1891. 5, 654—660.

See under XXIII., page 729.

African Palm Oil. Kew Gardens Bull. July 1891.

THIS Bulletin, in an article on the palm oil industry of the Western Coast of Africa, has the following:—

Of all the products of the Gold Coast the *Elvis guineensis* is undoubtedly the most important to the native. The fruit supplies him with a favourite food and two important articles of commerce; with the leaf stalks he builds his house and barn and thatches the roof with its leaves, and from the stem he extracts a pleasant and (sometimes) intoxicating drink. The tree prefers a moist soil, flourishing in the warm, damp valleys, where it grows in extensive forests. It has never been made the object of systematic cultivation, but, as far as can be ascertained, it begins to bear in its fourth or fifth year, increasing till its fifteenth, and continues to bear at least 60 years. It produces from four to seven bunches of nuts every year. As the "fatness" of the nuts (*i.e.*, the amount of oil contained in the fibre) differs greatly according to soil, the quantity of oil varies from three gallons per year in a moist soil to one gallon in dry. These nuts have a fibrous covering which contains the famous palm oil. Three varieties of the tree are distinguished, having orange, red, and black nuts respectively, the first giving the finest oil but small kernels, and others less oil but larger nuts. When the bunches of nuts are ripe they are cut and thrown into a hole in the ground till a sufficient quantity is collected to be made into oil. During this time the nuts appear to undergo a small amount of fermentation, and the produce is "hard" oil, the fresh nuts giving "soft" oil, which fetches a better price in the European markets. The quality of the "hard" oil is also deteriorated by the dirt which becomes mixed with the nuts while stored, to separate which no care is taken. When a sufficient quantity has been collected the nuts are boiled till the fibre is softened;

they are then heaped up in stone troughs specially prepared for the purpose, and beaten with sticks till the fibre is loose. The heap of nuts is then covered with plantain leaves and left for 12 hours, during which time great heat is developed and a quantity of oil runs off. The nuts are then washed in hot water and the fibre separated and squeezed by hand. The oil is then boiled to separate it from the water taken up in the washing.

This process is defective at every stage. To produce the finest quality and the largest quantity of oil the nuts should be treated when just ripe and fresh gathered from the tree. They should not be allowed to ferment, as this darkens the colour of the oil and causes it to harden. The separation of the fibre by beating and hand squeezing is slow and gives very imperfect results, and should be replaced by machinery in the first stage and hydraulic presses in the second. At present quite 25 per cent. of the oil is lost, first by imperfect separation of the fibre, a large quantity of which is left adherent to the nuts, and second by want of power in the squeezing, which fails to extract the whole of the oil. Finally, the last boiling further darkens the oil, as palm oil changes colour according to temperature. Pure fresh palm oil has an agreeable smell (it has been described as resembling that of plum cake), and is of a bright orange colour; but the oil of commerce, owing to faults of manufacture, has a stink absolutely indescribable, and every shade of colour between golden yellow and black. In the Western province the quality is further deteriorated by adulteration. At Salt Pond a peculiar fine red earth is used for mixing by the middlemen. In the Chama district the oil is mixed with over-ripe plantains and sour kanki. Acera may be considered the dividing line of the two sorts, the oil made in that district and to the eastward being soft, that made to the westward being hard. The soft oils are in general purer than the hard; these being less able to incorporate foreign substances, the adulteration is almost confined to the mixture of water. To show the effect of adulteration nothing more is necessary than to compare the position of Lagos oil (which is the purest known) with that of Gold Coast oil on the European market. When Lagos oil sells for 22*l.* 10*s.* per ton, Acera oil (which includes Adjah and Quittah sorts) fetches 19*l.* 10*s.*, and Salt Pond (including Wimbah, Appam, and Chama sorts) 18*l.* only, or 20 per cent. less than Lagos sorts. No doubt some of the superiority of Lagos oil is inherent in the article, but having in view the amount of adulteration in the oil from the Gold Coast, it is not unreasonable to expect that the production of a purer oil and the adoption of the Lagos "cold" process of manufacture (as distinguished from the Gold Coast "hot" process) would approximate prices. It is impossible to pass from this subject without referring to the fluctuations in the price of palm oil which have occurred during the last few years. It is the difficulty of transport that keeps the price on the Gold Coast at such a height as renders the present state of the markets in Europe unprofitable to the exporter, although the grower can produce it at a cost which would enable him to sell it with profit at 3*d.* to 4*d.* per gallon. Allowing 300 gals. to the ton, the cost to the exporter would be 3*l.* 15*s.* to 5*l.* per ton, which, after paying for caskage, shipping, &c., and allowing 1*l.* per ton for transport from the plantation to the beach, would enable him to place it on the European market at 13*l.* per ton. In view of the increasing use of other fats, displacing palm oil in many directions, the inhabitants of the colony have to face the probability of the price of palm oil touching 15*l.* to 14*l.* per ton, and have the right to call upon their Government to perform its obvious duty by putting the roads in such a condition as to enable them to transport their produce at a reasonable cost, and to prevent their staple produce being driven from the market to the ruin of their trade. After the manufacture of the oil the nuts are still valuable, as they contain the well-known palm kernels. For every ton of palm oil there should be 2½ tons of clean palm kernels, and yet we find that the exports of this article are much below those of the oil. The direct loss to the colony is enormous, and arises from the same causes as diminish the export of oil. Machines have been invented by Gummell and others for the purpose of rapidly breaking the nuts, but they can never

come into general use until it is possible to move large weights in carts along roads adapted to the purpose, as will be evident when it is considered that under present conditions four men are required to carry, on their heads, sufficient nuts (2 cwt.) to produce 56 lb. of kernels, the value of which varies from 1*s.* 9*d.* to 2*s.* 3*d.* Owing to this cause 100,000*l.* worth of this one article are annually wasted. The palm kernels are exported to Europe, where the oil is extracted, but this might be done on the coast if it were possible to put oil mills on the plantations or to convey nuts cheaply to central mills, and would probably be found more remunerative than the exportation of the kernels. The average yield of the kernels being 30 per cent. of their weight in oil, the utilisation of the whole estimated crop would produce 8,700 tons of oil per annum, which at the price of cocoa-nut oil (which it closely resembles) would be worth to the colony over 175,000*l.* To this must be added the value of the cake after the expression of the oil. The brown or black oil made by the process now in use in the country is not worth exporting, as it can be only slightly bleached, and is therefore useless for soap-making.

PATENTS.

Improvements in the Manufacture of Soap. R. Cuffe, London. Eng. Pat. 10,953, July 14, 1890. 4*d.*

A hard neutral potash soap is obtained by the addition of 2 per cent. of chloride of potash and 5 per cent. of carnauba wax to stearate of potash. This soap possesses, according to the patentee, curative and prophylactic properties for gout, caustic potash and chloride of potash having no injurious effect on the blood, but are beneficial in neutralising uric acid. When ordinary alkaline soda soap is used the caustic soda set free is absorbed by the blood, on which it has injurious action.—K. E. M.

Plates for Oil and other Presses. W. C. Leechman, Colombo, Ceylon. Eng. Pat. 9526, July 19, 1890. 6*d.*

With a view to introduce good drainage on the surface of press plates by eliminating the clogging of the presses and the damage to the cloths, the patentee describes the arrangement in the press as shown in the accompanying figure, which represents a vertical section of a part of a press fitted with plates according to invention.

PLATES FOR OIL PRESSES.

AA, the plain press plates now generally in use; BB, extra plates grooved on one side; holes lead from the grooves to the ungrooved surface; CC, finely perforated thin plates; these are not required for moderate pressures of about half a ton to the square inch, but necessary for high pressures, when the fine perforations of the thin plates "throttle" the orifices of the holes in the grooved plate; DD, filter cloths; EE, rings with inclined surfaces, to prevent the material from spreading outwards.—K. E. M.

Improvements in the Manufacture of Soap. J. Baptista, Philadelphia, U.S.A. Eng. Pat. 11,360, July 21, 1890. 4d.

By the action of caustic soda solution on white rosin the inventor obtains a jelly, one pound of which is mixed with about one gallon of cotton-seed oil, and the mixture boiled. A suitable mineral oil is added in the proportion of half a gallon to one barrel and half a pound of chloride of lime dissolved in a little water to every 20 barrels of the soap stock mixture described above. This mixture after well boiling through is now ready to be introduced into the soap copper, where 25–35 per cent. of it is used in the composition of the boiling soap.—K. E. M.

An Improved Manufacture of Saponifiable Fatty Matter from Wool-Fat. L. Roos, Frankfurt-on-Maine, Germany. Eng. Pat. 12,373, August 7, 1890. 4d.

COMMERCIAL dark brown coloured wool-fat is partially saponified by alkaline solutions and the resulting emulsion mixed with water. The cholesterines, &c., separate from the saponified materials, which latter either immediately or after being repeatedly subjected to the process may be decomposed by dilute acids yielding a light coloured fatty product suitable for the manufacture of soap. The unsaponified cholesterines thus separated can be employed for the manufacture of wax and other purposes.—K. E. M.

Improvements in or Appertaining to the Production of Odourless Wool Grease. C. A. Feuerlein and J. C. Lahusen, Dehnenhorst, Germany. Eng. Pat. 13,634, August 30, 1890. 6d.

THE inventor substitutes sulphurous acid for the mineral acids generally used in the recovery of wool grease from the waste water from wool washing and combing factories. The wool grease obtained from the grease sludge precipitated by mineral acids from the soapy water has an unpleasant odour due to sulphuretted hydrogen from the sulphides contained in the wool yolk. This odour is avoided by the use of sulphurous acid which converts the sulphides into sulphites, hyposulphites, and sulphur.—K. E. M.

Improvements in the Manufacture of Soap Tablets. F. W. Ostrom, Bridgeport, U.S.A. Eng. Pat. 14,339, September 11, 1890. 8d.

THE invention consists in a device for compressing soap by the stamping machine around a suitable anchor provided with an eye which extends outside the soap and by which the tablet may be fastened to a chain. For details consult drawing accompanying specification.—K. E. M.

Improvements in Soaps for Diseases of the Skin. C. R. Illingworth, Clayton-le-Moors. Eng. Pat. 17,275, October 29, 1890. 4d.

BORACIC acid is incorporated into a super fatted soap containing no free alkali with a view to combine cleansing and disinfecting action upon the skin.—K. E. M.

XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

The Composition and Manufacture of Chromium Pigments. C. O. Weber. Dingl. Polyt. J. 279, 139–144, 210–213, 232–235, and 284–287.

I. PIGMENTS CONTAINING CHROMIC ACID.

FOR the preparation of lead chromates, both soluble and insoluble lead salts are employed, but while the latter are much cheaper to use, it is universally admitted that the best chrome yellows are only to be prepared from the acetate, no other salt giving such a large variety of shades as well as other desirable physical properties. The lead acetate is preferably made from litharge in a lead-lined hemispherical iron pan fitted with a steam pipe passing to the bottom; in this is placed about half the necessary amount of acetic acid of 30 per cent. strength (6° B.), the pan being of such a size that it is about one-third filled. The liquid is then heated to the boiling point, and the litharge, which has been previously reduced by grinding under edge-runners with water to a fine cream, is run in through a sieve with constant stirring. Steam is again turned on for a few minutes, and when the liquid begins to boil, solution rapidly takes place. To convert this basic salt into the neutral acetate, the remainder of the acid is added gradually until a few drops of the liquid no longer give a precipitate with a 5 per cent. solution of mercuric chloride.

Basic lead acetate, $\text{Pb}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 2 \text{Pb}(\text{HO})_2$, has been recognised for a long time as the best source of chrome oranges, and later experiments have shown that in spite of certain difficulties in the manufacture, it is also admirably adapted for the manufacture of other chromes varying in shade from the softest lemon to the deepest scarlet; in fact, that neither in cost nor in beauty of shade can it be beaten by any other lead salt. It is prepared in the previously-described pan, which for this purpose should hold about 300 litres, by taking 76 kilos. of 30 per cent. acetic acid and heating to about 90°, the admission of steam being so regulated that the temperature remains above 70°. 120 kilos. of litharge are then added in the state of a cream as in the preparation of the neutral salt, a stiff brush being constantly worked about in the sieve to hasten the process. When all the litharge has passed through, the sieve is washed out with hot water, the brush being used all the time. The success of the operation depends largely on the speed of addition of the litharge and on the fineness of the sieve, which should not be less than No. 120, and great care must be taken that none of the cream is poured directly into the acid, as in this case, hard lumps are formed which fall to the bottom and escape the action. Thorough stirring must also be kept up the whole time, until the mass is seen to thicken and to change in colour to a pure white; should it then prove too thick for further manipulation, more hot water is added, but the addition of much water, whether hot or cold, is to be avoided as it slows the action. When the reaction is complete the pan is covered with a wooden lid and allowed to stand 12 hours. It should then form a very hard white mass in which no lumps and unchanged litharge are visible.

For conversion into chromate the basic acetate need not be dissolved in water, suspension being sufficient, and this may be attained by working it through a fine sieve by the aid of a brush as previously described, but seeing that the amount of metallic lead which is present in all commercial litharge is apt to spoil the shade of the chrome, it is better to run it through an ordinary paint mill, when the free lead will be found to remain in the grooves of the stones, and can easily be removed at the end of the operation. It is advisable to set up the mill in such a position that the cream after grinding can run direct into the precipitating tank.

The litharge employed for the manufacture of either normal or basic acetate must be as pure as possible, the presence of small amounts of copper being extremely prejudicial. To test for copper, 10 grms. of the litharge should be treated in a beaker with 20 cc. of ammonia, to which a few

drops of nitric acid have been added; after thorough stirring the whole is allowed to rest for six hours and filtered. The filtrate is acidified with acetic acid and a few drops of a 10 per cent. solution of potassium ferricyanide added, if anything more than a slight brown colour is noticeable, the sample must be rejected. Of great importance also is the physical condition of the litharge, and in all cases a laboratory experiment on the ease of conversion into the basic acetate should be tried before the substance is used on the large scale.

A.—THE CHEMISTRY OF LEAD CHROMATES.

Normal lead chromate, formed by the decomposition of lead acetate by potassium bichromate, although possessing when freshly precipitated a very brilliant sulphur-yellow colour, is rarely employed in commerce except for the production of green lead glass. The reason of this lies in the fact that during the prolonged washing necessary to free it from acid, its colour is liable to alter to an orange yellow, which will not bear dilution without giving very unpleasant and dirty shades. The exact cause of this change has yet to be explained, but it seems probable that it is due to a crystallisation of the chromate. It is not even possible to prevent it with certainty, but it is advisable to work with at least 5 per cent. excess of lead, to use the solutions as dilute and cool as possible, and to keep stirring during and for some time after the precipitation. Yellows of similar chemical composition show very different shades, according to the amount of the excess of lead present during the precipitation, being the more brilliant in colour the greater the excess. If the precipitation takes place in the presence of sufficient sodium carbonate to neutralise the whole or greater part of the nascent acid, the resulting chrome shows much less tendency to change. The American "chrome yellow for the production of chrome green," a pigment which owing to the peculiarity of its shade is unsaleable as a yellow, but is better adapted for mixing with Prussian blues than any other chrome, owes its non-liability to change to the large excess of lead present during precipitation as well as to the neutrality of the solutions. In this case the absence of free acid is attained by adding one part of crystallised tartaric acid to ten of the bichromate in concentrated solution, the result being a mixture of the normal salt with chromium chromate.

On the large scale the manufacture of lemon chromes, of the formula $PbCrO_4$, by the action of a large excess of lead during precipitation with the bichromates becomes impossible owing to the great expense. They are usually prepared by the simultaneous action of chromates and sulphates on the lead salts, the larger the proportion of sulphate the paler the shade of the resulting pigment. These lemon chromes are said by the manufacturers to be "chemically pure," the lead sulphate being regarded as an integral part of the substance and not as an adulterant. The probability is that they consist of a double compound of lead—a sulpho-chromate—in spite of the facts that on precipitation the chromate falls first, and that on treatment with sodium thiosulphate, lead sulphate is extracted. This first peculiarity is due simply to the heat of formation of the chromate being much greater than that of the sulphate; for simultaneous precipitation could only be expected if the two amounts of heat were nearly identical. The lead sulphate is also only partially soluble in thiosulphate, and the shade of the resulting chrome is different from any directly prepared. The colours of the different lemon chromes cannot be imitated by mixing together lead chromate and sulphate, however intimately. These complex chrome yellows are much less liable to change of colour during washing than the simple chromate, but it is still advisable to precipitate them in the presence of a small excess of lead acetate.

Although possessing the same chemical constitution ($PbCrO_4 + PbSO_4$) lemon chromes prepared by different processes possess very different shades of colour and also vary considerably in their other physical properties, such as hardness and covering power. In Table I. are given five different mixings for the production of such chromes, and it will be found that the colour becomes regularly darker from 1 to 5, while 1 yields hard and brittle lumps which gradually

get more flocculent and spongy till 5 is reached. The first are also more suitable for lithography and the preparation of coloured papers, while the latter are best used in oil as paints.

TABLE I.

—	1.	2.	3.	4.	5.
$Pb(O_2C_2H_3O_2)_2 \cdot 3Aq$	100	400	100	400	400
$K_2Cr_2O_7$	73.75	73.75	73.75	73.75	73.75
H_2SO_4	49
$Al_2(SO_4)_3 \cdot 18Aq$	160.5	..	160.5	..
Na_2SO_4	71.0	..	71.0
Na_2CO_3	26.5	26.5

The cause of these differences evidently lies in the diminishing acidity of the foregoing formula, this being one of the most important factors in the manufacture of chromes. The nature of the free acid is also of great importance, and if the lead acetate is replaced by the nitrate the resulting shades as well as the other properties of the chromes become very different. Free nitric acid also causes considerable swelling of the chrome, the mass becoming quite spongy in appearance; and as this swelling is in proportion to the amount of acid present, if the acetate in Table I. be replaced by the nitrate, 1 will yield a very bulky product, 5 being close and heavy. Many consumers value this spongy appearance very highly; it is therefore often induced by the addition to one of the wash-waters of sufficient acid to make it contain about 1.5 per cent. of HNO_3 .

The regularity of the changes of shade caused by slight variations in the composition of the precipitants when soluble lead salts are employed disappears completely when insoluble or only slightly soluble compounds are substituted for them, and other substances have to be added and other methods of treatment employed which are incapable of classification. In the manufacture of chrome oranges the variations are much smaller, the yellowness or redness of the shade being strictly dependent on the weak or strong alkalinity of the liquids.

By treatment of chrome yellow with caustic or carbonated alkali they are converted into oranges, which can be made of as red a shade as desired by the employment of a sufficiently concentrated solution, the absolute amount of alkali added not having any relation to the resulting colour. A large number of experiments conducted by the author show that not more than 73.65 per cent. of the lead chromate can be converted into the basic compound in this way without danger of decomposing it entirely, and the process has the further disadvantage of causing the loss of the dissolved chromic acid, as the solutions cannot be economically worked up. For the avoidance of this loss several methods are available, each of which possesses its advantages, yielding an orange specially suitable for one particular process. The simplest is to precipitate a solution of basic acetate of lead with sodium chromate, the proportion between the numbers of molecules of litharge and normal acetate being varied according to the shade required. If this proportion is 1:2, the resulting orange has the formula $Pb_2(OH)_2CrO_4$, being the most basic it is possible to prepare, and therefore the deepest in colour; on increasing the litharge to its maximum (2:2) other compounds are formed, e.g., $\frac{1}{2} PbCrO_4$, $\frac{1}{2} Pb(OH)_2$, together with free caustic soda, which has the valuable property of causing the shade to be very deep and fiery, the decomposition, however, must be conducted at a high temperature ($80^\circ C.$) to avoid the admixture of free lead hydrate which would spoil the colour. It is also possible to reduce the proportion of the litharge below that of 1:2, in which case various oranges may be produced having shades intermediate between the chrome yellow and chrome red; they, however, become more expensive to prepare, inasmuch as more acetic acid passes into the by-products.

From the lemon chromes having the general formula PbCrO_4 , PbSO_4 various shades of chrome orange can be prepared by the action of caustic soda without loss of chromic acid, the less sulphate in the original substance, the yellower being the shade of the resulting orange. The lead sulphate is probably decomposed in the following manner:—

I.

II.

Chrome orange so prepared, though slightly more expensive than that made as before described, possesses an exceptionally fine colour and a high degree of density.

The soluble lead salts may be replaced as a source of chrome yellows by the cheaper insoluble compounds, such as white lead, basic chloride, and also specially prepared sulphate, the ordinary sulphate of commerce being usually too impure for the purpose. The action of the normal or acid chromates on white lead is to produce yellows of such a bad colour as to be useless, but good results are obtained by converting a small quantity of it into either acetate or nitrate by the addition of the respective acid; on the addition of the precipitating mixture the soluble portion is attacked and part of the original acid set free, this action proceeding until the whole of the white lead is converted into chromate. A portion of the liberated acid is neutralised by the alkali of the bichromate, and in the production of pale yellows care must be taken to add in the first place enough acid to combine with the whole of the metal of the chromate employed, lest the shade should be injured by the action of the free alkali. The sulphuric acid used in the precipitation (cf. Table I.) must not be taken into account in this calculation. If the basic chloride of lead is used instead of white lead, the same process is employed. Sulphate of lead prepared from the basic acetate is admirably adapted for the production of certain shades of yellow, but it should not be dried, but employed in the form of a paste, and great care must be taken to keep it in excess during the reaction. Should the shade of the chrome not be dark enough, a small addition of soda should be made to one of the wash-waters.

B.—THE TECHNOLOGY OF CHROME YELLOW MANUFACTURE.

The following formulae for the production of various yellows are given as embodying the considerations mentioned above:

1st. For Soluble Lead Salts:—

	Kilos.
Lead acetate.....	100
Potassium bichromate.....	18
Sulphuric acid (66° B.),.....	12

This mixture yields a yellow of the formula PbCrO_4 , PbSO_4 . To obtain good shades the amount of water employed should not be less than 1,000 litres, or double as much with the nitrate. In the latter case it is better to neutralise the lead nitrate and to replace the acid by the sulphate of an alkali or magnesium, or preferably aluminium; for the neutralisation of the bichromate the best substance is magnesite. The formula thus becomes: lead acetate and bichromate as before; magnesite, 6 kilos.; and aluminium sulphate, 27 kilos.

2nd. *The Basic Acetate Method.*—Litharge, 76 kilos.; acetic acid (30 per cent.), 42; bichromate, 21.5; sulphuric acid, 21.5; water, 2,000 to 3,000 litres. To obtain a denser chrome 10 kilos. of soda should be added to the acetate and 5 of the sulphuric acid replaced by 10 of aluminium sulphate. For the production of an orange chrome the following formula is given: Litharge, 76 kilos.; acetic acid (30 per cent.), 42; bichromate, 24; Solvay's soda, 15; and caustic soda (100 per cent.), 5. Care must be taken that the temperature does not rise sufficiently high to spoil the shade.

3rd. *The White Lead Method.*—In this case the white lead must be in the finest state of subdivision possible and suspended in the water; white lead, 100 kilos.; nitric acid (36 B.), 12; bichromate, 13; and aluminium sulphate, 10; or nitric acid (40° B.), 44; bichromate, 24; sulphate, 20, the latter giving the more fiery shade. For the production of an orange, white lead, 100 kilos.; nitric acid (36 B.), 18; bichromate, 28; and caustic soda, 8, the latter being best added to the bichromate before precipitation, and the temperature kept between 65° and 75° C.

4th. *The Basic Chloride Method.*—The same proportions and temperature are suitable here as in the case of the white lead.

5th. *The Sulphate Method.*—Lead sulphate, 100 kilos.; bichromate, 24—45; Solvay's soda, 8.75—16; ammonia (24 per cent.), 1—2; and acetic acid (30 per cent.), 5—10. The sulphate in the form of a cream being gradually added to the other ingredients after solution.

C.—ZINC CHROMATES.

Although it is possible to prepare lead chromates having shades varying imperceptibly from the palest lemon to a deep granite-red, in the case of the zinc compounds scarcely any variation from the normal is possible, this being, however, different from anything obtainable with lead. Zinc yellows fall considerably below the ordinary chromes in their colouring power, but they are faster in light and are less poisonous. More than 80 per cent. of the amount annually made in Germany is used for the production of zinc green by mixing with Prussian blues, of which substance Holland, Switzerland, and Hungary are the greatest consumers. The zinc yellows met with in commerce vary in their constitution considerably, being usually acid chromates of zinc and potassium; basic zinc chromates being rare. Ordinary salts of zinc invariably contain small amounts of iron, which must be removed before they are used in the manufacture of colours. The simplest method is to heat them with the quantity of permanganate theoretically necessary to convert all the iron present into the ferric state, adding zinc hydrate, which need not be free from iron; after thorough stirring the whole is allowed to settle and filtered, when the liquid will be found not to contain a trace of iron. On the addition of chromate to such solutions a yellow precipitate (ZnCrO_4) falls, but owing to its great solubility in the liquid this process is valueless. By using an excess of bichromate the zinc chromate combines with some of the alkaline salt, forming the compound $(\text{ZnCrO}_4)_2\text{K}(\text{CrO}_4)$, which may be washed without loss, but on drying yields an extremely hard sandy powder, possessing, in spite of its fine colour, no value as a pigment. By neutralising the two solutions before precipitating, a much higher yield of chromate is obtained, but still so much chromic acid is lost as to make the process too expensive to pay; formerly in addition of calcium chloride was made to the neutral solutions so as to precipitate some of the acid as calcium chromate which remained mixed with the zinc salt. The best results, both in regard to yield and colour, are obtained by adding to the zinc salt sufficient alkali to decompose one quarter of it, so that the chrome may have the formula $(\text{ZnCrO}_4)_2\text{ZnO}$; to the bichromate enough alkali should also be added to convert it into the normal salt. It is to be remarked that the nature of the metal combined with the chromic acid has the greatest influence on the shade of the zinc yellow, so much so that in manufacturing "acid" zinc yellow, the use of sodium bichromate is inadmissible. A basic zinc yellow prepared from the sodium salt has a redder and more cloudy shade than one made from the potassium compound, but the difference is hardly noticeable when sodium-potassium chromate is employed.

Modern zinc yellows are invariably prepared from acid solutions, and consist of a double salt of zinc chromate and potassium bichromate, mixed with a varying amount of unchanged zinc oxide, which must not be regarded as an adulteration of the pigment, as its presence gives the substance "body." As previously stated, sodium bichromate is inadmissible, as it does not form similar double salts. The raw material is usually zinc oxide, which is met with

in a state of great purity; by the addition of sulphuric acid this is converted into basic zinc sulphate, potassium bichromate solution is added and the whole stirred vigorously for an hour. At the end of this time the zinc chromate which was previously in a state of partial solution, begins to separate out in the form of a brilliant yellow scum on the surface of the liquid consisting of $(\text{ZnCrO}_4)_2 \cdot \text{K}_2\text{Cr}_2\text{O}_7$, while the solution rapidly becomes almost colourless. Suitable proportions are: zinc oxide, 100 parts; sulphuric acid (66° B.), 60; and potassium bichromate, 100. Although it is hardly possible that any hydration takes place, it is found advisable to soak the zinc oxide in water for 24 hours before the other reagents are added, the sulphuric acid after dilution being added gradually. Great care must be taken that the solutions are all cold and the stirring is continuous to avoid the pigment being deposited in a hard sandy form. Zinc yellows thus prepared are not liable to change during washing in a manner analogous to the lead compounds.

II.—PIGMENTS CONTAINING CHROMIUM OXIDE.

Chromium oxide alone is of no value as a pigment, as useful shades can only be prepared from mercurous chromate or from a mixture of ammonium bichromate and picric acid, both of which processes are far too expensive. Of the various pigments containing chromium oxide by far the best is Guignet's green, an oxyhydrate of chromium of the formula $\text{Cr}_2\text{O}_3(\text{OH})_2$. This being absolutely unchanged by light and being scarcely affected by any chemical action, is much employed for lithography, bank note and calico printing. The process for its manufacture consists in melting together at a low red heat potassium bichromate and boric acid, the resulting chromium borate being decomposed by the action of water into the oxyhydrate. Formerly the fusion was conducted in ordinary reverberatory furnaces, but now muffle are generally employed, in which the temperature is much more easily regulated. Other pigments of this class mostly contain chromium phosphate, the best, having regard to the cost as well as the colour, being Plessy's green. This is prepared by reducing a mixture of bichromate and monocalcium phosphate with sugar. Other pigments of considerable technical interest are the chromium silico phosphates and their double salts with the phosphates of the alkaline earths. Under certain conditions it is possible to prepare from them colours of unsurpassable beauty and purity. They are made by reducing with sugar a mixture of bichromate, silico phosphoric acid and calcium or barium phosphate. By the simple precipitation of chromium salts by solutions of silico phosphates no useful results are obtained. F. H. L.

The Discovery of Ultramarine. J. Heintze. J. prakt. Chem. 43, 98—105.

At the time when Guichard and Guignet were disputing as to the priority of discovery of artificial ultramarine, the chemist to the Royal Porcelain Manufactory of Meissen, Kottig, independently discovered a method of manufacture of that substance. In the spring of 1828, this chemist, whose claims have not been fully recognised, was engaged in an attempt to make a lead free fusible glass, using for this purpose a mixture of sodium silicate and pure clay, and, after strongly heating the same, observed that a blue coloured substance was produced in small amount. He continued his experiments now with the object of discovering a suitable method of manufacturing the blue substance, and found that he could regularly produce it from a mixture of sodium sulphate, silica, chromate, and clay. Subsequently, however, he modified the composition of this mixture and selected soda crystals, kiesel, powdered brimstone, and charcoal, as the best materials. The manufacture of ultramarine at Meissen was abandoned in 1870, but as the quality of the product made there was, in its time, considered superior to most of that made elsewhere, the author gives a detailed account of the method of manufacture followed there.—F. H.

Manganese Sulphide as a Pigment. P. de Clermont and H. Guiot. Bu'l. Soc. Chim. 1891, 5, 480—482.

THE flesh-coloured, hydrated manganese sulphide which is obtained by the addition of ammonium sulphide to a solution of manganese chloride, on standing, or more rapidly on boiling with water, changes colour to green. This green sulphide when washed and dried, yields a powder of the same colour, which is also unstable, being oxidised by mere exposure to air. It is, however, rendered permanent by removing its water of hydration, which is effected by heating it moderately in a current of hydrogen sulphide, carbon dioxide, or ammonia. Thus prepared it is suitable for application in paper staining, printing, &c. —E. H.

Action of Metals, Salts, Acids, and Oxidising Agents on India-Rubber. W. Thomson and F. Lewis. Proc. Manchester Lit. and Phil. Soc. [4] 4, April 1891. (See also this Journal, 1885, 710.)

THE method adopted was to take a fine sheet of india-rubber spread on paper and vulcanised by the cold process with a mixture of chloride of sulphur and carbon bisulphide, and to examine the action on this of the various substances; on breaking the paper the fine sheet of caoutchouc was left free, so that its stretching properties could be examined.

Action of Metals.—The various metals, whose action was studied, were used in the form of filings sprinkled on the rubber. The whole was then kept at a temperature of 60° C. for ten days. Copper was found to have by far the most injurious action. Platinum, palladium, aluminium, and lead have a very slight action, but magnesium, zinc, cadmium, cobalt, nickel, iron, chromium, tin, arsenic, antimony, bismuth, silver, and gold have none.

Action of Metallic Salts and Oxides.—Saturated solutions were made in water and painted on small pieces of the rubber, or in the case of insoluble substances pastes were made with water and painted on, the whole being then allowed to dry. The heating was subsequently carried out as before. The following compounds of copper entirely destroyed the rubber:—Sulphate, chloride, nitrate, ferrocyanide, oxide, sulphide, also arsenic iodide, silver nitrate, strontium chloride, vanadium chloride, manganese oxides, bismuth chloride. The following had an injurious effect:—Ferrous nitrate, sodium nitrate, uranium nitrate, ammonium vanadate. The following had very little action:—Lead chromate, ferrous sulphate, zinc acetate, zinc chloride, tin perchloride; whilst the behaviour of about 60 salts having no action whatever, was examined.

Exceedingly small quantities of copper salts are injurious to rubber, and it was found that wherever the cloth used in making proofed cloths contained even traces of copper, the rubber became gradually hardened and destroyed. With reference to the use of the various blacks the authors point out that manganese oxides should not be present, but they assert that logwood chrome blacks may be used with impunity.

Action of Acids.—Very dilute solutions of hydrochloric, sulphuric, chromic, citric, or tartaric acid are stated not to be prejudicial, but nitric acid rapidly attacks rubber. A solution of sulphuric acid containing about 10 per cent. of H_2SO_4 destroys the properties of the rubber.

Action of Hydrogen Peroxide.—Since ozone rapidly attacks india rubber, and in view of the fact that chromic acid has only slight action, samples of rubber were placed in both acid and alkaline solutions of hydrogen peroxide for a month. Such treatment has no appreciable injurious action.—T. L. B.

The Applications of Gutta-percha. Lagarde. Ann. Télégraphiques, 18, 1891, 5. Proc. Inst. Civil Eng. 105, iii, 93—99.

GUTTA-PERCHA, as found and used, especially in the manufacture of submarine cables, is a combination of several substances. The experiments made by the author and

detailed in this paper were undertaken with the view of ascertaining the influence possessed by each of these substances on the insulating power of the gutta-percha. The substances regarded as pure gutta-percha is accompanied by two resins—fluavile and albane, which exist in varying proportions in the commercial product. The more fibrous a gutta-percha is the better is its quality for most of the purposes for which it is used. Its specific gravity is greater than that of water, but apparently less on account of the air which is enclosed. Pure gutta-percha being insoluble in ether and alcohol, while the accompanying resins are soluble in these liquids, a complete separation of the resins can be effected by boiling the raw material in absolute alcohol. The albane being soluble in boiling alcohol only, advantage is taken of this property to separate it from the fluavile. The mineral constituents of gutta-percha being present in very small proportion—in no case above $\frac{1}{2}$ per cent.—were not specially considered in these experiments. As the result of a series of tests it was found that the greater the proportion of pure gutta-percha in a given sample, the less was its insulating power, and the author therefore recommends that, in specifying the qualities to be possessed by cables insulated with gutta-percha, it is advisable to fix a maximum as well as a minimum of insulation.

Experiments were also made to ascertain the influence of the water contained in gutta-percha on its insulating power. It was found that the power of insulation diminished in proportion to the percentage of water, all other conditions being similar.

Thin sheets of gutta-percha were exposed to air and water respectively for two months, after which time it was found that the proportion of resins had increased at the expense of the pure gutta-percha. When the material contained a large proportion of water in the first instance the change took place more rapidly, and for this reason the author considers that the percentage of water in the gutta-percha insulation of cables should not exceed 5.

In order to test the influence of exposure to the air on the insulation of cables, a length of 1,000 metres (1,093 yards) was tested at intervals of one month, when the insulation was found to be better and the proportion of resins in the gutta-percha greater than at the date of manufacture. It is therefore important that cable-tests should be carried out at a definite interval from the date of manufacture.

As a result of his experiments, the author recommends that, for telegraphic cables with gutta-percha dielectric, the proportion of resins contained in the material used should be specified, and that the proportion of mineral matter should not exceed $\frac{1}{2}$ per cent., and of water 5 per cent. The insulating power of the pure gutta-percha was found to be about three-quarters of that of the commercial substance before the separation of the resins.

PATENTS.

An Improvement in the Manufacture of Ultramarine. R. W. E. McIvor, London. Eng. Pat. 9200, June 13, 1890. 4d.

THE inventor has found the following proportions of raw materials to yield excellent results:—sodium sulphide, 42 lb.; sulphur, 20 lb.; kaolin (China clay), 110 lb.; soda (as carbonate), 106 lb.; or caustic soda, 40 lb. These quantities yield about 2 cwt. of ultramarine blue. The clay and soda are first roasted together at a red heat so as to effect partial double decomposition and the product is ground. "Sulphur liquor" is then made by dissolving flowers of sulphur in a solution of sulphide of sodium to saturation. The ground material is then made into a thick paste with the sulphur liquor, the paste dried in an oven and the dried mass broken into small pieces, is roasted without access of air in a closed earthenware retort first at 250° to 300° C. for an hour, then at a red heat for eight hours, and finally just below dull redness in presence of a slow regulated current of air. The retort must be quite cold before being opened.

—E. G. C.

An Improved Copying Ink. W. S. Conrad, Southsea. Eng. Pat. 10,491, July 5, 1890. 4d.

A SATURATED solution of a deliquescent salt, preferably nitrate of ammonium, is added to a "strong, slowly-drying ink, containing from one-fourth to one-half glycerin, but made without acids."—E. G. C.

A Novel Manufacture of Oil Paint in Sheets, applicable for Rendering Fabrics and other Materials Impermeable to Moisture, or for Decorative and similar Purposes. J. A. Maynard, Paris, France. Eng. Pat. 11,780, July 28, 1890. 6d.

UN-SIZED paper, free from blisters, &c., is coated with an aqueous solution of dextrin. When this coat is dry a layer of oleic oil paint is applied; and the sheet so obtained may be used for packing purposes, to render fabrics impermeable to water, &c.—E. G. C.

A Process for Oxidising and Drying Vegetable Oils and Utilising the same for the Manufacture of Floor Cloth and like Products. F. Walton, London. Eng. Pat. 12,000, July 31, 1890. 4d.

WITH a view to accelerate the oxidation of drying oils the inventor forces air through the oil kept at about 100° F. under a pressure of 5–10 atmospheres. The air and oil are thoroughly mixed by agitators and by perforated plates, through which latter the air is forced. Vapour of turpentine or other oxidising agent may also be mixed with the air. With the gradual solidification of the oil the speed of the agitator is reduced so that the oil is ultimately obtained in a granular condition. To prevent ignition the oil is cooled before being discharged into the open air. If to be mixed with rosins and gums to form cement for the manufacture of linoleum, &c., these substances should be fused before addition of the oil.—K. E. M.

The Application of Certain Waste Materials for the Production of a New or Improved "Mineral White," and Improvements in the Process of Manufacture. J. J. Lee, Manchester. Eng. Pat. 12,085, August 1, 1890. 4d.

WASTE plaster of Paris moulds are scraped, brushed, or scrubbed, broken up into small pieces, subjected to heat if necessary, and then ground to fine powder.—E. G. C.

Improvements in the Manufacture of White Lead and in Apparatus employed in such Manufacture. E. V. Gardner, London. Eng. Pat. 12,414, August 8, 1890. 8d.

IN this process white lead is manufactured from the metal by passing vapour of acetic or nitric acid mixed with aqueous vapour, carbonic acid, or air, over sheets of lead. The action is accelerated, first by maintaining a temperature of 125° F. to 135° F., and secondly by an electric current. This is generated either by a dynamo or by coupling up the lead plates with tin or other material electro-negative to lead. In this latter case the moist vapours act as the electrolyte. The chamber in which the operations take place are glazed and furnished with suitable shutters, thus enabling the progress of the operation to be observed.—V. C.

An Improvement in the Manufacture of Blocks of India-Rubber. "Charles Mackintosh and Company, Limited," and J. Bagnall, Manchester. Eng. Pat. 12,786, August 15, 1890. 6d.

THE blocks of india-rubber from which sheets are cut ordinarily contain included air bubbles, which, when the sheets are cut, causes holes and perforations, which sometimes necessitate the removal of portions of the sheet, thereby causing much waste. This invention claims to get rid of the difficulty by exhaling the air from the cylinder in which the plastic rubber is placed before subjecting it to the pressure of the hydraulic ram.—V. C.

Improvements in the Manufacture of India-Rubber Threads. "Charles Mackintosh and Company, Limited," and J. Bagnall, Manchester. Eng. Pat. 12,787, August 15, 1890. 4d.

The improvement consists in the method of preparing the sheets from which the threads are cut, the actual process of cutting being the same as that ordinarily employed. In the usual method of forming the sheets the rubber is spread in the plastic state with naphtha or rolled in a calendar with or without naphtha. Either process, or combination of the two, alike diminishes the strength of the rubber; and likewise fails to give sheets of uniform thickness. In the new process the sheets are cut from a cylindrical block, the sheets are then vulcanised and afterwards wound on a roller, being then cut into threads in the ordinary manner.—V. C.

Improvements relating to the Manufacture of Carbonate of Lead and to Apparatus therefor. S. K. Morris, London. Eng. Pat. 15,903, October 7, 1890. 11d.

LEAD is reduced to fine shreds or strips by being melted, and then caused to drop through holes or apertures in a die or block into a tank of water. The shreds or strips are then subjected to the action of steam, acetic acid and carbon dioxide, the last-named being produced by the combustion of refined petroleum or some other suitable hydrocarbon.—I. G. C.

Improved Preparation for Use as a Substitute for Linseed Oil in the Mixing of Pigments. J. L. A. Bokelund, Gothenburg, Sweden. Eng. Pat. 5870, April 6, 1891. 4d.

This preparation consists of a mixture of rosin oil, refined mineral oil, and methylated spirit.—I. G. C.

An Improved Liquid Preparation for the Protection of Bright or Polished or Unpolished Metallic Surfaces, and which may also be used as an Anti-Fouling and Anti-Corrosive Composition. T. Maxwell, Glasgow. Eng. Pat. 6916, April 22, 1891. 4d.

The following ingredients and proportions are used.—Rosin, about 16 parts; naphtha, turpentine, or light mineral oil, about 16 parts; and boiled or raw linseed or other oxidisable oil, about 2 parts.—I. G. C.

The Manufacture and Production of Hydrocarbon Products or Compositions for Use for Insulating or other Purposes. J. A. Johnson, London. From J. Wen, New York, U.S.A. Eng. Pat. 8573, May 12, 1891. 8d.

The patent relates to the production of a substance termed "litho carbon," from a natural material occurring in sand or shell rock in Texas. Litho carbon appears to be a polymeric terpene, having the empirical formula, $C_{10}H_{16}$. It is a black, tough, flexible, solid, and somewhat plastic at ordinary temperatures. Combined with sulphur the compound serves for insulating purposes; amalgamated with india-rubber it can be used for waterproofing; in suitable solvents, as turpentine, it forms a pigment; and the material by itself will serve for a lining for tanks and the like, for holding acids.

It is prepared as follows.—The broken rock containing the crude material is placed in a tank, through which the vapour of naphtha is caused to pass, dissolving out the crude hydrocarbon. Superheated steam or hot air is then passed through the naphtha solution of the crude hydrocarbon, whereby the naphtha distils off together with a 25 to 30 per cent. of a volatile sulphur-containing oil. The purified hydrocarbon which remains behind contains a small quantity of oxygen, which combines with it during the process, and the presence of which appears to be essential to its toughness and elasticity. The removal of the volatile oil endow the material with its drying quality, which the raw product does not possess.—V. C.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

Preliminary Note on the Technical Analysis of Gambier. H. R. Procter.

See pages 681—683.

PATENTS.

Improved Substitutes for Tannin. S. Thorn, Cleckheaton. Eng. Pat. 10,706, July 10, 1890. 4d.

THE inventor substitutes "in place of this operation of inserting tannin" or other article used at present to effect the same purpose, the following operations:—The hide is treated in a bath containing 3 lb. of alum, 4 lb. of salt, and water, in suitable proportion. After drying and scouring, the "raw hide" is placed in a bath prepared from 1 lb. of dry allumen, 6 lb. of oil, and "water as required," for a length of time varying according to the weight of the hide. The hide is then dried in the usual way.—B. H.

Improvements in the Treatment of Skins and Hides. C. S. Hull and P. S. Burns, Boston, Mass., U.S.A. Eng. Pat. 8096, May 12, 1891. 4d.

THIS invention is for the use of the sulphonic acids of naphthalene (α - and β -mono- and disulphonic acids) for the purpose of neutralising the alkali employed for unlairing. A solution containing 2 to 5 per cent. of the acids is best employed and the skins or hides are subjected to the action of the acid solution for a length of time dependent on the kind of skin under treatment. As the naphthalene sulphonic acids also act as a preservative, the skins after treatment are not only freed from alkali, but may be considered "pickled" and may be transported in this condition and the tanning performed in another place.—B. H.

XV.—MANURES, Etc.

Humus. Berthelot and G. André. Compt. Rend. 112, 916—922.

AS a preliminary to the investigation of the humus of the soil the authors have made researches in the ulmin and ulmic acid produced from sugar. The account of the most important experiments and of the results form the subject of the present communication.

1,500 grms. of cane sugar in aqueous solution, boiled with pure concentrated hydrochloric acid, yielded after prolonged washing with boiling water 236 grms. of ulmic matter. The composition of this matter varies with the intensity of the action of the hydrochloric acid, but it retains neither ash nor chlorine, in one case it contained per cent. C, 66.41; H, 4.57; O, 29.02, corresponding to $C_{10}H_{14}O_{12}$, in another sample the percentage composition was C, 63.91; H, 4.58; O, 31.51, corresponding to $C_{10}H_{16}O_{11}$. In contact with water this substance behaves like a colloid, swelling up and ultimately becoming gelatinous. In contact with alkalis, potash, soda, baryte, or lime, even when extremely dilute it undergoes hydrolysis, takes up alkali from the water forming insoluble salts which offer great resistance to the action of water, more especially in the cold, but are nevertheless gradually dissociated by it. Dilute hydrochloric or sulphuric acid

decomposes them immediately and yields the acid, which becomes more hydrated the longer the contact with the alkali has been, ultimately becoming soluble in a manner similar to levulinic and such like acids. With dilute ammonia (3·3 per cent.) in the cold, or very dilute (0·33 per cent.) at 100° in sealed tubes, the ulmic matter absorbs about 4 molecules of ammonia producing a gelatinous insoluble matter, which loses ammonia during the washing and drying operations, but yet after boiling with water and magnesia retains a proportion corresponding with the composition $C_{75}H_{33}NO_{26}$ which would be that of an amido acid formed from two molecules of the ulmic matter. A larger quantity of nitrogen is absorbed from the 3·3 per cent. ammonia in sealed tubes at 100°.

The potassium compounds serve for an example of the action of alkalis, when the ulmic matter is exposed for four days in excess of dilute potash, an insoluble compound of the composition $C_{36}H_{13}K_3O_{11}nAq$ is obtained, which after prolonged washing with cold water yields a soluble basic compound of the approximate composition $C_{36}H_{16}K_6O_{14}nAq$ and an insoluble compound $C_{36}H_{15}KO_{14}$ (apparently identical with Malaguti's ulmine, he overlooked the potash) which is scarcely attacked by carbonic anhydride in the cold but is decomposed at once by hydrochloric acid, yielding the acid $C_{36}H_{15}O_{14}$. The original ulmic matter is, however, capable of decomposing, to a very small extent, a solution of potassium chloride with the liberation of hydrochloric acid.

From these results the authors are inclined to regard the ulmic matter obtained by the action of hydrochloric acid on sugar as a condensed anhydride or a mixture of several anhydrides derived from certain acids resulting from the transformation of the sugar.—D. A. L.

Treatment of Vines attacked by Phylloxera with Carbon Disulphide mixed with Vaseline. P. Cazeneuve. Compt. Rend. **112**, 971—974.

THE introduction of American plants to replace those destroyed by parasites in French vineyards has not arrested the use of insecticides for the protection of French vines still attacked by *Phylloxera*, and for this purpose carbon bisulphide (either pure or dissolved in water), sulpho-carbonates, and submersion continue to be employed with more or less success, the carbon bisulphide is by far the more efficient, but is too volatile and does not diffuse with sufficient rapidity. When, however, it is mixed with vaselin, its volatility is reduced and its diffusibility is increased, the former proving advantageous in light and calcareous soils the latter in heavy soils, in accordance with theoretical considerations. The vaselined sulphide is applied in the same way as the ordinary sulphide, depositing some at the foot of the vine stock and spreading the rest over the surface; this treatment is found to be effectual, with it *Phylloxera* is no longer seen in the roots, vegetation is luxuriant, and numerous new rootlets indicate a decisive increase in vitality; the manuring on a test tract of land had not been altered for six years, therefore the improvement was solely due to the insecticide.—D. A. L.

Nitrogenous Constituents of Soils. Berthelot and André. Bull. Soc. Chim. 1891, **5**, 643—646.

IT has been previously established (Ann. Chim. Phys. **9**, 289), that ordinary soil contains no appreciable quantity of free ammonia or ammonium salts, but amido-compounds, the slow decomposition of which by acids and by alkalis, and even by pure water at the ordinary temperature, gives rise to the ammonia found on analysis; this same decomposition brought about by water and by carbonates of the alkalis and alkaline earths, gives rise also to the ammonia, which is emitted by soils at the ordinary temperature and diffused into the atmosphere.

The amido-compounds which thus undergo decomposition are either true amides, or compounds, derived from fixed or

volatile nitrogenous bases, some of which are soluble, some insoluble in water; the decomposition of these insoluble nitrogenous compounds by acids or by alkalis may give either soluble or insoluble products.

Quantitative experiments on the decomposition of the amido-compounds present in soils, under the influence of potash and hydrochloric acid, lead to the conclusion that those amido-compounds which are decomposed by cold concentrated potash, belong to two distinct groups, which are acted on at very different rates. It has also been found that the insoluble amido-compounds are decomposed by dilute acids even more quickly than by dilute alkalis. By the prolonged action of dilute alkalis the proportion of nitrogenous compounds insoluble in potash is increased, but at the same time the percentage of nitrogen which they contain is diminished. The action of alkalis at 100° and continued for 26 hours, renders soluble 93·6 per cent. of the organic nitrogen originally present in the soil; under the successive influence of alkalis and acids 95·5 per cent. of the organic nitrogen is rendered soluble.

These results indicate in what manner the insoluble nitrogen of the humic constituents of the soil may be gradually rendered available, the action of the weak acids and alkalis present in the soil being similar to that of the more energetic reagents employed in these experiments, but requiring, naturally, a longer time to produce an equal effect.—F. S. K.

Disposal and Utilisation of Fecal Matters. L. Ketjen. Zeits. f. angew. Chem. 1891, 294—295.

See under XVIII. B., page 721.

Nitrification. Part IV. R. Warrington. Proc. Chem. Soc. 1891 [98], 92—91.

THE first section of the paper describes early experiments, made in 1878—81, showing the existence of an agent producing only nitrites, and the means of separating it from soil. It was at first thought that the age of the culture was the factor which determined the loss of the power of producing nitrates, but this idea was negatived by subsequent experiments. Successive cultivation in ammoniacal solutions, made permanently alkaline with disodium carbonate, was found to be a certain method of obtaining a purely nitrous agent. Pasture soil yielded the nitrous agent more readily than arable soil.

The isolation and properties of the nitrous organism are next described. The gelatinous matter which appears under certain conditions at the bottom of the old cultures was in 1883 examined microscopically, and found to consist of circular corpuscles imbedded in a zooglia. In 1886 this jelly was spread on gelatine, but it yielded no nitrifying organism. In 1889 a systematic attempt at the isolation of the organism commenced. Successive cultivations were made in an ammonium carbonate solution, supplied with phosphates, &c., but containing no organic matter. A series of transparent cultures was obtained, containing only nitrites. These cultures were spread on gelatine and Agar-agar, the composition of the jelly being made to correspond, as far as possible, with that of a nitrifiable solution. The later cultures yielded on gelatine one organism only, a short bacillus. This and all the other organisms obtained by cultivation on gelatine from nitrified solutions were seeded into both liquid and solid media susceptible of nitrification, but without result. Microscopical examination of the nitrified solutions showed that cocci were abundantly present, but these never appeared on the gelatine cultures.

The first attempts to separate the nitrous organism by the dilution method failed. By substituting an ammonium chloride solution with calcium carbonate for the ammonium carbonate, success was attained in October 1890, three nitrified cultures seeded with dilutions of 1:10,000, 1:100,000, and 1:1,000,000 giving no growth on gelatine.

The nitrous organism thus obtained oxidises ammonia to nitrous acid and has no effect on nitrites. It produces nitrous acid in solutions of asparagine, milk, urine, and urea. Grown in broth containing calcium nitrate, it does not reduce the nitrate to nitrite. It produces no turbidity or visible change when grown in broth or in any of the other solutions named.

The nitrous organism requires no organic matter for its nutrition; it is apparently capable of assimilating carbon from acid carbonates. The presence of either calcium or sodium acid carbonate distinctly favours nitrification; neutral sodium carbonate greatly hinders nitrification. The proof that carbon is assimilated from carbonates has been furnished by Winogradsky. The energy that is required for the decomposition of a carbonate is apparently furnished by the oxidation of ammonia on nitrogenous organic matter. Calcium acetate (0.25 gram. per litre) favours nitrification when only the nitrous organism is present.

The nitrous organism occurs as nearly circular corpuscles, varying from minute points up to nearly $1.0\ \mu$ in diameter; these circular organisms stain deeply. It also occurs as oval cocci, the length frequently exceeding $1.0\ \mu$, the ends occasionally more or less truncated.

The remainder of the paper deals with the nitric organism. Results obtained in 1880-81 revealed the existence of an organism which energetically converted nitrites into nitrates, but was apparently unable to oxidise ammonia. In 1886 and 1890 attempts were made to separate the active organism from the 1881 cultures by growths on gelatine and potato; none of the organisms thus separated had any power of oxidising either ammonia or nitrites. Recent results show that the nitric organism develops freely in inorganic solutions containing potassium nitrite, phosphates, &c., especially if supercarbonates are present. Mono-sodium carbonate, 1-4 grms. per litre, exerted a very favourable influence, 6 grms. a retarding influence. Di-sodium carbonate greatly hinders its action.

The nitric organism produces neither nitrites nor nitrates in ammoniacal solutions, even when carbonic acid, or mono-sodium carbonate, or calcium acetate is supplied. In the absence of ammonia it energetically converts nitrites into nitrates; the presence of ammonia is apparently a great hindrance to its action.

An attempt to isolate the nitric organism by the dilution method failed, but apparently only one other organism (a stout bacillus growing on gelatine) was present in some of the cultures obtained. The stained preparations from these cultures contained an abundance of the minute circular organisms observed in pure cultures of the nitrous organism; the form of the two organisms is thus apparently similar.

The nitrification performed by soil thus appears to be the work of two organisms, one of which oxidises ammonia to nitrite, while the other oxidises nitrite to nitrate. The first organism is easily separated from the second by successive cultivations in solution of ammonium carbonate. The second is (probably) separated as easily from the first by successive cultivations in solution of potassium nitrate containing mono-sodium carbonate.

The paper was illustrated by photo-micrographs, showing the nitrous organism as developed in ammoniacal solutions, milk, and broth; and the nitric organism grown in a solution of nitrite.

XVI.—SUGAR, STARCH, GUM, Etc.

See under XXIII., page 727.

Derivatives of Xylose. G. Bertrand. Bull. Soc. Chim. **1891**, **5**, 554-557.

The author prepares xylose in the following manner:—Oat straw is first macerated twice with lukewarm water, then boiled for some hours with 10 times its weight of water containing 1 or 2 per cent. of sulphuric acid and ultimately pressed. The liquor obtained from the last operation after separation of the sulphuric acid with baryta is kept slightly acid, and is concentrated on a water-bath; it is then extracted with alcohol, and on evaporating the alcohol from the extract a yellow syrup is left, which sets to a solid mass within 48 hours, after crystallisation has been started with a crystal of xylose. The mass is dried and is purified by crystallisation from 95 per cent. alcohol, the yields varying with the original material employed; thus wheat straw yielded 2 per cent. whilst oat straw gave 4 per cent. of xylose. This glucose is derived from the matter incrusting the walls of cells and serving to consolidate them. By treating xylose with sodium amalgam in an alkaline medium a syrup is obtained, which on agitation with 1 part of 50 per cent. sulphuric acid and 1 part of benzoic aldehyde, yields a precipitate, and the latter, after washing with water and alcohol and dissolving in boiling methyl alcohol is deposited in white gelatinous flocks, they lose benzoic aldehyde on drying, but give analytical numbers approximating to xylose di-benzoic acetal $C_5H_8O_5 \cdot CH(C_6H_5)_2$. This substance resembles the corresponding sorbitol compound in its allotropisms, its solubilities and its behaviour with reagents and by decomposition with dilute sulphuric acid yields xylitol which has not been crystallised. It is, however, slightly dextrogyrate, a 10 per cent. solution giving $[\alpha]_D = 0^\circ 50'$ at 12° , and when nearly dried in a vacuum and heated with excess of acetic anhydride in presence of fused zinc chloride it yields a penta-acetate, but it could not be made to combine with ethylic aldehyde. Xylose forms double salts with cadmium chloride or bromide, 1 part of xylose dissolved in 5 parts of water is agitated with 1 part of bromine until the latter is dissolved; after 24 hours the excess of bromine is boiled off, the liquid saturated with cadmium carbonate, filtered and mixed with an equal volume of alcohol, an abundant crystalline precipitate of cadmium xylonobromide $(C_5H_8O_5)_2 \cdot Cd \cdot CdBr_2 + 2 H_2O$ immediately forms. To obtain the corresponding xylonochloride, which also crystallises with 2 mols. H_2O , the hydrobromic acid formed in the above operation is estimated and removed by means of lead carbonate, an impure solution of xylonic acid remains, which is saturated with cadmium carbonate, cadmium chloride is added and the treatment continued as in the case of the xylonobromide. This reaction of xylose is very sensitive, inasmuch as these salts may be obtained with a few milligrammes of the sugar, and it moreover serves to distinguish xylose from arabinose another point of difference between these two sugars, being the non-formation of a benzoic acetal in the case of the latter sugar.—D. A. L.

XVII.—BREWING, WINES, SPIRITS, Etc.

*On the Fermentation of Starch by the Butyric Ferment.*A. Villiers. *Compt. Rend.* **112**, 536—538.

The author has already shown that the principal products of the action of *Bacillus amylobacter* on starch is dextrin (*Compt. Rend.* **112**, 435; this Journal, 1891, 174.)

There is formed at the same time about 0.3 per cent. of a carbohydrate, which separates from the alcohol that has been used to precipitate the dextrans. It dissolves in a fairly large quantity of warm water, and on cooling the solution deposits fine crystals having a composition corresponding to the formula $C_{12}H_{20}O_{10} \cdot 3 H_2O$. The crystals have a slightly sweet taste, they are but slightly soluble in cold water, and the solution is dextro-rotatory, having $[\alpha]_D = +159.4$. It is unfermentable and does not reduce Fehling's solution, and forms no compound with phenylhydrazine. When warmed with dilute mineral acids it is hydrolysed to dextrose.

A second product of the fermentation of starch by the above-mentioned bacteria is a white amorphous flocculent precipitate; it has the composition of cellulose and is transformed into glucose when heated with dilute mineral acids.—A. L. S.

On the Origin of the Higher Alcohols contained in Fermented Liquors. L. Lindet. *Compt. Rend.* **112**, 663—666.

Two solutions of cane sugar and two solutions of a commercial brewing sugar were prepared. One of each sugar was fermented with a small quantity of yeast, and one of each with a large quantity. The cane sugar solution seeded with the large quantity of yeast yielded an alcohol containing 1.47 cc. of higher alcohol per 1,000 cc. ethyl alcohol. The cane sugar solution seeded with the small quantity gave 2.30 cc. of high alcohols per 1,000 cc. of ethyl alcohol. With the other sugar the corresponding numbers were respectively 3.96 cc. and 5.29 cc.

Two solutions of sugar were fermented under exactly the same conditions except that to one some sterilised brewers' grains were added, which causes the fermentation to go quicker, and in this case the amount of higher alcohols produced was less, the numbers being with grains 4.70 cc., and without grains, 5.29 cc. per 1,000 cc. ethyl alcohol. It was also found that if the fermentation takes place at a high temperature more higher alcohols are produced. At 25° — 27° C., 5.9 cc.; at 18° — 21° C., 5.4 cc.; at 8° — 10° C., 5.2 cc. of high alcohol for 1,000 cc. ethyl alcohol are produced. These experiments show that the higher alcohols are not produced by yeast, but are formed by some other organism present as an impurity.—A. L. S.

On the Use of Liquid Carbonic Acid for the Rapid Filtration and Sterilisation of Organic Liquids. A. d'Arsonval. *Compt. Rend.* **112**, 667—669.

The liquid to be sterilised and filtered is placed in a steel or copper tube to the end of which is fixed an unglazed porcelain tube closed at one end. The upper portion of the steel or copper tube is placed in communication with a bottle of liquid carbonic acid. The pressure of the gas forces the liquid through the walls of the porcelain tube, owing to the great pressure all the colloidal bodies pass through in the solution, and only the living organisms remain behind.

—A. L. S.

The Influence exerted by Various Neutral Potassium Salts on the Solubility of Potassium Bitartrate. C. Blarez. *Compt. Rend.* **112**, 808—811.

In a former paper (this Journal, 1891, 488) the author gives two formulæ representing the solubility of potassium

bitartrate in solutions of potassium chloride. One of these, slightly modified, is given below:—

$$Q\phi = 0.05 + 0.000005 \phi^3 \\ \sqrt{K}$$

in which ϕ = temperature in degrees Centigrade. K = Weight of potassium contained in the potassium chloride.

The author finds that the influence of other potassium salts on the solubility of potassium bitartrate may be represented by the same formula. In other words the nature of the electro-negative element combined with the potassium appears to be immaterial. This fact is well shown by the experimental results embodied in the following table:—

WITH POTASSIUM BROMIDE.

In these experiments the saline solution was agitated for 48 hours at a constant temperature with an excess of powdered cream of tartar.

It is evident from these results that the same influence is exerted on the solubility of potassium bitartrate by quantities of various potassium salts proportionate to their respective molecular weights. In a future paper the author hopes to show that similar laws govern the solubility of other salts in admixture.—H. T. P.

The Properties of Fig Wine. P. Carles. *Compt. Rend.* **112**, 811—812.

Figs are largely employed, especially in Algeria, for the production of fictitious wine. For this purpose figs from Asia Minor are preferred on account of their relative cheapness and richness in sugar. When the fruit is treated with a suitable quantity of tepid water, acidified with tartaric acid, fermentation rapidly commences, resulting in the production of a vinous liquid of about 8° alcoholic strength, and so inexpensive that it defies all competition of genuine grape wine, Algerian or otherwise. Fig wine cannot be distinguished either by taste or the ordinary methods of analysis from genuine grape wine, especially when it is mixed with a proportion of the latter. The detection of fig wine is, however, rendered comparatively easy by the fact that it contains mannitol. In order to separate the mannitol, 100 cc. of fig wine are evaporated to a syrup which is allowed to stand in a cool place for 24 hours. At the end of this time the residue will have solidified, well defined groups of crystals being formed. The crystals are washed with cold alcohol of 85 per cent. strength in order to remove impurities. The residue is mixed with animal charcoal and extracted with boiling 85 per cent. alcohol and filtered. The alcoholic solution yields on evaporation

a crystalline mass of mannitol which may be recognised by its physical and chemical properties. Certain white wines from the Gironde district, as well as raisin and some other wines, contain mannitol, but only to the extent of a few decigrammes per litre; whilst fig wine contains from 6 to 8 grms. per litre. By a determination of the mannitol it is possible to detect an adulteration of normal Algerian wine with one-half or even one-fourth of fig wine.—H. T. P.

The Progress of Purification during the Rectification of Alcohol. E. Mohler. *Compt. Rend.* **112**, 815—818.

THE author has separately collected and analysed the various fractions obtained during the rectification of raw spirit from molasses. A quantity of spirit was distilled, corresponding to 100 hectolitres of alcohol of 100 per cent. strength. Before rectification the spirit was neutralised with soda and diluted to 300 hectolitres. The rectification required 53 hours for its completion, being effected in a Savalle rectifier. Seven different fractions were collected, about two litres of each being taken for analysis. The results, which are expressed in grms. per hectolitre of 100 per cent. alcohol, are given in the following table:—

	Composition in Grms. per Hectolitre of Alcohol at 100 per Cent. of the different Qualities formed during Rectification of Raw Spirit from Molasses.							Composition in Grms. per Hectolitre of the Raw Spirit, and of the Residual Liquid left in the Retort.	
	First Runnings, Worst Portion.	First Runnings, Middle Portion.	First Runnings, Best Portion.	Fine Spirit	Tailings, Best Portion.	Tailings, Middle Portion.	Tailings, Worst Portion.	Raw Spirit.	Liquid left in the Retort.
Acids (as acetic acid)	7.20	3.00	3.00	1.80	1.80	2.10	6.00	121.00	59.56
Ethers (as ethyl acetate)	267.5	79.2	13.2	5.20	8.80	13.60	70.40	59.0	16.63
Aldehydes (as ethyl aldehyde) ..	163.2	111.0	2.4	Very slight trace.	0	Trace	8.00	21.6	..
Furfural	0	0	0	0	Trace	0.60	6.60	0.15	..
Superior alcohols (as amyl alcohol) ..	0	0	0	0	2.58	2500.00	3000.00	337.00	..

Total impurities per hectolitre ..	738.425	226.56	18.72	7.68	13.34	2516.82	9092.55	542.29	76.39
Volume in hectolitres, at each equality of spirit ..	1.93	8.55	24.20	28.02	27.84	5.52	1.91	97.97	200.00
Total impurities	1233.63	1937.08	453.62	200.70	369.38	13892.84	17366.77	53128.15	15278.00
Impurities contained in the whole distillate							53128.15		
Impurities left in the liquid in the retort							50605.46		
Total							2432.69		
							Loss and errors of analysis		

It will be seen that 80 per cent. of the alcohol submitted to distillation is obtained almost perfectly pure, containing only 70 to 180 mgrms. of impurity per litre.—H. T. P.

On the Nitrogenous Constituents of Barley and Malt. W. J. Sykes. *Trans. Inst. Brewing*, **4**, 173—187.

THE albuminoids present in barley and malt are albumen, globulin, albumose, peptone, and gluten; other nitrogenous bodies present are enzymes, amides, and ammonium salts. Albumen and globulin are soluble in cold water, but are precipitated when their solutions are heated, the former at 160° F. and the latter at 110° F. This does not take place when some salts, such as sodium chloride, are present. The globulin of barley emulsion is precipitated if its solution be saturated with sodium chloride.

Albumose is soluble in water, and its solution is not precipitated by boiling, but if saturated with ammonium sulphate almost the whole of it is thrown out.

Peptone is soluble in hot and cold water, and diffusible. It is precipitated from its solution by phosphotungstic acid or tannin.

The gluteins are insoluble in water, but are soluble in slightly acid solutions, such as wort. Their solutions are slowly coagulated on boiling. They have the curious property of being slightly soluble in alcohol. Their presence in wort is shown by carefully neutralising, when a precipitate is thrown out, most of which dissolves in excess of alkali. Ritthausen gives the amounts present in barley as:—Gluten-caseine, 1.27 per cent.; gluten fibrine and mucilage, 1.7 per cent. On drying the precipitate obtained by saturating wort with ammonium sulphate a portion always becomes insoluble; this the author considers to be the gluten present. By making use of the above-described properties, a rough separation and estimation of the amounts of albuminoids present in wort and beer may be made. The only one present to any extent in beer is albumose, and this is unable to supply nitrogenous food to yeast. The best

known of the amides present is asparagine; no determination of the amounts of these bodies in wort or beer have been made; they probably form the chief nitrogenous food of the yeast.

Hilger gives the amount of ammonium salt present in barley as 0.0169 per cent., and in malt 0.0057 per cent.

The nitrogenous constituents of barley and malt may be considered to be:—

	Barley.	Malt.
Total albumen.....	10.54	9.68
Total soluble albumen	2.23	4.05
Albumen precipitated on boiling.....	0.79	0.70
Albumose.....	0.55	1.11
Amide.....	6.98	2.24

Manufacture of Beer from Maize.

THE Handels Museum of July 2nd states that a new brewery product, namely, beer made from maize, is being manufactured and consumed in increasing quantities in France. The cost of production is said to be much below that of beer made from barley, notwithstanding that the beer itself is in no way inferior to the latter. The new beverage is not the result of any improved process, but is made by malting maize, of which it is a pure product, and not (as is done in some districts) the result of mixing maize meal with the worts of barley malt. Owing to the high price of malt, brewers have for a long time been driven to use unmalted cereals for brewing purposes. Experiments have been made with wheat, maize, rice, potato meal, maize syrup, &c.; in such cases there was an insufficient development of the saccharin principle, and, owing to a lack of soluble nitrogenous bodies fermentation did not proceed satisfactorily. Hence the beer became spoiled by a second fermentation, and further, there was a lack of albuminous matter and phosphates which constitute the nutritive properties of beer. These defects are all said to be remedied by using maize malt.

PATENTS.

An Improved Method of Preparing Peptonised Soluble Meat and Peptone. N. Etienne and A. Delhaye, Angrean, Belgium. Eng. Pat. 10,961, July 14, 1890. 6d.

THE meat after removal of the tendons and grease is chopped and mashed, and then mixed with about half its weight of water and heated by steam under pressure at a temperature above 150° C. and under 175° C. for one hour. Part of the albuminoid matter is transformed into propeptone and peptone, which go into solution with the extractive part of the meat. The mass is expressed and a friable residue remains equal to about one-third the weight of the fresh meat used. This residue is treated on the water-bath with an equal weight of concentrated hydrochloric acid until the fibro-muscular tissue is quite disintegrated and decomposed, and the product is filtered. The residue now remaining is sold as manure. The liquors obtained are neutralised with carbonate of soda and then contain peptone and sodium chloride in solution. If pure peptone is desired the liquid is decolourised by animal charcoal and dialysed to remove the salts in solution. If only a meat extract is required the liquors from the squeezing of the meat after treatment with water as above described and the neutralised liquor from the acid treatment are mixed and evaporated in a vacuum until sufficiently concentrated. Modifications of the process are described.—H. S. P.

Improvements in Sterilising Milk and other Substances. W. Budenberg, Dortmund, Germany. Eng. Pat. 20,640, December 17, 1890. 8d.

THE substance is sterilised by heating once or more often in a chamber filled with steam at 100—105° C., after being introduced into bottles fitted with ground stoppers of peculiar construction. One or more holes or grooves are made in the neck of the bottle, and corresponding holes or grooves are made in the stopper in such a way that, by turning the stopper, communication may be made or closed at will between the interior of the bottle and the outer air. During the process of sterilisation, communication between the interior and the exterior is left open, but the upper part of the hole or groove is filled with wadding. No risk of breaking through increased pressure is therefore incurred, as in the usual process of sterilising in hermetically sealed bottles. When the disinfecting chamber is opened and the bottles are allowed to cool, the air enters through the holes or grooves, but the band or plug of wadding stops all micro-organisms. When the contents are quite cold, the stopper is turned so as to close the communication with the outer air, the wadding is removed, and the bottles are ready for transport.

With "saddle-shaped" forms of stopper, the bottle may be used as a feeding-bottle for infants.—P. J. H.

Improvements in Centrifugal Apparatus for Testing the Composition of Milk and other Compound Fluids. S. C. Hauberg, Copenhagen, Denmark. Eng. Pat. 5175, March 23, 1891. 6d.

THE improvement consists in a mechanical device for rotating the disc in which the testing bottles are held. There is a hemispherical depression in the centre of the rotating disc or table which allows it to be fitted horizontally upon the top of an upright shaft or spindle. The top of

the shaft is hemispherical and fits into the hollow in the disc. The shaft is rotated by a belt, and the table fitted upon the top of it then rotates by friction. A drawing of the apparatus is given.—H. S. P.

(B.)—SANITARY CHEMISTRY.

The Pollution and Self-Purification of Streams. J. P. Stearns. Rep. of the State Board of Health of Massachusetts, U.S., 783; Proc. Inst. Civil Eng. Abstracts, **105**, iii, 9—11.

The author examines various sewage-polluted watercourses, rendered foul by the populations of townships on their banks. In these the amount of free ammonia varies from 0.02 to 0.216 parts per 100,000, while he states that several instances could be enumerated where streams containing from 0.01 to 0.03 part of free ammonia per 100,000 parts, were found to be free from offensive odours. To keep within safe limits it is assumed that volumes of from 2.5 to 7.0 cub. ft. of water per second per 1,000 persons, and containing free ammonia, from 0.1116 to 0.0329 part per 100,000 should be regarded as doubtful. With smaller volumes of water the pollution is so great as to be inadmissible; with larger volumes the dilution is such, from the standpoint of offensiveness, as to be clearly admissible. If certain manufacturing uses are to have weight, it might be expedient to insist upon even greater dilution than this. From the standpoint of domestic supply it cannot, so far as is at present known, be pronounced that any degree of dilution will render sewage-polluted water entirely safe.

Upon the question of self-purification, a most important one, when the water has to be used subsequently for drinking purposes, the author insists upon the need of bacteriological as well as chemical investigation. From the analyses of the Blackstone River, Massachusetts, at three different points, the author concludes that between the townships of Worcester and Uxbridge, a flow of 16 miles, the quantity of albuminoid ammonia was reduced by rather more than one half, viz., from 826 to 306 lb. The proportions present of other constituents are discussed, and the state of things prevalent in other polluted streams is examined. The author remarks that while the rapid decrease in the amount of free ammonia below the cities mentioned points to the self-purifying power of rivers, no indication is afforded whether there is a similar decrease in the number of disease-germs. Moreover, it cannot be ascertained that there is any corresponding destruction of the organic matter which the sewage brings into the stream.

The Filtration of Water through Filters of Calined Infusorial Earth. H. Nordmeyer. Zeits. für Hygiene, **10**, 1891, 345; Proc. Inst. Civil Eng. Abstracts, **105**, iii, 13—14.

Attention is directed by the author to a filter composed of a hollow cylinder formed of calined fossil-meal, or diatomaceous earth. The manufacture of these cylinders was at first attended with considerable difficulties, but these have now been overcome. The extreme brittleness of the calined material also offers certain objections to its use, but Berkefeld has overcome all obstacles and has produced the requisite hollow cylinders, closed at one end, from selected specially prepared fossil-meal.

The specific gravity of the denser cylinders is 0.90, but a very porous variety, which can also be made, has a specific gravity of only 0.72. Exclusive of pores the specific gravity is 2.1, so that it may be assumed that the cavities occupy 65.7 per cent. of the bulk. It is found on microscopic examination of a very thin section that these pores are extremely minute, and they are filled with very fine spicules, which cross one another in every direction and form a sort of delicate internal network. The substance is such a very bad conductor that it must not be exposed too suddenly to heat, and it may best be sterilised by being placed in cold water and raised to the boiling point for three-quarters of an hour. Several series of experiment with

liquids containing micro-organisms, which were carried out by the author, are detailed, the results being given in a tabular form. The parts of the apparatus and its construction are described by reference to a diagram. The filter is fitted up with rotatory brushes to cleanse the exterior surface of the cylinder from time to time, when it is being used for very foul liquids. The author states that the filter yields a reliable filtrate, free from germs for a lengthy period, that the germs then found are those of saprophytes, which have grown through the filter, and these may be reduced to a minimum by vigorous rinsings. It will yield a volume of two litres of water per minute, or an amount of filtered liquid far in excess of other domestic filters producing a filtrate free from germs. By mechanical cleansing it can always be restored to its original working condition, and it is thus capable of being used for very turbid liquids.

On the Success Attained by various Systems of Clarifying Sewage-Water at Frankfort-on-Maine. B. Lepsius. Deutsch. Vierteljahrsschr. für öffentl. Gesundheitspf. **1891**, 230; Proc. Inst. Civil Eng. Abstracts, **105**, iii, 16—17.

The experiments here recorded have been carried out during the past three years, at the Frankfort works, under the supervision of a Commission consisting of Dr. Spiess, Mr. Lindley, Dr. Libbertz, and the author. Certain of the results obtained have been already published, and an account of the works is there given. In all eight series of experiments have been conducted, with five different systems of clarification. The various processes investigated were as follows:—

- (a.) Precipitation with sulphate of alumina and lime. Series I. to III.
- (b.) Precipitation with lime alone. Series IV.
- (c.) Simple deposition, without chemicals. Series V.
- (d.) Precipitation with sulphate of iron and lime. Series VI. and VII.
- (e.) Precipitation with phosphoric acid and lime. Series VIII.

The volume of sewage dealt with was about 30,000 cubic metres (6,600,000 gallons) per diem, and upwards of 1,000 complete and comprehensive analyses were carried out.

In its mean composition the Frankfort sewage, though considerable fluctuations were observed, does not differ materially from that of other towns, London, Paris, Dantzic, Berlin, and Breslau, with which it is contrasted in a special table. By means of a set of graphic diagrams are shown the results of the various purification processes, as evidenced by the character of the effluent as compared with the raw sewage, and the author sums up the general effect of the different modes of treatment. In all cases the suspended matters were far more efficiently dealt with than those in solution, and the appearance of the sewage water, as tested by the eye alone, was greatly improved.

In dealing with the amount of organic matter present, special consideration is given to the phosphoric-acid treatment, and a graphic diagram is appended to show the proportion of the phosphates removed at each different stage of the process, and carried off in the effluent. From this it appears that though all the added phosphoric acid is expended in enriching the sludge, the amount of phosphoric acid present in the deposit from untreated sewage is nearly twice as great as is that in the sludge from the phosphate process. The figures in milligrammes per litre are as follows:—

Phosphoric Acid Originally Present.

1. In raw sewage	67.4
2. Soluble to scenic precipitate	17.6
Total	85.0

Phosphoric Acid after Treatment.

1. In deposit in sand chamber	29.4
2. In sludge	17.4
3. In effluent	38.2
Total	85.0

Hence, instead of securing a sludge valuable for agriculture, more than twice the quantity of the phosphoric acid employed for the precipitation is carried away in the effluent, viz., 38.2 milligrammes per litre, of which about half is in suspension, and half in solution. The author points out that from this point of view it would be better not to treat the sewage with phosphate of lime at all, but to clarify it by simple deposition, and then to add the phosphate to the sludge.

In conclusion, it is stated that the experiments have demonstrated that the effect of chemical precipitation is not so greatly superior to the purification obtained by simple deposition in tanks, as to warrant the adoption of any of the above processes in preference to simple mechanical treatment. This, of course, does not hold good for sewage treatment generally, but it applies only to the conditions prevalent in the present works. It is proved, however, that in every case where tanks approaching the dimensions of those at Frankfurt are available, more especially where the length of the tanks is equally great, it is possible to obtain, by purely mechanical means, results comparing favourably with the clarification attained elsewhere in tanks of smaller size only by means of chemical treatment, and therefore at a greater cost.

The Schwartzkopff System of Sewage Treatment (Berlin).

B. Proskauer. Zeits. für Hygiene, **10**, 1891, 51; Proc. Inst. Civil Eng. Abstracts, **105**, iii. 18—19.

THE Berlin University Hygienic Institute having been requested to report on the Schwartzkopff process, to decide upon the extent to which the offensive constituents of faecal matters were eliminated by this system of treatment, the necessary bacteriological researches were entrusted to Dr. Plagge and Dr. Petri, under the superintendence of Dr. Koch; and the author was instructed to undertake the chemical investigations, and to report generally upon the experiments. The machine factory where the system is in use contained a set of water-closets, dry-closets, and urinals, resorted to daily by about 700 workpeople. The cesspit of the water-closets receives also the liquids from the urinals, which are flushed with water. The faecal matters are raised from the cesspit into a mixing tank close alongside, where they are pulped by mechanical means and mixed with chemicals which consist of: 1. Milk of lime; 2. solution of sulphate of magnesia; 3. solution of crude superphosphate; 4. solution of chloride of magnesium.

The general results of the investigation are summed up in a series of eleven conclusions, from which it follows that the process is capable of completely removing all suspended matters; but it produces but little effect upon the soluble ingredients, especially the nitrogenous substances and the ammonia. The chemical action is almost entirely due to the added lime. The treatment has a certain disinfecting action upon the sewage, and leads to a most marked reduction of the micro-organisms in the effluent; the sludge, on the contrary, remains in this respect but little affected. Other conclusions have reference to the liability of the effluent to putrefy, and to the imperfect degree of disinfection attained in the case of the poudrette. It is laid down that the effluent should not, without further treatment, be passed into the sewers, and the peat-filtration process is declared to be a disadvantage rather than otherwise.

On the Necessity for the Systematic Inspection of Wells in Cities and Towns. D. Woodman. J. Amer. Chem. Soc. 1891, **13**, 44—51.

DETERMINATIONS of the ammonia (free and albuminoid), chlorine and hardness in the water of 32 wells in the neighbourhood of Newark, New York State, U.S.A. are given. Fifteen of these well waters were found to be unfit for use, the free ammonia reaching a maximum of 0.74 parts per 100,000 in one instance, and the albuminoid ammonia 0.05 parts in 100,000, also in one case. Of these 15 samples only one contained less free ammonia than the water from a neighbouring river, opposite to a sewer outlet. A large

proportion of chlorine characterised all the waters examined. The author concludes with remarks upon the necessity for a periodical inspection of wells.—C. A. K.

On the Precipitation of Suspended Clay by Aluminic or Ferric Hydroxides or by Means of Calcium Hydrate. A. R. Leeds. J. Amer. Chem. Soc. 1891, **13**, 100—102.

IN order to hasten the deposition of the extremely finely divided clay often existing in river waters, an addition of alumina, iron salts, or lime is frequently made. The author has investigated the action more particularly of the latter substance, on impure kaolin suspended in water. As kaolin is formed by the weathering influence of water, containing dissolved carbonic acid on felspars, it seemed probable that by reversing the action, and causing lime to act on kaolin suspended in water, a portion of the basic hydrogen of the kaolin might be replaced by lime. This hypothesis was confirmed by experiment, the amount of lime absorbed varying from 20—40 per cent. of that theoretically required to replace the whole of the basic hydrogen. For this reason, lime is to be preferred for treating waters which need both softening and clarification, and which contain no appreciable amount of dissolved peaty extractive matter. In the case of waters contaminated with peaty substances, alumina is the only clarifying agent admissible; for both lime and ferric hydrate form soluble compounds with humus bodies. In fact, in some instances, when ferric hydrate is used, the yellow colour is greater after than before treatment.—H. T. P.

Disposal and Utilisation of Faecal Matters. L. Ketjen. Zeits. f. angew. Chem. 1891, 294—295.

IN parts of Amsterdam where the sewerage of 50,000 people, amounting to 54,750 cubic metres, is treated by the Liernur system, the cost has been reduced from 61 cents (Dutch) to 44 cents per head by the treatment of the liquid portions. These are mixed with lime and heated by steam in an apparatus similar to that used for working up gas liquors. By this treatment the nitrogenous matter is reduced to 0.00848 per cent., being evolved as ammonia, is collected in sulphuric acid, and the resulting ammonium sulphate sold; the water is sterilised and is separated from the calcareous solid residue by filter-pressing. In an experimental apparatus 8,750 cubic metres of sewage water required 123,000 kilos. of quicklime, 153,000 kilos. of coal, 72,000 kilos. of sulphuric acid 60° B. Labour costing 2,498 florins (Dutch).

The water had the following average composition per cent.:—

	Per Cent.
Dry matter.....	2.918
Free ammonia.....	0.193
Ammonium salts.....	0.078
Organic ammonia.....	0.055
Phosphoric acid.....	0.131
Potash.....	0.069

The filter-pressed limey cake has the composition—

	Per Cent.
Moisture.....	41.603
Calcium carbonate.....	52.270
Nitrogen.....	0.518
Potash.....	0.155
Phosphoric acid.....	1.157
Various matters.....	5.307

And is regarded by A. Mayer of manurial value for soils poor in lime, for the improvement of acid meadows, for autumn dressings of clayey soils, and especially for bean, clover, and pea crops.

The results have proved so satisfactory that a plant of a capacity of 250 cubic metres per 24 hours to deal with all the liquid of the sewage of Amsterdam is in course of construction.—D. A. L.

On the Utilisation of Chalybeate Springs for the Water Supply of Tournai. C. Pickke. J. f. Gasbel-nichtung. 34, 61-64 and 84-88.

The water on which the author's experiments were carried out was of the ordinary chalybeate kind, containing from 1 to 15 mgrms. of iron per litre in the form of ferrous carbonate, together with a large excess of free carbonic acid gas. On exposure to the air, the water became rapidly clouded owing the loss of carbonic acid and consequent precipitation of ferric hydrate, and only after standing about two days was the iron sufficiently reduced in amount to allow the water to remain clear. A small sample filtered through paper gave the following results:—

	Mgrms. per Litre.		
	(CO ₂ free and combined (as bicarbonates).)	Free CO ₂	Iron as FeO.
Fresh.....	131.5	78.5	3.24
After 6 hours.....	118.4	61.4	6.10
After 24 hours.....	106.0	48.0	9.72
After 24 hours.....	50.0	42.0	9.50
After 30 hours.....	37.0	39.0	9.45

This method for the removal of the iron becomes impracticable on the large scale as it involves the loss of two of the most valuable characteristics of spring water, viz., its uniformly low temperature, and its freedom from micro-organisms. The removal of the excess of carbonic acid, part of which is probably loosely combined with the iron in the form of a bicarbonate, by means of milk of lime is also unavailable for the same reason. If the water is broken up into the form of a spray and allowed to fall through the air from a height of about 6 ft., some carbonic acid is given off, but the loss is smaller than is generally imagined. Far better results are obtained by raising the water by means of a pump fitted with a long suction pipe; so much gas being given off in the partial vacuum, that on issuing into the air, the water becomes immediately cloudy. The ferric hydrate, however, precipitated by any of these methods is in such a fine state of division that much of it passes through the sand filters.

It is found that, on allowing the water to run over large surfaces of broken stones, the greater part of the iron crystallises out as ferrous carbonate, which is gradually converted by the air into ferric hydrate. This substance, not being crystalline, and adhering so strongly to the stones that a powerful jet of water is unable to remove it, prevents the further deposition of crystals, but at the same time apparently acts as a carrier of the oxygen of the air to the ferrous carbonate; hence, if the stream of water is continued over the stones after their having received the centing of ferric hydrate, the iron is almost instantaneously removed, and the excess of carbonic acid gas is free to escape into the air.

The apparatus for the purification of the water on this principle consists of a cylindrical vessel of 0.75 m. diameter, filled with coke to a height of 1.5 m. The water is pumped up from the wells to the top, falling on a metal plate perforated with very small holes so as to expose to the air as large a surface as possible. It then passes through the coke column, the exit pipe being made sufficiently large to prevent any portion of the coke from being covered with water, to a sand filter of the ordinary construction. The first water experimented on contained from 3 to 4 mgrms. per litre of iron (calculated as FeO), and the apparatus was found capable of dealing with from 2 to 4 cbm. per hour, the ground space occupied by the "aerator" being 1 sq. metre. The passage through the coke occupied about 30 seconds, and the ferric hydrate was found to be precipitated in particles of sufficient size to be completely retained on the sand. Other experiments were tried on a water containing 6.72 mgrms. of iron per litre, the coke column being

2 m. high and 0.99 m. in diameter, the speed of flow being 7 cbm., or 9 cbm. per 1 sq. m. of ground space per hour. In both cases the whole of the iron present in the water, except that actually dissolved, was removed, the filtrate remaining perfectly clear even on long exposure to the air.

The following table gives the results of various experiments, and shows that the removal of the iron is the more rapid the more the water originally contains, this being due to the greater rapidity with which the "aerator" becomes saturated with ferric hydrate.

Source of Sample.	Mgrms. per Litre.		Litres per 1 Sq. M. per Hour.	Speed of Flow through Aerator in Seconds.
	FeO.	CO ₂ Free.		
Well.....	2.17	23.0	2,300	30
Exit of aerator..	0.26	17.0		
Exit of filter....	0.10	11.0		
Well.....	1.82	25.0	2,300	30
Exit of aerator..	0.30	13.0		
Exit of filter....	0.15	8.0		
Well.....	2.88	42.0	7,000	13
Exit of aerator..	0.60	18.0		
Exit of filter....	0.20	12.0		
Well.....	2.94	49.0	6,000	15
Exit of aerator..	0.50	30.0		
Exit of filter....	0.15	12.5		

—F. H. L.

PATENTS.

An Improved Sewage Filter. J. Lowe, Manchester. Eng. Pat. 16,836, October 22, 1890. 6d.

This filter is intended for town sewage. It consists of a large, cylindrical, wrought-iron vessel, capable of sustaining a steam-pressure of 200 lb per sq. in., and fitted up with valves, pipes, and a filter-bed impervious to all solid matter. The crude sewage is driven through the filter by means of the steam-pressure.—P. J. H.

Improvements in Apparatus for Automatically Regulating the Supply of Precipitating Materials to Sewage, and for other Analogous Purposes. J. E. Keirby, Swinton. Eng. Pat. 2729, February 14, 1891. 8d.

The supply of precipitant is regulated by the raising or lowering of a cone in the mouth of the supply-hopper; this is worked by means of a wheel and chain connected with a float placed in the sewage chamber, or in the main outfall drain. The flow of sewage may be registered by connecting the float-chain with a dial or other indicator.—P. J. H.

(C)—DISINFECTANTS.

PATENTS.

Improvements in the Manufacture of Disinfectants or Antiseptics. J. V. Johnson, London. From F. von Heyden, Radebeul, Germany. Eng. Pat. 9103, June 12, 1890. 6d.

The invention consists in obtaining aqueous solutions of the cresols, xylenols, and higher-boiling phenols, which can be diluted to any desired extent without separation of the phenols, these higher-boiling phenols being superior to other phenols as disinfectants. The solutions can be made by dissolving the phenols in aqueous solutions of the sodium salts or other alkaline or alkaline-earth salts of various organic acids, among which are mentioned the *o*-hydroxy-

benzene carboxylic acids, the *o*-hydroxybenzene sulphonic acids, benzoic acid, benzene, carboxylic acids, and benzene sulphonic acids, and their homologues. The salts of the corresponding acids of the naphthalene series may also be used. As an example the following is given: "When to 12 parts by weight of sodium salicylate, 10 parts by weight of water are added, no solution takes place at low temperatures, but when 5 parts by weight of cresol are added and mixed with these ingredients a clear solution is obtained which can be diluted as required without separation of the cresol." These solutions are suitable as surgical antiseptics. A table of the various organic salts and the proportions in which they should be mixed with water and the phenols is given.

A valuable disinfecting fluid can also be made by mixing cresol with caustic soda or caustic lime, and water.

—H. S. P.

A Method of rendering Antiseptic and Preparing Gauze, Lint, Ligatures, and other Fabrics for Use in Surgery. C. R. C. Tielborne and F. T. Henston, Dublin. Eng. Pat. 11,985, July 31, 1890. 4d.

THE gauze, &c. is rendered antiseptic by depositing zinc sulphite in the fibre. The fabric is boiled in water for some time; to this zinc sulphate in the proportion of 12 oz. to 2 galls. is then added, and after boiling again, an equivalent amount of sodium sulphite (in concentrated boiling solution) and also a small amount of some antiseptic non-poisonous dye are further added. The whole is allowed to stand till quite cool, say 8—12 hours. To free the fabric from soluble by-products it is then run twice, by means of rollers, through running water, to which an antiseptic has been added.

The zinc sulphite may also be deposited in the fibre, by using other salts, such as zinc chloride and calcium sulphite; or (2) by means of a solution of zinc sulphite in sulphurous acid, the sulphurous acid being afterwards driven off by heat or neutralised.—P. J. H.

XIX.—PAPER, PASTEBOARD, Etc.

PATENTS

A New or Improved Metallic Foil-Coated Air-tight and Grease-proof Paper. F. W. Crowther, London. Eng. Pat. 7971, May 22, 1890. 4d.

THE inventor coats a grease-proof paper such as that known as vegetable parchment paper, with tin or other metal.

—E. J. B.

Process of Impregnating Fibrous, Porous and Cellular Bodies, Working the Impregnating Material or Compound, and the New Article resulting therefrom. B. J. B. Mills, London. From E. T. Greenfield and J. Nagel, New York, U.S.A. Eng. Pat. 10,807, July 11, 1890. 6d.

THE inventors impregnate such articles as paper tubes with melted pitch by a series of short immersions alternated with rests. In this way the impregnation is effected without the charring which would ensue if the article were allowed to remain in the melted pitch.—E. J. B.

Improved Apparatus for Recovering Sulphurous Acid used in the Manufacture of Paper Pulp from Wood. C. Kellner, Vienna. Eng. Pat. 7362, April 29, 1891. 6d.

THE inventor describes and gives drawings of an arrangement for condensing the steam and sulphurous acid gas given off during the operation of boiling wood in a solution of an acid sulphite.—E. J. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Action of Sunlight on Organic Compounds. H. Klinger and O. Staudke. Ber. 24, 1340—1346.

See under IV., page 690.

The Simultaneous Action of Air and Light on a number of Organic Compounds. A. Bidet. Bull. Soc. Chim., 1891, 5, 13—20.

See under IV., page 693.

Aspergillin; a Pigment Analogous to Blood-Hæmatin. G. Linossier. Compt. Rend. 112, 489—492.

THE spores of *Aspergillus niger* contain a black pigment which may be extracted with dilute aqueous ammonia and precipitated from this solution by hydrochloric acid. A voluminous, floccy precipitate is thus obtained which dries up to a black mass. This pigment in its physical, and certain of its chemical, properties closely resembles blood-hæmatin: both substances, for example, contain a little iron; both are reducible by sodium hyposulphite, and their reduction products re-oxidisable to the original substances by exposure to air. The author is further investigating the chemical and physiological properties of this pigment.—E. B.

Pyrogenic Transformation of Camphophenolsulphonic Acids into Homologues of Phenol. P. Cazeneuve. Compt. Rend. 112, 730—732.

WHEN a mixture of the barium salts of the five camphophenolsulphonic acids previously described (compare this Journal, 1890, 647) is submitted to dry distillation, hydrogen sulphide, sulphurous anhydride, carbonic anhydride, methane, and probably propane, or propylene, are evolved, and a liquid distils over. This liquid contains very small quantities of hydrocarbons and considerable quantities of phenols; ortho- and meta-cresol were isolated from the mixture; analyses of the higher boiling fractions gave results agreeing with those required by mixtures of cresols, propylphenols, and cymophenols.—F. S. K.

Terebenthene. R. Varet. Compt. Rend. 112, 732—734.

GESTAVSON has shown that, when cymene is treated with bromine in presence of aluminium bromide it is decomposed quantitatively into pentabromotoluene and isopropyl bromide; the author has made some analogous experiments with terebenthene, which is considered by some to be a hydrocymene, and finds that it behaves quite differently.

When essence of terebenthene is warmed gently with anhydrous aluminium chloride a violent reaction takes place and a tarry product, from which cymene and toluene can be isolated, is obtained. On gradually adding aluminium chloride to a well-cooled carbon bisulphide solution of terebenthene an energetic reaction occurs and the terebenthene is converted into meta- and tetra-terebenthene, small quantities of cymene and other hydrocarbons being also produced. When terebenthene is gradually added to a well-cooled solution of bromine, containing aluminium chloride in suspension, hydrogen bromide is evolved, and various bromo-derivatives of polymerides of terebenthene are formed, together with small quantities of isopropyl bromide.—F. S. K.

The Conversion of Cupreine into Quinine. E. Grimaux and A. Arnaud. Compt. Rend. 112, 774—775.

CUPREINE, which has been prepared from the *Quina cuprea* and *Remijia pedunculata* by Paul and Cowley, is a base soluble in alkalis, and is apparently phenolic in character. The relationship of cupreine, $C_{19}H_{22}N_2O_2$, to quinine,

$C_{10}H_{12}N_2O_2$ is the same as that of phenol to its methyl ether. The transformation of euprepine into quinine is effected by treating a solution of euprepine in methyl alcohol with sodium and then with methyl iodide, the temperature, starting from zero, being gradually raised during several hours. Under these conditions quinine itself is not formed, but quinine mono- and dimethyl iodides. When operating in a closed vessel with an excess of methyl iodide only the latter body is produced. Methyl-euprepine dimethyl iodide agrees in all its properties with quinine-dimethyl iodide, as is shown by the following figures:—

	Quinine dimethyl iodide.	
	Synthetic.	Natural.
Melting point (with partial decomposition).	167–168 C.	167–168 C.
Rotatory power α_D^{20}	+150°8	+151°6
Percentage of iodine	41·34	41·77

If the methyl iodide be replaced by methyl chloride, free quinine is formed. A mixture of one molecule of euprepine, one atom of sodium, and one molecule of methyl chloride, dissolved in methyl alcohol, is heated to 100 C. in a closed tube. The product of the reaction is evaporated to dryness, washed with a dilute soda solution in order to remove any unaltered euprepine, and finally extracted with ether, which dissolves the quinine. After conversion into sulphate of quinine the product resembles the natural article in all respects. It is an interesting fact that ethyl derivatives do not occur in vegetable products. Thus, the alkaloid of the hemlock consists of a mixture of cicutine and methyl-cicutine; morphine is accompanied in opium by methyl-morphine, or codeine; quinine is shown to be methyl-euprepine; and eugenol, and the essences of gaultheria and anise-seed, &c., are the methyl ethers of phenolic bodies. The cause of this phenomenon must be sought for in the mode of nutrition of plants, which absorb carbonic acid from the air and transform it by reduction into methyl aldehyde and then into methyl alcohol.—H. T. P.

A Vegetable Hematin, Aspergillin. G. Linossier. *Compt. Rend.* **112**, 807–808.

In this paper the author shows that *aspergillin*, which he has recently prepared from *Aspergillus niger*, (*Compt. Rend.* **112**, 189, see preceding page), is in no way identical with *pauillon* obtained from *Palmella cruenta*, and described by Philipson in 1879. H. T. P.

Isocinchonine. E. Jungfleisch and E. Léger. *Compt. Rend.* **112**, 942–944.

Hesse has recently expressed an opinion that his isocinchonine (this Journal, 1888, 350) is identical with the *cinchonine* obtained by the authors. The latter have repeated Hesse's experiments, dissolving in the cold, 60 grms. of cinchonine sulphate in 360 grms. of pure concentrated sulphuric acid, pouring into cold water after 24 hours at 17°, then supersaturating with soda, cooling and extracting with ether. The ethereal extract left on evaporation, Hesse's isocinchonine, was dissolved with the aid of heat in dilute hydrochloric acid, and when neutralised and cooled the solution yielded *cinchonine hydrochloride*; the mother-liquor after concentration was treated with soda; the alkaloïds thus liberated, extracted with ether and treated with colourless hydriodic acid in slight excess, yielded crystals of cinchonine hydroiodide, after removal of all the cinchonine and cinchonidine, 11·8 grms. of the former and 12·7 of the latter were obtained, a non-crystallisable base remained. These results indicate that Hesse's isocinchonine is really a mixture. The authors deny the imputation as to the questionable purity of their materials.—D. A. L.

Condition of Tartaric Acid in Aqueous Solutions. Aignan. *Compt. Rend.* **112**, 951–953.

In order to decide whether tartaric acid in solution existed as a polymer or hydrate in state of dissociation, the author has made comparative osmometric observations with solutions of tartaric acid and solutions of sugar, and his results support the view that tartaric acid in aqueous solution exists in the state of a polymer $(C_4H_6O_6)_2$ partially dissociated and conforms with a law based on the results of Biot's experiments to the effect that:—the proportion of the compound $(C_4H_6O_6)_2$ dissociated by solution is equal to the proportion of solvent in the liquid examined.—D. A. L.

Compounds of Mercuric Chloride. G. André. *Compt. Rend.* **112**, 995–998.

Crystals of the composition $4 ZnCl_2 \cdot 12 HgCl_2 \cdot 10 NH_3 + 2 H_2O$ are obtained when boiling mercuric chloride is gradually added to saturation to a hot solution of zinc oxide dissolved in concentrated ammonium chloride. The crystals are readily soluble in hydrochloric acid, insoluble in, but decomposed by, hot water, yielding an anhydrous mixture of zinc oxychloride and oxydimereurammonium chloride. A crystalline double chloride of analogous character and composition, $2 ZnCl_2 \cdot 12 HgCl_2 \cdot 6 NH_3 + \frac{1}{2} H_2O$, is obtained by dissolving simultaneously 20 grms. zinc oxide and 20 grms. yellow mercuric oxide in a boiling solution containing 100 grms. of ammonium chloride. By agitating 1 mol. of mercuric chloride in aqueous solution with 2 mols. of aniline a white precipitate of the composition $NH_2C_6H_5 \cdot HgCl_2$ is formed, but by mixing aqueous or alcoholic solutions of mercuric chloride and aniline with excess of aniline, compounds are obtained containing excess of mercury in relation to the chlorine, probably as oxide. When, however, mercuric chloride in the proportion of 1 mol. is added gradually to a proportion of 8 mols. of aniline in boiling solution, a yellow substitution product of the composition $5 NH_2C_6H_5 \cdot HgCl_2 + 2 HgCl_2$ is precipitated, which is very stable; heating with water or alcohol, even for hours, simply converts it into $3 NH_2C_6H_5 \cdot HgCl_2 + 2 HgCl_2$. Of the corresponding benzylamine compounds, $C_6H_5 \cdot CH_2 \cdot NH_2 \cdot HgCl_2$ is obtained as a white precipitate by adding one molecular equivalent of benzylamine in solution to 4 molecular equivalents of boiling mercuric chloride, or by boiling 1 mol. of mercuric chloride with 2 mols. of benzylamine, both dissolved in alcohol, whereas the compound $NHCH_2C_6H_5 \cdot HgCl_2$ is obtained as a white precipitate by pouring 1 molecular equivalent of mercuric chloride into 4 mols. of benzylamine in boiling aqueous solution. This compound is insoluble, whilst the additive compound just mentioned is soluble in boiling water.—D. A. L.

Antiseptic Properties of Amethylcamphophenolsulphone. P. Cazeneuve and Rodet. *Bull. Soc. Chim.* 1891, **5**, 649–650.

AMETHYLCAMPHOPHENOLSULPHONE is only a feeble antiseptic agent compared with the true aromatic phenols, and it has no poisonous effects on animals. Its antiseptic action on *Bacillus anthracis* begins to be manifest in solutions containing 1 part in 100, on *Bacillus fluorescens liquefaciens* in solutions containing 1 part in 70, and on *Micrococcus pyrogaenus aureus* in solutions containing 1 part in 50.—F. S. K.

Methyl Iodide. L. H. Friedburg. *Jour. Amer. Chem. Soc.* 1891, **13**, 144.

INSTEAD of the usual method of preparation, the following were tried:—

(a.) Iodine was dissolved in methyl alcohol, and sulphuretted hydrogen was then passed to decolourisation of the solution. In addition to methyl iodide, sulphur compounds were obtained.

(b.) Instead of sulphuretted hydrogen in the preceding, sulphur dioxide was used. Methyl iodide was formed in small quantity, but the main product consisted of various ethers.—T. L. B.

Note on Acid Calcium Tartrate. L. H. Friedburg. Jour. Amer. Chem. Soc. 1891, **13**, 111.

THE method of purifying the mother-liquors from the tartaric acid manufacture being to form acid calcium tartrate, the author proposes the use of the solution of tartrate so obtained for the manufacture of the salt contained in it. The salt could then be used advantageously either alone or mixed with cream of tartar for baking powders.

T. L. B.

PATENTS.

An Improvement in Ozone Water and in the Method of Making same. J. C. Dittich, New York, U.S.A. Eng. Pat. 3118, February 20, 1891. 4d.

THE invention has for its object the making of ozonised water which will keep for an indefinite length of time even when exposed to light or to a high temperature. This is accomplished by adding a phosphite or hypophosphite to the water, to the amount of about 1 part of the phosphite or hypophosphite in 1,000 parts of water, either before or after charging the water with ozone.—H. S. P.

Ozonizing Apparatus. J. Guenet, Paris, France. Eng. Pat. 6374, April 14, 1891. 6d.

THIS is an apparatus for making ozone, and a drawing of the apparatus accompanies the specification. It consists of an "ozonising tube," an induction coil, and bellows with compressed air reservoir, the whole enclosed in a case. The ozonising tube is of glass, and within it are placed three or more smaller glass tubes. The large outer tube is connected by two terminal screws with the induction current from the induction coil. Around the inner smaller tubes platinum wires are coiled which are twisted together at one extremity of the tubes and connected with one of the terminals on the larger outer tube. Rods made of any good metal conductor are placed inside the smaller tubes and the ends of these rods are connected to each other by a platinum wire and this is connected to the other terminal on the outer tube. Compressed air is forced through the large outer tube, and when an electric current is passed through the apparatus by attaching the coil to a battery, the air becomes ozonised and is drawn off at an exit tube attached to the large outer tube.—H. S. P.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

Note on the Calibration of Burettes. D. Carnegie. Chem. News, **64**, 42—43.

THE method of calibrating burettes given in the text-books is roughly as follows:—

The burette is filled with water, and successive portions—corresponding to 5 cc. or so—are run out into dry beakers. From the weights of these successive portions a table of corrections can easily be deduced. This method, in the case of an ordinary 50 cc. burette and with 5 cc. tests, involves at least 11 weighings and 10 level-readings.

The method of calibration the author would suggest is, he believes, more accurate than the above, and involves no weighing whatever; for it is quite a matter of indifference to the chemist, whose measurements are all relative, whether he adopts as his unit the true cubic centimetre or an arbitrary one.

The principle of the method consists in causing a constant volume of liquid to slide in the burette (so that it may be made to assume any desired position therein), and then reading off its length in terms of the burette divisions.

In the Fig. the burette B is attached by means of caoutchouc tubing C to a reservoir R, which is filled with water, and which can easily be raised or lowered by sliding the clamp K along S. On the surface of the water in the burette there is a small column of carbon bisulphide W, which obviously can be made to assume any desired position in the burette by either raising or lowering R, and then turning the stopcock *n* very gently.

In the first experiments mercury was used in place of water in R, and water instead of carbon bisulphide as a movable index. But this combination was unsatisfactory; it was found to be exceedingly difficult to read the level *l*, both on account of the convexity of the mercury surface and also on account of the peculiarly disturbing light reflection from the bounding water-mercury surface.

The combination, water and carbon bisulphide, works admirably if the following precautions be taken:—

The burette must be thoroughly cleaned from grease and dust before calibration. The reservoir R is then filled with freshly-distilled water, and matters are so arranged that the level of the water stands at *g*, the lowest graduation of the burette. A long thistle funnel is then inserted into the burette, and a small quantity (say 5 cc.) of recently distilled carbon bisulphide is poured gently on the surface of the water. Under these circumstances the carbon bisulphide, in spite of its higher specific gravity, floats on the water, and exhibits two easily localised concave menisci. It is well to shake the carbon bisulphide up with distilled water so as to thoroughly saturate it, and to tint it slightly with iodine before pouring it into the burette.

The method of procedure is obvious. In altering the position of the carbon bisulphide index, it is well to let it rise a little higher in the burette than the required graduation, and then lower it by careful manipulation of the stopcock *n*. The burette should of course be kept stoppered as much as possible during the calibration.

The method works satisfactorily only when the calibration is effected as described—from below upwards.

The readings obtained can be used for calibration as described in detail in Bunsen's "Gasometry."

In order to avoid errors of parallax in reading off the levels of the carbon bisulphide column, the author has a silver strip on the back of the burette. This mirror strip, which does away with all floats and similar devices for avoiding errors of parallax in the subsequent use of the burette, is easily made as follows:—The burette, having

been thoroughly cleaned externally, is corked air-tight, and then inverted in a tall cylinder containing an alkaline silvering fluid.* After some time it is withdrawn, and allowed to become thoroughly air-dried. The silver can then be easily removed from the front and sides by scraping, followed by a final rubbing with a rag moistened with dilute nitric acid. The strip of silver backing the burette is then fixed by one or two coats of varnish.

In reading such a burette it will be found advantageous to look at the meniscus through a slit cut in a sheet of white glazed paper, held at an angle to the vertical. The burette graduations are also rendered very much more distinct by rubbing the front of the burette first with a piece of flannel on which a paste of turpentine and mercuric iodide has been placed, and then with a dry cloth.

Employment of the Calorimetric Bomb for Determining the Heat of Combustion of Coal. Scheurer-Kestner. Bull. Soc. Chim. 1891, 5, 941-945.

Also abstracted from Compt. Rend. 112, 233-234; this Journal, 1891, 659.

INORGANIC CHEMISTRY.— QUALITATIVE.

The Influence exerted by Various Neutral Potassium Salts on the Solubility of Potassium Bitartrate. C. Blauz. Compt. Rend. 112, 808-811.

See under XVII., page 717.

Detection of the Sulphur not Combined with Hydrogen in Illuminating Gas. "L. Hosvay de N. Hosva." Bull. Soc. Chim. 1890, 4, 714-715.

Paper soaked in thallic hydrate is readily blackened when held over a Bunsen burner that has struck back. This blackening is not due either to hydrocarbons or to sulphuretted hydrogen contained in the gas, but, according to the authors, to the sulphuretted hydrogen formed as a product of the incomplete combustion of the bodies containing carbon combined with sulphur which are in the gas. The hydrogen with which the liberated carbon enters into reaction may be either free or combined. The decomposition takes place at a temperature between 355 and 360 C. To test for the presence of such sulphur compounds in coal-gas, it suffices to hold a piece of lead acetate paper over a Bunsen flame, burning at the bottom, for one minute. The sulphuretted hydrogen contained as such in the gas will take considerably longer to blacken the paper.

A New Method for the Separation of Iron from Cobalt and Nickel. G. A. Le Roy. Compt. Rend. 112, 722-723.

In estimating nickel and cobalt by the electrolytic method usually employed, the presence of manganese is without influence on the result, but iron, if present, must be previously removed; the author describes a process by which the tedious separation of the iron before electrolysis is obviated.

The metals, in the highest state of oxidation, are dissolved in sulphuric acid, a very small quantity of a non-volatile organic acid, such as citric acid, is added, and then a concentrated ammoniacal solution of ammonium sulphate; the solution is then electrolysed with a current from two Bunsen cells (=300 cc. of explosive gas per hour), wherein the manganese is deposited at the positive pole and the nickel and cobalt, together with the iron, at the negative pole. When deposition is complete, the negative

electrode is washed with distilled water, and then immersed in a fresh concentrated ammoniacal solution of ammonium sulphate, where it serves as the positive electrode, a clean piece of platinum, previously weighed, serving as the negative electrode. A current (= 100 cc. of explosive gas per hour) is then passed through the solution; under these conditions the metals on the positive electrode are oxidised and the nickel and cobalt pass into solution, being finally deposited in the metallic state on the negative electrode; the iron, on the other hand, is transformed into insoluble ferric hydrate, and remains attached to the positive electrode or suspended in the solution.—F. S. K.

New Process for Estimating the Oxygen dissolved in Water. G. Linossier. Bull. Soc. Chim. 1891, 5, 63-66.

The principle of the method is as follows:—The oxygen is absorbed by an alkaline solution of ferrous tartrate, added drop by drop to the water, phenosafranine being used as indicator. So soon as the free oxygen has disappeared the first drop of ferrous salt added in excess decolorises the liquid. The estimation is carried out in a half-litre flask, furnished in its lower portion with a stop-cock. Into this flask are introduced 400 cc. of mercury, then 20 cc. of soda (36° B.), 20 cc. of a 20 per cent. solution of Rochelle salt, a drop or two of an alcoholic solution of phenosafranine, and lastly water. A two-holed rubber stopper is then placed in the neck of the flask, care being taken that no air remains in the flask; through one hole of the stopper is introduced the socket of a Mohr's burette previously filled with a standard solution of ferrous sulphate; the other communicates with a tap funnel for the introduction of the water to be examined. When all is ready the lower cock is opened, and if the apparatus proves to be tight, ferrous sulphate solution is very carefully run in until the rose colour of the solution in the flask first disappears; 50 cc. of the water to be examined are now introduced by the aid of the tap funnel, mercury escaping from the lower cock as the water flows in from the funnel. The rose colour reappears, and the solution is then directly titrated with the ferrous sulphate until the colour once more disappears. Agitation is easy and complete by aid of the mercury in the flask.

A second determination may be carried on directly the first is ended, by simply introducing another 50 cc. of water and again titrating; and the number of successive determinations is limited only by the capacity of the flask. The first two determinations are generally slightly low.

With regard to the calculation of results it is stated that the quantity of dissolved oxygen as calculated directly from the amount of iron solution is lower than the quantity obtained by extraction with the pump. Keeping the same proportion of soda and Rochelle salt, however, the relation of iron solution used to oxygen dissolved in the water is a constant one, and therefore all that is necessary is to ascertain once for all the factor for the iron solution by aid of a known oxygen solution. There is no necessity to continuously standardise the ferrous sulphate solution, as this may be kept for a very considerable time if strongly acidified with sulphuric acid and it kept under oil. The presence of nitrates and nitrites is stated not to impair the accuracy of the results; among organic substances only such as exercise an energetic reducing action, for instance glucose, form an obstacle to the use of the process.—T. L. B.

Estimation by Titration of Dissolved Carbon Dioxide in Water. A. R. Leeds. J. Amer. Chem. Soc. 1891, 13, 98-99.

The amount of lime required to precipitate the dissolved calcium and magnesium carbonates in natural waters is generally under estimated, because any excess of carbon dioxide above that necessary to form calcium and magnesium bicarbonates is in most cases neglected. The free carbon dioxide may be readily estimated in waters by adding a few drops of a solution of phenol-phthalein and titrating with decinormal sodium carbonate until a pink tinge is obtained.

* Suitable fluids are described in Roscoe and Schorlemmer's "Practical Chemistry," vol. II, Part I, p. 461.

This occurs when all the carbon dioxide is combined as sodium bicarbonate. In the case of soft waters 500 cc. of the sample may be taken for titration, whilst of hard waters 100 cc. are sufficient. Too small an amount of the indicator should not be employed; about 10 drops of a strong solution added to 100 cc. of water will suffice.

—H. T. P.

Are Chemists generally prepared to Abandon Clark's Method for Estimation of Hardness in Waters? A. R. Leeds. J. Amer. Chem. Soc. 1891, 13, 114—119.

THE objects in view when hardness is determined are as follows:—

1. *Simply to place the water in the category of hard or soft waters.*

2. *Soap-destroying power.* For factory use the soap-destroying power is best found by actual trial with the water and soap to be employed. The results obtained by Clark's method unless special care be taken and time be of little moment, often vary widely from the true calcium carbonate equivalent, and do not necessarily indicate the real soap-destroying power.

3. *Boiler-incrusting solids.* Any deductions made from the results of the soap test, as regards scale-forming properties of a water, are little better than guess-work.

4. *Character and amount of chemicals required to precipitate the scale-forming substances.* Here again the process is faulty. In practice, a trial should always be made by adding the calculated amounts of reagents (generally lime or soda, or both) to the water, for the actual and theoretical results after treatment frequently differ.

For these reasons the author has abandoned Clark's process. A number of experiments, however, were made to test the capabilities of the method.—H. T. P.

Electrolytic Quantitative Separation of Metals. T. O'Connor Sloane. J. Amer. Chem. Soc. 1891, 13, 140—142.

THE author considers that greater recognition of the influence of difference of potential is required. For the decomposition of every solution a definite and absolutely fixed voltage is required; the strength of current affects only the condition of the deposit. The amperage of the current should not be broadly stated without reference to absolutely fixed conditions of electrodes. It would seem obvious, he continues, that a definite and absolutely fixed difference of potential being required for the decomposition of each compound, the voltage could be made the basis for analytical work; it would be possible to effect successive separation of metals from the same solution by modifying the voltage. It is suggested that work be done on these lines, two factors always being stated—difference of potential, and amperage per unit area of cathode.—T. L. B.

A Rapid Method of Estimating Nitrates in Potable Waters. G. Harrow. J. Chem. Soc. (Trans.), 1891, 320—323.

THIS method depends upon Griess's nitrite test with α -naphthylamine and sulphamic acid, the nitrates present being reduced to nitrites by the addition of a small quantity of zinc-dust. The test solution used consists of 1 gm. α -naphthylamine, 1 gm. of sulphamic acid, 25 cc. of concentrated hydrochloric acid dissolved in water boiled with animal charcoal and diluted to 500 cc. Standard solutions of potassium nitrate are also prepared containing respectively 1.0, 0.1 and 0.01 part of nitrogen per 100,000. 50 cc. of the water to be tested and of each of the standard nitrate solutions are placed in separate beakers standing on a sheet of white paper; 10 cc. of the test solution are added to each and then a small quantity (7—8 mgrms.) of zinc-dust. After 15 minutes a comparison of the colours will indicate approximately the amount of nitrates present in the water under examination, and an accurate determination may be obtained by using Nessler glasses and determining the degree of dilution required to bring the colour obtained from the water under examination equal to that of the

weakest standard. The advantages claimed for this process are its rapidity and simplicity and the small quantity of water required.—A. K. M.

ORGANIC CHEMISTRY.—QUALITATIVE.

The Use of Phenylhydrazine for the Detection of Sugars. Maquenne. Compt. Rend. 112, 799—802.

PHENYLHYDRAZINE is a very useful reagent for precipitating and distinguishing certain sugars when in admixture with other bodies; but it fails when only small quantities of the sugar under examination are available, and when other reducing bodies are present. For instance, it is impossible by the use of phenylhydrazine alone to distinguish dextrose and mannose from levulose. The author finds, however, that the weight of osazone precipitated in a certain time under standard conditions varies widely for the different sugars, but is a constant quantity for each particular species. The numbers given in the following table were obtained by heating to 100° C. for 1 hour a mixture of 1 gm. of sugar, 100 cc. of water, and 5 cc. of a solution containing per 100 cc. 40 grms. of phenylhydrazine and 40 grms. of glacial acetic acid. After cooling, the precipitate was collected on a tared filter-paper, washed with 100 cc. of water, dried at 110° C., and weighed.

Sugar employed.	Weight of Osazone.	Remarks.
Serbian, crystallised ...	Grms. 0.82	Turbidity in 12 minutes.
Levulose, crystallised .	0.70	Precipitate after 5 minutes.
Xylose, crystallised ...	0.49	Precipitate after 13 minutes.
Glucose, anhydrous ...	0.32	Precipitate after 8 minutes.
Arabinose, crystallised	0.27	Turbidity in 30 minutes.
Galactose, crystallised	0.23	Precipitate after 30 minutes.
Rhamnose, crystallised	0.15	Precipitate after 25 minutes.
Lactose, crystallised ..	0.11	Precipitate only after cooling.
Maltose, crystallised ..	0.11	Precipitate only after cooling.

Using solutions of only half the above strength, the sugars come practically in the same order, excepting that levulose takes the lead. It is easy by this method to distinguish between glucose and galactose, for instance, but it is most useful in the study of the polyglucosides. It is only necessary to compare the weight of osazone yielded by the inversion products of the sugar being examined, with the amount of osazone obtained from a mixture of glucoses most likely to be similar in composition to the said inversion products. Various polyglucosides were treated in this manner, sulphuric acid being used to effect the inversion. Below are the results obtained:—

Nature of the Sugar.		Weight of Osazone.
		Grms.
1.	{ Cane sugar	0.71
	{ Dextrose and levulose (of each 0.526 gm.) ...	0.73
2.	{ Maltose	0.55
	{ Dextrose (1.052 gm.)	0.58
3.	{ Rutinose, crystallised	0.48
	{ Levulose, dextrose, and galactose (of each 0.303 gm.)	0.53
4.	{ Lactose, crystallised	0.58
	{ Dextrose and galactose (of each 0.500 gm.) ...	0.70

Operating in this manner the author confirms the observation of Alekhine that melezitose yields only dextrose on complete inversion.—H. T. P.

The Detection of Margarin in Butter. R. Lédé. *Compt. Rend.* 112, 813—815.

1.5 cc. of a strong solution of cane sugar are placed in a test-tube marked at 10 cc. The tube is placed in warm water, and the butter to be tested is added in small quantities until the 10 cc. mark is reached. A cork is then inserted, the butter and syrup are rapidly mixed by shaking, and the tube is fastened to one end of a length of cord and whirled round quickly for a short time. Under these conditions pure butter yields a clean transparent layer of butter-fat and a voluminous layer of a whitish emulsion. In the case of margarin, or butter containing margarin, the separated fat is milky and turbid, owing to the presence of emulsified air, which margarin always contains. By means of this test it is possible to detect an adulteration of butter with 20 per cent. or even 15 per cent. of margarin. Another distinction between the two fats is that melted margarin or butter containing margarin remains fluid much longer than melted pure butter. Pure butter becomes solid and opaque when the margarin is still fluid and semi-transparent. Of course, in making comparisons of this kind, it is necessary to work under strictly identical conditions throughout.—H. T. P.

Reaction for Tartaric Acid. E. Mohler. *Bull. Soc. Chim.* 1890, 4, 728—729.

A one per cent. solution of resorcinol in strong sulphuric acid gives a reddish-violet colouration with tartaric acid when the mixture is heated gently to about 125° C.; the colour darkens on further warming; at 190° C. carbonisation ensues. The reaction serves as a delicate test for tartaric acid, a few drops of the reagent being added to the residue left after evaporating the suspected solution to dryness. $\frac{1}{1000}$ mgrm. of the acid can be detected in this way. Neither succinic, malic, citric nor benzoic acid react in this way. Salts of the acid can be similarly tested; in presence of organic matter the tartaric acid must first be isolated. Nitrous and nitric acid must also be absent, since they both give a blue colouration with resorcinol which masks the other reaction. Attempts to isolate the colouring matter were unsuccessful; it is destroyed on the addition of water.

Pyrogallol and phloroglucinol give analogous reactions, the former producing a violet, the latter a red colouration.—C. A. K.

Notes on Certain Reactions for Tyrotoxinon. H. A. Weber. *J. Amer. Chem. Soc.* 1890, 12, 485—487.

The author has examined numerous examples of poisonous cheese for the presence of tyrotoxinon, by Vaughan's test. The test consists in digesting the sample with water at the ordinary temperature, and extracting the aqueous solution with ether after making it alkaline with sodium carbonate. After distilling off the ether, the residue is tested by means of ferrie chloride and potassium ferricyanide when Prussian blue is precipitated and by the addition of a few drops of a mixture of phenol and strong sulphuric acid, when a reddish yellow colouration ensues which turns permanently violet after standing for some hours. All the samples examined gave these two reactions, but when tested physiologically they failed to show the presence of tyrotoxinon, which is an active poison. The above reactions are therefore not due to tyrotoxinon at all, but according to the author's results to the presence of an organic base, probably an amine on the one hand, which gives the Prussian blue reaction, and to butyric acid on the other hand, which gives the colouration with phenol. Both these substances are liable to occur in any old sample of cheese, milk, or cream,

and would be extracted together, probably in the form of a salt, on treatment with ether. It is these bodies also which cause the orange-red colouration that diazobenzene gives with phenol, when the former is extracted from whey by means of ether, a reaction the diazobenzene does not give alone.—C. A. K.

The Detection of Rosin Oil in Fatty and Mineral Oils, especially Train Oil. A. Grittner. *Zeits. f. angew. Chem.* 1891, 265—266.

THE rosin oils examined by the author gave the characteristic colour when treated either by Morawsky's process (this Journal, 1889, 572) or by Holde's (this Journal, 1888, 526; and 1890, 419). Dark coloured rosin oils are best examined by the latter method owing to the deep colour of their solution in acetic anhydride. Mixed with rape oil, rosin oil may be detected by Holde's test when only 1 per cent. is present, the limit in the former case being 0.5 per cent. The use of the weaker sulphuric acid (sp. gr. 1.53) is advisable when only small amounts of rosin oil are expected, as it remains almost colourless when shaken with pure rape oil, while acid of the sp. gr. 1.624 becomes dark yellow.

Train oil must be extracted with 90 per cent. alcohol, and the clear alcoholic solution examined; the acid being best added down the side of the tube so as not to mix with the solution. Morawsky's reaction is also here more delicate, but if the train oil is dark in colour Holde's must be employed. When rosin, shellac, or other resins are present the oil must be saponified and the rosin oil looked for in the unsaponifiable portion, as these substances also give the red colour. Mineral oils when dark in colour should be treated with the weaker acid, especially as the rosin oil reaction is given just as sharply as with the stronger.

Schadler's process of mixing five parts of train oil with one of syrupy phosphoric acid to obtain a red colour when rosin oil is present, is not reliable, the colour being at best only faint, and very different in appearance with different samples of rosin oil.—F. H. L.

Analysis of a Mixture of Bees'-wax, Paraffin, Stearin, and Stearic Acid. E. Jean. *Bull. Soc. Chim.* 1891, 5, 3—5.

THREE to four grms. of the mixture are heated to boiling in a flask with 60 cc. of 96 per cent. alcohol, the solution allowed to cool, and titrated with semi-normal alkali, employing phenolphthalein as the indicator. As the bees'-wax is only very slightly soluble in cold alcohol, the total acidity may be taken as due to the stearic acid. To determine the paraffin and the methyl alcohol (of the bees'-wax), 3—4 cc. of 50 per cent. caustic soda solution are added to the contents of the flask, neutralised as above, and the whole saponified by heating to boiling for one hour, the flask being connected with an upright condenser. After the saponification is completed, the excess of alcohol is distilled off, the residue transferred to a crucible, mixed with dry silica and asbestos, and then dried at 100° C. This dried residue is next powdered and extracted with either chloroform or with petroleum ether, which dissolves the paraffin and the

melissyl alcohol. To separate the two constituents taken up by the solvent, the latter is distilled off and the residue dried at 100° C. and weighed. A portion of this residue is then heated with 4–5 cc. of acetic anhydride in a flask connected with an upright condenser for one hour, whereby the melissyl alcohol of the bees'-wax is converted into the acetyl ester, which is soluble in hot glacial acetic acid. To determine the proportion of the melissyl soluble in acetic acid, the mixture, after treatment with acetic anhydride, is transferred to a 10 cc. graduated glass tube; the glacial acetic acid is next added up to about the 9 cc. mark on the tube, which is then heated on the water-bath to 90° C., corked, well shaken, and again placed in the water-bath. After standing some time the volume of insoluble matter floating on the acid is read off and calculated as paraffin (1 gm. paraffin = 1.35–1.40 cc.). This weight deducted from the weight of the residue from the chloroform extract gives the weight of the melissyl alcohol of the bees'-wax. The portion of the saponified mixture obtained as above, which is insoluble in chloroform, consists of the soaps obtained from the stearic acid, the stearin, and the cerotic acid of the bees'-wax. To determine the stearin the mixture is dissolved in hot water, filtered from the silica and asbestos previously added, and the filtrate treated with a slight excess of dilute nitric acid, which separates the fatty acids present. These are filtered off and the glycerol (originally combined with the stearin) determined in the filtrate, after neutralising the latter and precipitating with lead acetate, by means of potassium bichromate. From the quantity of glycerol found, that of the stearin can be readily calculated. Finally the cerotic acid is taken by difference.—C. A. K.

Adulteration and Analysis of Bees'-wax. A. and P. Buisine. Bull. Soc. Chim. 1891, 5, 651–660. (See also this Journal, 1891, 52–53.)

THE substances most frequently employed for the adulteration of bees'-wax are paraffins, fossil waxes, ceresine (a fossil wax purified by treatment with sulphuric acid and subsequent distillation with superheated steam) and vegetable waxes, such as those of Carnauba, Japan, and China; stearic acid, suet, wax, or waxy acids extracted from the grease of the "suint" or sweat of sheep, rosin, and organic or mineral powders are also sometimes used. Mixtures of the substances named above are also employed, and so cleverly, that adulteration is difficult or impossible to detect by the usual methods of analysis, namely, those proposed by Becker, Hehner, and Hubl, which depend on a determination of the free and combined fatty acids in the sample. If, for example, a mixture of 9.48 parts of stearic acid, 38.84 parts of suet, and 53.68 parts of paraffin is used, the results of analysis as regards the fatty acids are identical with those obtained in the case of pure bees'-wax. It is necessary, therefore, to adopt other means for the detection of adulteration, and, in addition to the determination of the fatty acids, to estimate the iodine value, and the percentage of alcohols and hydrocarbons; although the results obtained in this way with different samples of pure bees'-wax are variable within certain limits, the complete analysis gives data sufficient for the detection and estimation of any added impurity when the properties of the latter have been previously determined.

In the following table the results of an examination of the most common adulterants of bees'-wax are given; the methods employed were the same as those previously described in the case of yellow and bleached bees'-wax (Bull. Soc. Chim. 3, 867, and 4, 165; this Journal, 1891, 52–53).

Column I. gives the melting point of the substance.

Column II. gives the quantity of acids soluble in water, column III. the quantity of free acids, and column IV. the total quantity of acids contained in 1 gm. of the substance; the results are expressed in mgrms. of KOH.

Column V. gives the quantity of iodine fixed by 100 parts of the substance, column VI. the volume of hydrogen in cc. (measured at 0° and 760°) evolved from 1 gm. of the substance on treatment with potash, and column VII. the percentage of hydrocarbons.

By comparing the results of the analysis of the sample of bees'-wax with those given in the above table the nature of the added impurities can be determined; the composition of the mixture can then be calculated on the basis of the values given above, and the analysis verified by comparing these numbers with those determined experimentally.

—F. S. K.

Method of Determining Indigotine for Commercial Purposes.

F. A. Owen. J. Amer. Chem. Soc. 1891, 13, 32–33.

ABOUT 2 or 3 grms. of the sample are shaved off and coarsely powdered, and from this quantity 2 portions of 1 gm. each are accurately weighed out. In one of these determine the moisture by drying at 100° on a watch glass, and use the residue for the determination of the ash. The second portion is finely ground and then triturated several times in a glass mortar, and the whole transferred to 200 cc. flask. 3 grms. of zinc-dust and 60 cc. of ammonia (concentrated) are added, the flask then filled up with water to 1 cc. above the 200 cc. mark and shaken. From half an hour to 2 hours is required for the reduction, during which period the shaking of the flask is continued at intervals. When the reduction is complete the froth will subside and the solution will become pale yellow, or with some samples which contain chlorophyll or other non-reducible green colouring matter, greenish-yellow. 50 cc.

of the solution are then removed by a pipette from the flask to a beaker, or porcelain dish, 5 or 6 drops of ether added and the whole agitated by blowing air through the pipette. The precipitated indigotine is acidified with hydrochloric acid, heated to boiling and collected on a tared filter-paper. Finally it is dried at 100° C. and weighed. The results are accurate, and it is not necessary to take any special precautions to prevent the absorption of moisture by the precipitate during the weighing. Lots when bought and retested should show no variation from the sample, except in the percentage of moisture, which will be higher than in the sample. Indigo often loses 20 per cent. on drying, and yields as much as 80 per cent. of indigotine on the dried sample.—C. A. K.

ANALYTICAL AND SCIENTIFIC NOTES.

On the Intensity of Transmitted Light when the Co-efficient of Transmission of the Medium is a Function of Time. Jas. Bottomley, Mem. and Proc. of the Manchester Literary and Phil. Soc. **4**, 1890—1891.

A recently mathematical treatise, in which, however, at its close the author observes that "the subject of his paper manifestly admits of several practical applications, as for instance *inter alia*, the quantitative determination of colouring matter undergoing change, in cases where the balance could not be used on account of the minute quantity of the body to be estimated, or on account of its instability."

Action of Sunlight on Organic Compounds. H. Klinger and O. Standke. Ber. **24**, 1340—1346.

The Action of Running Water on Certain Minerals. J. Thoulet. Compt. Rend. **112**, 502—503.

THE loss of weight of calcareous minerals on exposure to the action of water, is much greater in the case of running, than in that of stagnant water. The author agrees with the theories of Mohr, and John Murray and Irvine, regarding the absence of limestone in the ocean depths.—E. B.

On the Use of Liquid Carbonic Acid for the Rapid Filtration and Sterilisation of Organic Liquids. A. D'Arsonval. Compt. Rend. **112**, 667—669.

See under XVII., page 717.

Action of Certain Reducing Agents on Sulphur and Selenium. E. Trautmann. Bull. Soc. Ind. Mulhouse, 1891, 87—88.

AN odour of hydrogen sulphide manifested itself on acting with tin and hydrochloric acid on an alcoholic solution of an aromatic nitro-compound which had been accidentally mixed with finely-divided sulphur; when the product of the reaction was poured into excess of water, a precipitate of stannous sulphide was produced. As the sulphur in question had been precipitated by acid from yellow ammonium sulphide, the presence of sulphurous acid was

excluded, and the inference is, therefore, that hydrogen sulphide is produced by the action of nascent hydrogen on an alcoholic solution of sulphur.

Pursuing the subject, the author finds that in the presence of glacial acetic acid, a mixture of pure sulphur, tin, and hydrochloric acid, gives a more abundant yield of hydrogen sulphide than the same mixture in the presence of alcohol, and that, provided the sulphur be very finely divided, the gas is disengaged in small quantity, even in the absence of an organic solvent; moreover, a solution of stannous chloride in hydrochloric acid has a feeble action on sulphur. An acetic acid solution of sulphur also evolves hydrogen sulphide on treatment with zinc.

Selenium behaves similarly to sulphur in the above reactions.—E. B.

The Ferment-Action of Bacteria. T. L. Brunton and A. Macfadyen. Proc. Roy. Soc. **46**, 542—553.

THE experiments show that bacteria which liquify gelatin do so by means of a soluble enzyme which is capable of withstanding a slightly higher temperature than the bacteria themselves. By precipitating liquefied gelatin by alcohol, a precipitate was obtained which possessed the power of liquefying gelatin. A more active preparation was obtained in a similar manner from meat broth in which the bacteria had been cultivated. Acidity hinders, alkalinity favours the action of this enzyme. When the bacteria are grown in a solution containing starch, they secrete a diastatic enzyme which is quite distinct from the enzyme which liquefies gelatin. They will also grow in solutions of dextrose, and will disintegrate muscle, but will not grow in solutions of cane sugar or have any effect on fats.—A. L. S.

The Borderland between Physics and Chemistry. G. F. Barker. J. Amer. Chem. Soc. 1891, **13**, 11—29.

A PRESIDENTIAL address to the American Chemical Society.—C. A. K.

Alteration of the Density of Water on Heating. D. Mendeleeff. J. Russ. Chem. Soc. **23**, 183; J. Russ. Chem. Soc. 1884, 7; J. Chem. Soc. (Trans.) 1884.

THE expansion of water on rising the temperature of heating, in spite of its great scientific and practical importance, cannot be considered either theoretically fully explained or practically exhausted. All the existing determinations after all necessary but not sufficiently exact corrections, differ much too widely to be considered sufficient at the present state of scientific measurements and weighing up to the millionths.

Although this communication of the author, being the result of his working over the existing data on the subject, and forming but preliminary remarks, to be followed by his own experimental investigation, yet he proposes a new equation covering all that is known concerning the density of water. It is this:

$$S_t = 1 - \frac{(1 - 4)^2}{(A + t)(B - t)C}$$

A, B, and C being constants whose exact amounts hardly can be found on account of the want of exactness in the usual corrections. (For instance, the co-efficient of expansion of mercury and glass is considered constant, while this is not the case.)

In three elaborate tables the author shows:—

I. The existing data concerning the density of water by 13 different investigators.

II. Averages of the above data.

III. The author's figures calculated by means of his formula.

The principal data of the three are condensed into one table as follows:—

t° C.	Average of all existing Data on the Density of Water on Heating.	Volumes Calculated by Means of Mendeleeff's Formula, v_p .	Calculated Sp. Gr. of Water, s_p .	Possible Errors of Modern Determinations in Millionths.

PATENTS.

An Improved Stand for Chemical or other Purposes.
A. W. Ellis, London. Eng. Pat. 3187, February 21,
1891. 8d.

AN outer tube is fitted over the upright rod of the retort stand. The rings, &c., are clamped upon this tube, and the tube can be raised or lowered and held in any desired position by a collar and set-screw. The advantage of the contrivance is that when the rings have once been arranged as desired, the retort or other apparatus upon them can be raised or lowered by one movement instead of having to readjust each ring separately. Various modifications of the contrivance are described.—H. S. P.

Improvements in Centrifugal Apparatus for Testing the Composition of Milk and other Compound Fluids.

Trade Report.

(From the Board of Trade and other Journals.)

TARIFF CHANGES AND CUSTOMS REGULATIONS.

GREAT BRITAIN AND IRELAND.

General Order as to Methylated Spirit.

Inland Revenue, Somerset House,
London, W.C., 20th July 1891.

Ordered—

That the attention of the officers of the Department be directed to the following regulations which are to be observed with regard to the preparation of methylated spirits for sale by retailers :—

1. An authorised methylator must in the presence of the proper officer of Inland Revenue mix with and dissolve in all methylated spirits, to be supplied to a retailer of methylated spirits for sale by him, a quantity not less than three-eighths of 1 per centum by volume of mineral naphtha of a specific gravity of not less than 800. The mineral naphtha must before the mixing thereof be approved by the Board, samples being taken and dealt with as directed in Licence Instructions, page 69, paragraph 4.

New forms of requisitions have been prepared for obtaining methylated spirits for sale by retailers, and supervisors should apply to the Controller of Stamps and Stores for a proper supply.

2. Essential oil or other flavouring matter must not, without the express sanction of the Commissioners of Inland Revenue, be added to or mixed with methylated spirits.

3. A retailer of methylated spirits must not sell or have upon his premises for sale methylated spirits containing any essential oil or other flavouring matter, or in which mineral naphtha has not been dissolved.

4. In any case where methylated spirit for sale by retail is supposed from its odour to contain essential oil or other flavouring matter, or where the spirit, by remaining clear when diluted with water, shows the absence of mineral naphtha, a sample should be forwarded to the laboratory under the usual regulations.

5. A person who has been authorised to *receive* methylated spirits for *use* in any art or manufacture carried on by him, whether he holds or does not hold a licence as a retailer of methylated spirits, must obtain all methylated spirits from an authorised methylator only, and in the manner directed by sub-section 4 of section 124 of Spirits Act, 1880.

6. When in any case it is, from local circumstances, deemed desirable that an account should be kept by a retailer of methylated spirits in accordance with the terms of the 126th section of 43 & 44 Vict. c. 24., the supervisor should at once report the circumstances, and, if enjoined, the account should be in the following form:—

METHYLATED SPIRIT RETAILER'S STOCK ACCOUNT.

[illegible]

The present stocks of ordinary methylated spirits for sale by retail should be disposed of before the 1st January 1892. The other regulations specified are to be in force from the 1st September 1891.

A copy of this order should be delivered to every authorised methylator and every retailer of methylated spirits, and a memorandum must be entered of such delivery in the store and general register of the station.*

RUSSIA.

New Customs Tariff.

Sir R. B. D. Morier, Her Majesty's Ambassador at St. Petersburg, in a despatch to the Foreign Office, dated the 9th July, encloses a French translation, as published in the *Journal de St. Petersburg*, of an article which has appeared in the "Ministry of Finance Gazette," on the new Russian tariff (see below).

The article points out that in the tariff of 1869, ultra-protection was abandoned for moderate protection, which favoured the importation of manufactured goods; since then partial measures of a protective character had to be resorted to, so as to protect national industries, which were in the first phases of development, against foreign competition; and, in addition to these measures, the law making it obligatory to pay all Customs duties in gold raised the import duties by 30 per cent. in 1877, by 10 per cent. in 1881, and by 10 per cent. to 20 per cent. on most articles in 1885.

This gradual return to the system of ultra protection has greatly contributed towards the development of the manufacturing industries of Russia, which, producing only 217,900,000 roubles in 1867, increased to 316,900,000 roubles in 1876, and amounted to 562,300,000 roubles in 1888. This production is distributed as follows among the different branches of industry:—

	1867.	1876.	1888.	Increase of 1888 over 1876.
	Millions of R.	Millions of R.	Millions of R.	Per Cent. 1868.
Cotton yarns and tissues	72.6	102.7	253.5	146.8
Woollen yarns and tissues	49.2	55.5	68.1	23.2
Dye works, cloth-printing works, &c.	32.0	37.7	73.6	95.2
Flax and hemp yarns ...	15.0	20.1	29.2	45.2
Silk industry	4.3	8.2	12.1	51.2
Paper making, wall- paper, &c.	5.3	9.8	16.2	56.3
Chemical products and dyestuffs	4.6	5.5	15.6	183.6
Leathers, &c.	16.1	26.6	31.2	28.6
Articles of glass, crystal, &c.	3.5	5.2	9.0	73.0
Lacquered porcelain ...	4.3	2.2	1.0	81.8
Machinery production ...	11.0	44.1	106.9	67.5

The article then continues with the statement that, on the other hand, the gradual increase of the duties reduced the imports from 112,561,000 credit roubles in 1876 to 329,930,000 roubles in 1888.

The *Board of Trade Journal* for August (pp. 118—165) also contains a statement of the import duties now leviable in Russia on the principal articles of British produce or manufacture. This tariff came into force on the 13th July 1891.

The following classification has been adopted:—Yarn and threads, woven manufactures, metals (unwrought and wrought), earthenware and porcelain, glass and glasswares, hides, skins and leather (unwrought and wrought), india-

rubber and gutta-percha, paper, &c., chemicals, salt, oils, minerals, &c., articles of food, and miscellaneous articles.

The following is a statement of the duties now leviable upon chemicals:—

Tariff Classification.	Tariff Rates of Duty.	English Equivalent.
CHEMICALS:		
<i>Alkali:</i>		
Carbonate of soda and carbonate of potash.	Rbbs. cop. Pond 0.55	Cwt. £ s. d. 0 5 5

SWITZERLAND.

Classification of Articles in Customs Tariff.

Note.—Quintal = 220 1 lb. avoirdupois. Franc = 9¹⁰/₁₀₀d.

The following decisions affecting the classification of articles in the Swiss Customs tariff were given by the Swiss Customs authorities in the months of May and June last:—

Paper chemically prepared for photography.—Category 270a. Duty, 16 francs per quintal.

Steatite of sulphate of copper (for checking the diseases of the vine and potatoes), a powder composed of about 50 per cent. of soapstone and 10 per cent. of sulphate of copper (vitriol).—Category 16. Duty, 30 cents. per quintal.

Antikampine (derived from tar, used for the destruction of worms and caterpillars).—Category 16. Duty, 30 cents. per quintal.

Cable grease (mixture of greases and graphite used for putting round cords, cables of iron wire, electric cables, &c.).—Category 18. Duty, 2 francs per quintal.

ITALY.

Customs Duties on Mineral Oils.

Note.—Quintal = 220 1 lb. avoirdupois. Franc = 9¹⁰/₁₀₀d.

Mr. H. N. Dering, Her Majesty's Commercial Attaché at Rome, in a despatch to the Foreign Office, dated the

* From correspondence between the Chairman of the London Section and the Inland Revenue, we can state that this order will not affect those authorised users of methylated spirit for manufacturing purposes who also hold a retailer's licence, to whom stock of both kinds is permitted.

24th July, forwards copy and translation of a law which has recently been passed by the Italian Parliament, and which has been published in the *Official Gazette*, modifying the tariff for mineral oils and regulating their classification for Customs purposes. According to this law, the duty on heavy mineral, resin, and tar oils is fixed at 8 francs per quintal, and on other kinds at 47 francs per quintal.

TUNIS.

Tariff Changes.

Mr. R. Drummond-Hay, Her Majesty's Consul at Tunis, in a report to the Foreign Office, dated the 6th July, encloses copy of a Beylical decree of the 23rd June 1891, published in the *Journal Officiel Tunisien* of the 2nd July, removing the prohibition on the importation into Tunis of nitrate of soda, sulphur, and saltpetre, and specifying the articles included in that category, which will be exempted from duty if imported for agricultural purposes and for the treatment of diseases of the vine. The following are the articles so exempted:—

Guanos, phosphates, and superphosphates, bone powder, phosphated gypsum, horn manures, fish manures, metalurgical phosphates, dried blood, burnt leather, sulphate of ammonia, sulphate of potash, sulphate of iron, nitrate of potash, nitrate of soda, chloride of potassium, chemically composed manures, sulphur sublimate, triturated sulphur, sulphate of copper, nicotine, ammoniate of copper, sulphuric acid, ammonia, and powders and liquids used in the treatment of diseases of the vine.

THE BAHAMAS.

Tariff Changes.

By Ordinance No. 7 of 1891, tallow, rosin, caustic soda, potash, palm oil, electrical apparatus and appliances, metal roofing, and crude petroleum are added to the free list, and a drawback of 90 per cent. of Customs duty is allowed on kerosene oil used as fuel in the working of steam engines.

GENERAL TRADE NOTES.

THE USES OF PEAT IN THE ARTS AND INDUSTRIES.

The *Handels Museum* of 16th July publishes an extract from an article by Dr. Leo Pribyl, who maintains that peat is a valuable raw material, the uses of which, except as fuel and litter, are as yet very limited. The fibre is unsurpassed as a packing material for use in the case of breakable merchandise, being much superior to straw, hay, &c., owing to its greater elasticity and dryness. In the case of consignments consisting of liquids, it possesses the advantage of being peculiarly adapted for absorbing any of the contents which may have escaped through breakage, and thus preventing damage which might result to other consignments through damp. In the shape of dust and litter it is especially adapted for preserving perishable articles. Meat when packed in it will keep fresh for weeks, and will eventually dry up, the moisture being absorbed by the peat. In this way fresh sea fish has been sent from Trieste to Copenhagen, and has reached its destination in perfect condition. Peat is also successfully used for preserving fresh fruit; even grapes may be made to retain their fresh appearance for months, and, owing to the high prices of this fruit in spring and summer, would amply repay the trifling expense incurred by the use of peat dust. Experiments have shown equally satisfactory results in the case of pears, apples, plums, &c., as also in the case of cabbage, turnips, and potatoes, peat packing having the advantage, not observable with other packing materials, of preventing the sprouting of potatoes in spring. The question as to the best method of preserving eggs for the winter months is an important one, and still remains without any satisfactory answer. Possibly the preservative qualities of peat might here again be illustrated, and a satisfactory solution of this important question be arrived at.

It has been found a drawback in the use of artificial saline manure that in wet weather it forms itself into hard lumps which cannot be scattered by the manure spreading machines, a difficulty which may be obviated by the use of a small quantity (2.5 per cent. has been found to be sufficient in the case of kainite) of peat dust with the manuring salt.

As a substitute for ashes and straw in filling up the partition walls of cellars and ice-house broken peat is most suitable, as the effect of moisture on the ashes or straw is such as to render their immediate removal a necessary condition for the continued use of such places. Ice has been preserved for eight days in a cement barrel when covered with dry peat litter. Two pieces of ice were exposed to the sun's rays in Braunschweig, one of them was covered with wood shavings, and the other with a layer of equal depth of peat litter. The former had thawed in 72 hours, when it was found that the latter was still almost entire. From this it is seen that peat is a bad conductor of heat, and is consequently well adapted for isolating purposes.

Peat dust has been recommended as an excellent ingredient for use in the manufacture of light porous bricks, being mixed with the clay previously to baking. Bricks of this kind are much sought after in certain branches of architecture. But still further industrial uses are found for peat. The peat bogs of Northern Germany and of Sweden are being worked by joint stock companies with a view to obtaining the elastic fibre which, when free from dust, is used for weaving into carpets and other textile fabrics. Considerable capital is invested in these undertakings in Oldenburg and Sweden. The paper industry too, in the manufacture of peat cellulose, has shown a decided preference for this tender and pliant fibre, so that it may be justly said that at the present time the supply of good peat is inadequate to meet the demand, considering the varied uses of this unpretentious raw material.

The chemical industry is using peat in the manufacture of charcoal, peat-coke, peat-gas, &c., thus converting a cheap raw material into a valuable industrial product. Boghead-naphtha, tar, solar oil, paraffin, acetic acid, and gas have been produced from peat, and it has even been used in tanning. It has been for years used in Germany for absorbing waste liquids and refuse in factories, and in this way has furnished large quantities of valuable manure in certain districts.

An enumeration of the manifold uses of peat will prove that this raw material, which has hitherto been considered of little importance, and which nature has provided in such abundance, even if it be in many districts partially distributed, is destined not only to benefit agriculture by its valuable properties and chemical composition, but to lay the foundation of a flourishing and wide spread industry. A new era has been entered upon in the sanitation of towns by using peat, and it is to be hoped that advantage will be taken of the undoubted benefit arising from its use both as regards the health of urban populations and the promotion of agricultural interests by the supply of large quantities of manure. In this way extensive and unproductive tracts of bog land would be converted into valuable properties, and a flourishing industry would provide work and wages for thousands of hands.

THE NETHERLANDS MARGARINE TRADE.

In a report dealing principally with the trade in American oleo oil as a material for the manufacture of margarine in the Netherlands, the United States Consul at Rotterdam writes as follows:—

Oleo oil of the value of 10,000,000 dollars was imported into the Netherlands from the United States during the calendar year 1890. It was purchased by the makers of Dutch "margarine" (substitute butter) whose present consumption of American oil exceeds by more than 100 per cent. the consumption of five years ago.

Other European countries sending oleo oil to this foremost margarine market of the world are England, France, and Austria. These supply only 20 per cent. of the whole, however, the remaining 80 per cent. coming from the United States; and the oleo products of these European

countries, in comparison with the American product, is distinctly inferior in quality and price.

From 1886 to the close of 1890 the prices of oleo oil in the Netherlands markets tended steadily downward, the range being from 100 to 112 florins per 100 kilogrammes (18 to 21 cents per pound) in 1885—86 down to 45 to 50 florins per 100 kilogrammes (8 to 11 cents per pound) in 1890. Within the present calendar year, there has been a marked and sustained rise owing to depleted stocks.

The chief city of export of oleo oil in the United States is Chicago. During 1890 it sent to this market quite 60,000,000 lbs., or more than one-half of the total American supply. Other export cities of importance are New York, Philadelphia, Omaha, Kansas City, and Boston.

The trade in American oleo oil for the Netherlands centres in Rotterdam. There are in this city eight importers and 15 brokers dealing exclusively in the product. One of the great Chicago packers has here his own representative sent from Chicago, while the others are represented by resident firms of established standing and reputation.

The large margarine factories in the Netherlands number 32. In Rotterdam, 5; Oss, 4; Nymwegen, 4; Bois le Duc, 3; Haarlem, 2; Helmond, 2; and in Dordrecht, Grooterhout, Asten, Alkmaar, Amsterdam, Waspik, Zwammerdam, Gouda, the Hague, Middelburg, Oldenzaal, and Weesp, 1 each.

These factories differ greatly in size, capacity, and value. All, however, are modern in equipment, and those more recently built represent large investments, proving the faith of their Dutch owners in the future of margarine. One plant lately erected in Rotterdam cost 500,000 guilders (200,000 dollars), and ranked among the imposing structures of the city.

Possibly the most representative among margarine factories of the Netherlands is one situated at Oss, in the province of North Brabant. It is owned and operated by Anton Jurgens, whose family through four successive generations have made butter on the site of the present factory. The buildings and grounds are extensive, the machinery employed is ingenious, efficient, and costly, and from end to end the establishment is a marvel of Dutch orderliness and cleanliness.

This factory produces and ships regularly 25 tons of margarine per week. It gives steady employment to 200 heads of families, many of whom are expert workmen. It consumes each week an average of 125,000 litres of milk, the yield of 10,500 cows owned by 2,000 small farmers living in the adjacent country districts.

The little city of Oss has 6,000 inhabitants. It has four margarine factories, but no other industry of note. Directly or indirectly its 6,000 people, as also the majority of the farmer folk for miles around, get their very comfortable living out of the margarine industry, which has become, here, as elsewhere, in Holland, a permanent local benefice.

The above reported increase of oleo oil imports into the Netherlands of more than 600 per cent., within five years, indicates a corresponding increase in the exports of margarine. The factories here are employed chiefly in supplying a foreign demand, the estimated home consumption of margarine being only 10 per cent. of the total output.

Statistics relating to margarine exports are, however, unobtainable. There are, so far as I am able to learn, no records of value for purposes of comparison, either public or private. Commercial statistics in the Netherlands are kept but indifferently well at best, and as to margarine, until the enforcement in January 1890 of the national law requiring all margarine to be branded, it had uniformly been classified with other dairy products, never separately.

Experts in the trade agree that the present exports are considerably more than twice as large as those of five years ago, and that the foreign market is steadily increasing.

The countries principally purchasing the Netherlands margarine are Great Britain, Belgium, and Germany, countries, it is significant to note, whose cities, above all other cities of Europe, teem with workpeople earning small wages, to whom cheap food is essential.

The glimpse thus afforded of the growth and present extent of a permanent and valuable industry of the Netherlands, which had its exceedingly unpopular beginning less than 20 years ago, suggests a glance at the cause of such growth and at the methods whereby it has been attained.

The step preliminary to the manufacture of margarine in the Netherlands was the adulteration of cream butter. In 1872—74 the world-famed Holland dairies, in sharp competition with the butter makers of other countries, began to employ syrup and glucose for enlarging and cheapening their product. The adulteration increased from 10 to 25 per cent., then to 50 per cent. As the proportion of new ingredients grew, the necessity for substances absolutely wholesome became imperative.

Repeated and expensive experiments under widely varying conditions proved oleo oil to be possessed of actual and high merits as a food substance, and it was a matter of course—oleo being in far larger supply than the cream of the dairy—that the animal oil should succeed speedily to the place of the chief ingredient.

Substitute butter from oleo oil, manufactured by approved methods, is a food article of demonstrated merit, and has come to stay, so far at least as European countries are concerned. It cannot be legislated out of existence. By legislation its production cannot even be greatly restricted. Attempts in this direction avail nothing on behalf of the farmer, and directly injure the armies of wage-earners in cities who need cheap wholesome food. Legislation can compel the margarine to be branded and sold for what it really is, thus benefiting the honest manufacturer not less than the consumer; but at that point legislation in the Netherlands has been wisely content to stop.*

Farmers in the Netherlands who own cows and have hitherto made butter have been forced to admit, as a result of experience, that the manufacture or sale of substitute butter, though ever so extensive, does not appreciably injure farm profits. If one be a large farmer with good dairy facilities and able to produce good dairy butter, he finds now a more exclusive market and better prices than in the days when every owner of a cow made butter. If, however, one lack facilities for the best butter making, and if one be owner of a few cows, he is able to command at the margarine factory an established all-the-year-round price for his milk that yields larger net profits than did the erstwhile sale of his indifferent butter. Large dealers, also, who formerly conducted trade in butter, find the present business in margarine no less profitable.

Consciously or ignorantly, in European countries and, I think, also in the United States, a very large percentage of the less well-to-do people must eat substitute butter. I have official statistics before me as I write which show, after a trifle computation, that if all the milk of all the cows in Great Britain were devoted to butter making, the utmost possible average product of a year would be just 4 oz. per head of the population. European workpeople conclude thus, that it is for them, to a very considerable extent, a matter of substitute butter or no butter food whatever. They conclude also, as the fast increasing sales of margarine abundantly prove, that the cleanly, healthful, nutritious substitute made by known and reputable manufacturers is far preferable to doubtful butter of unknown composition and origin.

In the calendar year 1885 the estimated total output of Netherlands margarine (the finished butter product) was 92,400,000 American pounds; in the calendar year 1890 the estimated total was 165,000,000 pounds, an increase in the annual output within five years of 72,600,000 pounds. Of the above given total product for the year 1890, it is estimated that 127,600,000 pounds were exported, while only 37,400,000 pounds went into home consumption.

The foreign countries to which Netherlands margarine is at present exported are, in the order of their importance as margarine buyers, England, Belgium, France, Spain, Portugal, Sweden, Norway, Denmark, the Transvaal, and the Dutch, English, and Portuguese colonial possessions.

* The law of the Netherlands permits oleo oil (the raw material) to enter duty free, thus giving to the margarine industry a positive encouragement.

At the present time, seven-tenths of all the oleo oil (the raw material) used in the manufacture of margarine in the Netherlands comes from the United States.

PRODUCTION OF SULPHUR IN ITALY.

In a recent report the French Consular Agent at Bologna supplies the following particulars of the production of sulphur in Italy, and specially in the Province of Romagna:—

It is estimated that in 1850 Sicily supplied about 500,000 quintals of sulphur annually, and that was sufficient for the needs of Europe, for war and industry. Agriculture has also required this commodity largely, and whilst in face of constantly growing demands, Sicily multiplied its production, and since 1855 the deposits situated at the extremity of Romagna, towards Montefeltro, have been worked. In 1878, the Sicilian production amounted to 2,500,000 quintals, and the Romagna production to 500,000 quintals, together 3,000,000 quintals of raw sulphur valued at 1,200,000*l.*, or 8*s.* per quintal on an average, but a little less in Sicily and a little more in Romagna. This price was a reduced one by reason of the excess of production, for a few years back raw sulphur was worth more than 11*s.* in Sicily and as much as 13*s.* in Romagna.

The demands of North America have absorbed the surplus production, and the prices amounted to 10*s.* (Romagna, 1884), falling to 8*s.* in 1885, and dropping as low as 6*s.* 6*d.* in 1889 and on the 1st September 1890. It may safely be affirmed that below 8*s.* all the workings were carried on at a loss in the Romagna district; several were suspended and the production was reduced to 200,000 quintals in 1886. It has since further diminished, but statistics are not forthcoming for a more recent date.

Romagna was first affected by the fall in prices, because its production is the most costly. Notwithstanding the employment of machines and horses, its deeper deposits entail more labour than the Sicilian, and at a greater cost, one reason being that children must not be employed.

The greater part of the capital sunk has been lost. Many of the workmen have emigrated, and, in order to give employment to a few others, in certain places they have been allowed to do piece-work, two-thirds of the ore extracted being given up to them. The refiners have obtained the sulphur from Sicily in order to make up for the dearth of local extraction, and to keep their works going.

Sicily has experienced still lower prices (5*s.* 6*d.* per quintal of raw sulphur in 1889), and it has resisted hitherto the relative exhaustion of its sulphur mines; but at present its production does not equal the demand. According to the Customs statistics, the maximum of working was reached in 1889 and amounted to 3,319,016 quintals of raw or refined sulphur. The export was 3,287,081 quintals, of which 1,107,672 were despatched during the first quarter. But, during the first quarter of 1891, there were only exported 736,378 quintals from Italy. This falling off is entirely due to the scarcity of the commodity, and not to a smaller demand, for the price of raw sulphur has risen higher than in 1884, and bids fair to exceed the prices of 1874; the price-list of the Bologna Exchange gives it at 11*s.*, but at Romagna it is stated to be 13*s.*, that is to say, double the price of last year. The result has been a great revival in this industry among the owners of mines from Forti to Fossombrone, but what seriously affects it is the absence of capital.

MINERAL DISCOVERY IN MYTELENE.

A correspondent of the *Journal de la Chambre de Commerce de Constantinople* writes from Mytelene (the capital of the island of the same name) that a mineral has been discovered in the district of Plomari having the properties of talc. A chemist, who has pursued his studies in France, has erected a small establishment for the preparation of this product, and the first trials have been more or less successful, and this mineral, existing in large quantities at several places in the island, may one day supplant talc, which will largely affect the imports from Genoa, which annually amount to about 2,000,000 kilogrammes of talc.

THE MINERAL PRODUCTION OF ITALY IN 1889.

The total production of Italian mines in 1889, according to *Industries*, shows an increase of 38,240 tons over 1888, valued at about 230,000 dollars, an increase of 3·13 per cent. in quantity and 2·19 per cent. in value. The production of 1888 compared with that of 1887 showed an increase of 1 per cent. in quantity and 4·6 per cent. in value. The increase in 1889, both as regards quantity and value, is mainly due, in order of importance, to the larger production of zinc ores, mercury, coals, lead ores, iron pyrites, asphaltum, and bitumen, antimony, and auriferous ores. The decrease occurred mainly in sulphur, copper ores (only in value), silver ores, iron ores, salt, and boric acid. The following table shows the production of Italian mines in 1889:—

Products.	No. mines worked.	Production.		No. of Men employed.
		Quantity.	Total value.	
		Tons.	Lire.*	
Iron ores	43	173,189	1,887,231	1,418
Manganese ore	5	2,203	51,804	46
Copper ores	16	48,214	1,341,528	1,300
Zinc ores	102	97,059	8,257,775	10,587
Lead ores		36,894	7,002,348	
Silver ores		1,997	1,718,663	
Gold ores	20	10,932	598,427	451
Antimony ores	5	563	100,072	328
Mercury (metal)	9	385	2,274,450	533
Iron pyrites	4	17,022	216,494	343
Coals	37	340,320	2,858,154	2,714
Sulphur	119	371,494	21,652,876	20,028
Salt	19	28,490	556,633	635
Asphalt, bitumen, and petroleum, also mineral waters.	28	33,521	620,532	996
Aluminite	1	5,900	110,000	76
Boric acid	11	2,473	1,236,550	49
Graphite	7	1,531	10,271	27
Total	726	1,222,187	53,553,805	48,581

* One lire is equivalent to 19·3 cents.

The following table shows the production of metallurgical and chemical works in Italy in the year 1889:—

Products.	No. of Works.	Production.		No. of Men employed.
		Quantity.	Total Value.	
		Tons.	Lire.	
Pig iron	11	53,473	2,123,096	227
Iron and steel	323	181,623	50,343,398	14,518
Gold	3	212	569,848	89
Lead	1	18	6,176,100	700
Silver		23	5,025,750

Salt.....	119,115
Asphalt.....	1,825
Boric acid.....	1,943
Graphite.....	1,376
Mercury.....	394

PRODUCTION OF ALUMINIUM IN THE UNITED STATES.

The Cowles process, now carried on by the Cowles Electric Smelting and Aluminium Company at Lockport, N.Y., which was the pioneer of electro-metallurgical processes for the reduction of aluminium, was established in 1885. Since that time its production has been as follows: aluminium bronze, 1885, 1,000 to 5,000 lb., valued at 1,600 to 2,000 dols.; 1886, 50,000 lb., valued at 20,000 dols.; 1887, 111,764 lb., valued at 57,000 dols. Ferro-aluminium (containing from 5 per cent. to 10 per cent. aluminium), 1886, 2,000 to 3,000 lb., valued at from 780 to 1,170 dols.; 1887, 12,617 lb., valued at 16,621 dols. The total aluminium alloys produced by this company in 1889 was 171,759 lb. The production of aluminium by the Pittsburg Reduction Company in 1889 was 19,200 lb., which was sold at 2 dols. per lb. in quantity. The total production of aluminium in the United States in 1889, including that contained in alloys, was 17,468 lb., valued at 97,335 dols.

The imports of aluminium into the United States are given in the following table:

Years.*	Quantity.	Value.	Years.*	Quantity.	Value.
	Lbs.	Dols.		Lb.	Dols.
1870	..	58.00	1880	310,775	1,012,000
1871	..	111.00	1881	517,710	6,074,000
1872	1882	569,750	6,195,000
1873	*2,000	..	1883	429,275	5,079,000
1874	*684.00	*1,175.00	1884	325.00	8,116,000
1875	*131,000	1,355.00	1885	139,000	1,736,000
1876	119,000	1,412,000	1886	132,000	5,369,000
1877	131,000	1,754,000	1887	1,260,000	12,419,000
1878	251,000	2,378,000	1888	1,148,331	14,086,000
1879	281,141	3,123,000	1889	998,881	6,688,000

* Probably alloys.

* Fiscal years ending June 30th to 1886; calendar years subsequently.

France was the only country which produced aluminium commercially until a few years ago. It had never been seen in any quantity until the Paris Exposition of 1855, where it was shown in ingots and in the form of manufactured articles of various kinds. Among ornamental articles it was noticed that a small body of the Imperial Guard wore breastplates of aluminium. The price of the metal was then 2,000 francs a kilo. The production was as follows: 1863, 1 ton; 1867, 1.7 tons; 1872, 1.8 tons. Later statistics give the aluminium product of France as follows: 1886, 2,430 tons, valued at 243,000 francs; 1887, 2,040 kilos., valued at 204,200 francs; 1888, 2,955 kilos., valued at 295,500 francs. Allowing the French production to have been 1.5 tons a year from 1860 to 1880 and 2.5 tons from that to 1889, inclusive, we should have $31.5 + 22.5 = 54$ tons, or about 60 short tons, in the 30 years.

The production of aluminium in England in 1888 was 5,000 lb., valued at 5,000/; in 1889, 12,000 lb., valued at 6,000/.. There was an English manufacture of aluminium from about 1860 to 1874, but no statistics of its production are obtainable. It could not have been very considerable, as the price of the metal was then very high. The Castner process was inaugurated in England in 1888. Supposing 5,000 lb. per annum to represent the English production from 1883, when the Webster process was put in operation, to 1888, we have 30,000 lb. which, with the 12,000 lb. for 1889, equalling 42,000 lb., or 21 tons, may be regarded as the English production up to the beginning of 1890. The French and English production would therefore amount to about 82 tons. The Aluminium and Magnesium Fabrik, at Hemelingen, near Bremen, has been in operation since the latter part of 1887, and has supplied all the aluminium produced in Germany. The production of this country is given as follows: 1887, 1,700 kilos.; 1888, 8,400 kilos.; 1889, 9,500 kilos.; total, 19,600 kilos.

Adding this total to the figures representing the sum of the French, English, and the American production from all sources, exclusive of alloys, which is nearly 94 short tons, we get in round numbers, 116 short tons, which therefore represents the total production of aluminium from 1860 to 1889, inclusive.

PRODUCTION OF OZOKERITE IN THE UNITED STATES.*

Ozokerite, or "mineral wax," belongs to the series of hydrocarbon compounds which include marsh gas, petroleum, and paraffin, it being very similar in appearance to the latter. It is colourless to white when pure, but frequently occurs leek-green, yellow, and brown. Prior to 1888 the only locality producing this mineral oil was in the province of Galicia, in Austria. Mining began there in 1862, and though at first it was found exceedingly difficult to obtain sufficient capital to push the enterprise, it has increased rapidly since that date, and at present there are 35 companies engaged in the industry in the province of Galicia alone. For 26 years production was limited to this locality, but in 1888 American ozokerite began to receive the attention of the trade, and considerable work was begun upon a newly discovered vein in Utah. The mineral had been known to exist in Utah for some years, but whether in paying quantity was not satisfactorily determined until August 1888.

During 1888 and 1889 most of the work was done in the way of development, but in the latter year there were incidentally produced 75,000 lb. of crude ozokerite. Of this product, 31.33 per cent. is lost in refining, the amount of refined ozokerite being 50,000 lb., valued at 2,500 dols. The product of 1888 was estimated at 65,000 lb. of crude mineral. The product for 1890 will probably exceed 300,000 lb.

Refined ozokerite is used for nearly all the purposes to which ordinary bees'-wax is applicable. It possesses nearly all the properties of bees'-wax except stickiness, but in cases where that quality is essential it is necessary only to mix the mineral with ordinary bees'-wax. Crude ozokerite, like other hydrocarbon compounds, is used to a considerable extent as an insulator for electrical wires.

* From Census Bulletin, No. 73.

The following table shows the quantity and value of crude and refined ozokerite imported into the United States from 1873 to 1889, inclusive :—

Years.	Quantity.	Value.	Years.	Quantity.	Value.
	Lb.	Dols.		Lb.	Dols.
1873	25,135	4,244	1882	272,509	29,322
1874	380	40	1883	565,658	52,774
1875	7,430	1,026	1884	617,992	69,026
1876	16,525	2,229	1885	1,036,438	123,976
1877	101,604	11,720	1886	860,406	71,220
1878	69,884	7,878	1887	718,769	59,054
1879	44,963	6,016	1888	1,164,940	89,131
1880	103,973	14,057	1889	1,078,725	86,682
1881	98,911	12,792			

AN INCREASING DEMAND FOR GRAPHITE.

The successful experiments which have been made in the use of graphite as a lining for converting vessels, it being a material specially adapted to withstand the cutting action of the acid slag, has brought about a scarcity in the supply of old crucibles, and bids fair to open a new market for burned graphite, says the *American Manufacturer*. Old crucibles, which could be had a year ago at 1 dol. per ton, cannot now be obtained in any quantity for 10 dols. per ton.

The present supply of graphite for use in making crucibles for steel-making comes from Ceylon. Elaborate experiments have been made with the plumbago mined in the United States, in the hope of making crucibles for this purpose therefrom, but so far with but indifferent success, or, at the most, with less success than with the imported article, nor has it been possible to sell the home product so cheaply.

Within the last year the price of plumbago delivered in New York has advanced nearly 60 per cent., due primarily to two causes—the quantity mined has fallen off, and the demand, especially outside the United States, has increased. The total amount of plumbago exported from Ceylon for the year ending June 1st, 1890, was 161,874 cwt. For the year ending June 1st, 1891, it was 148,043 cwt., a falling-off of over 8 per cent. At one time three-fourths of the entire production of the island came to the United States, but at present this country does not receive one-half, and the proportion that it does receive is on the decrease. In the year ending June 1st, 1890, 68,726 cwt. of Ceylon graphite came to America, and in the year ending June 1st, 1891, only 35,936 cwt.

Germany is becoming a large factor in the trade in the matter of consumption, its increased use by the Krupp works being responsible for this. The imports of Germany for the year ended June 1st, 1889, amounted to only 3,094 cwt. In 1890 it was 14,215 cwt. and in 1891 about 11,000. The falling off noted from 1890 to 1891 was about proportionate to that in the output, and not due to any lack of demand on the part of that country. During the fiscal years of 1890 and 1891 the imports of graphite in England amounted to 61,949 cwt. and 57,906 cwt. respectively.

The price of plumbago varies according to its quality. It is divided into four grades, viz., large lump, ordinary lump, chip, and dust. The present ruling figures are as follows: Lump (ordinary), 4.50 dols. to 5 dols. per cwt.; chip, 3.60 dols. to 4 dols.; dust, 2.80 dols. to 3.50 dols. There is a very great scarcity of good plumbago in the market to-day, and no cargoes of any consequence are expected in this country before 1st September.

The quality of plumbago depends as much upon its physical structure as upon its chemical analysis. There is a deposit of this mineral near Reading, Pa., which in analysis is practically identical with the best Ceylon article, yet the best efforts of crucible makers have failed to produce crucibles therefrom equal to those of the Ceylon graphite.

DISCOVERY OF COAL NEAR MIDDLESBROUGH.

The discovery of coal at Cowpen, near Middlesbrough, has been the topic of the past few days. What makes the find particularly interesting is the fact that it has been stated by scientists that there could not be coal beneath the salt-beds. The coal found at Cowpen, however, is beneath the salt. Some time ago salt was struck at Cowpen at a depth of between 700 and 800 feet, and the Newcastle Chemical Company, continuing to bore, struck a few weeks ago a fair quantity of natural gas. Still boring experimentally, they last week found a 2-foot seam of coal at a depth of nearly 2,000 feet. It is stated that the firm have reasons for believing that there is more coal beneath the present find.—*Ironmonger*.

THE NEW FLORIDA PHOSPHATE LAW.

A bill regulating the mining of phosphate rock in the beds of the navigable rivers of Florida was passed by the Legislature last month, on the last day of the session, and having been signed by the Governor, has become a law. By its provisions the Governor, Comptroller, and Attorney-General of the State are constituted a board of phosphate commissioners, which has the management of the phosphate interests of the State in the beds of the navigable streams. The right to mine these deposits is to be granted upon the following terms: for each ton of rock analysing less than 55 per cent. phosphate of lime, the State is to receive royalty of 50 cents; for rock analysing between 55 per cent. and 60 per cent. phosphate of lime, 75 cents; and over 60 per cent., 1 dol., accounts and payments to be rendered quarterly to the State Treasurer. The board is authorised to grant the exclusive right to mine rock from the beds of navigable streams, within certain well-defined limits, in no case exceeding 10 miles by course of stream, for a period not to exceed five years, preference being given to riparian owners and to those who have commenced or prepared to mine in good faith before the passage of the Act. Provision is made for the appointment of an inspector of phosphates as the executive officer of the board, and suitable penalties are imposed for non-compliance with the terms of the law.

As was to be expected, this law has elicited much opposition, and will undoubtedly lead to litigation between the State and many of the companies which claim vested rights in the river phosphate deposits. Very many of the mining companies are unaffected, however; the law not applying in cases of navigable streams or parts thereof that are not meandered and the ownership of the lands embracing which is vested in a legal purchaser.

It is not probable that the burden imposed by the new law will have serious effect upon the industry. The Florida river phosphate can be produced and loaded upon vessels at Gulf of Mexico ports as cheaply as South Carolina rock at Charleston. Under the present conditions, the former paying a royalty of 1 dollar per ton and the latter 2 dollars, the relative position of the two is the same as before the passage of the new laws in each of the States, the advantage still being strongly in favour of the Florida rock. Whatever may be the result of the new Florida law, the industry is likely to make great progress in that State during the present year. The trouble in South Carolina between the State and the Coosaw Mining Company is still unsettled, and river-mining industry there is practically at a standstill, Florida rock taking its place in the market to a considerable extent.

BOARD OF TRADE RETURNS.

Rosin..... Cwt.	149,047	200,503	37,977	54,758
Tallow and stearin ..	17,867	123,718	223,276	158,752
Tar..... Barrels	28,615	10,183	18,965	5,527
Wood:—				
Hewn..... Loads	262,942	220,726	585,900	479,042
Sawn..... ..	834,605	683,487	1,914,144	1,474,811
Staves..... ..	17,101	13,842	82,326	40,079
Mahogany..... Tons	2,967	1,973	25,063	17,515
Other articles.... Value £	810,777	856,302
Total value.....	4,492,390	3,967,914

Besides the above, drugs to the value of 74,894, were imported as against 58,068, in July 1890.

IMPORTS OF OILS FOR MONTH ENDING 31ST JULY.

Articles.	Quantities.		Values.	
	1890.	1891.	1890.	1891.
Cocoa-nut..... Cwt.	1,065	18,075	£ 1,534	£ 26,698
Olive Tuns	1,983	3,157	77,335	127,207
Palm Cwt.	90,123	91,729	101,000	101,908
Petroleum Gall.	10,925,318	9,117,850	209,089	197,196
Seed Tons	1,232	983	32,181	27,503
Train, &c..... Tuns	1,857	3,007	16,461	62,912
Turpentine Cwt.	61,224	76,727	91,390	105,911
Other articles .. Value £	66,562	76,513
Total value of oils	629,164	726,156

EXPORTS OF METALS (OTHER THAN MACHINERY) FOR MONTH ENDING 31ST JULY.

Articles.	Quantities.		Values.	
	1890.	1891.	1890.	1891.
Brass..... Cwt.	10,774	10,825	£ 50,302	£ 16,811

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

APPLICATIONS.

11,999. C. H. Roeckner, F. L. Roeckner, and R. L. Roeckner. Improved means and apparatus for clarifying and purifying liquids. July 15.

12,053. L. Damaze. Improvements in apparatus for measuring temperatures and pressures. July 15.

12,111. W. McLaren and P. Holmes. Improvements in or relating to the refrigerating medium employed in "freezing" and similar machines. Complete Specification. July 16.

12,124. R. Anderson. Improvements in liquor-raising apparatus. July 17.

12,174. C. Gautsch. Improved apparatus for use in the preparation of chemical solutions or liquids for the extinguishing of fire. July 17.

12,389. H. C. Sergeant. Improvements in compound compressors for air and other gaseous or aeriform bodies. Complete Specification. July 21.

12,391. M. Hengmann. Improved apparatus for heating gases. July 21.

12,401. L. Gye. Improvements in means or apparatus for drying or extracting moisture. July 21.

12,469. E. Hesketh and A. Marec. Improvements in machinery or apparatus for producing cold by the employment of carbonic anhydride. July 22.

12,516. C. Ferguson. Improvements relating to the revivification of charcoal. July 23.

12,542. E. Donard and G. Boulet, jun. Improvements in evaporators. Complete Specification. July 23.

12,576. E. Hesketh and A. Marec. Improvements in machinery or apparatus for producing cold by the employment of carbonic anhydride. July 25.

12,700. J. A. Mays. Improvements in the separation and concentration of solids. July 27.

12,796. B. Rettenmeyer. Improvements in cooling apparatus for liquids. Complete Specification. July 28.

12,815. R. P. Barnstead, R. H. Spalding, and J. C. Billard. Improvements in water-distilling apparatus. Complete Specification. July 28.

12,858. W. Ackroyd and W. Emmott. Improvements in refrigerating apparatus. July 29.

12,998. G. Rodger. Improvements in or connected with means of apparatus for heating metals by liquid or gaseous fuel. July 31.

13,069. C. Ferguson. See Class XVI.

13,086. T. O. Harrison and W. Watson. The manufacture of a preparation or composition for preventing or lessening corrosion or incrustation in steam boilers. August 1.

13,222. E. Freund. Improvements in filtering apparatus. August 5.

13,323. J. H. Minto. Improvements in apparatus for charging liquids with gases. August 6.

13,447. A. Colson. Improvements in column stills for distillation of gas liquor and other liquids. Complete Specification. August 8.

13,522. J. Reed. Improvements in or connected with condensers. August 11.

13,523. J. Reed. Improvements in or connected with evaporators, in part applicable to feed-heaters and condensers or distillers. August 11.

13,612. R. Krom. See Class XVII.

COMPLETE SPECIFICATIONS ACCEPTED.*

1890.

10,374. J. Gangee. Process and apparatus for condensing or liquefying vapours or gases. August 12.

13,284. J. Foster. Evaporating apparatus. August 12.

14,380. L. Johnstone. See Class IX.

15,698. R. A. Robertson, Jot Mirreles, Watson, and The Varyan Co., (Lm.) and D. Ballingall. Apparatus for evaporating, concentrating, and distilling liquids. August 12.

15,930. C. Kellner. See Class XIX.

15,931. C. Kellner. See Class XIX.

17,218. J. Zeller. Process for obtaining a new material from bituminous slate, and its application as a filtering medium, and as a colouring matter. August 19.

* See Note * on previous page.

1891.

7867. W. P. Thompson. — From Wirth and Co. Evaporating apparatus for concentrating liquids. July 29.

7869. W. P. Thompson. — From Wirth and Co. Evaporating apparatus for concentrating liquids of a pulpy nature. July 29.

8551. J. H. Day. Process and apparatus for moulding plastic or viscous substances into the form of thin bauds or ribbons. July 29.

9351. J. Zubr. Retort furnaces. July 29.

11,043. G. W. Miller. Faucets for measuring fluids. August 5.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

11,885. J. Bartlett. Fuel block and fire-lighter combined. July 13.

12,256. J. Stevenson. Improvements relating to a method of transporting and delivering purifying material used in the manufacture of gas, and to apparatus therefor, such apparatus being applicable also for other purposes. July 18.

12,396. H. H. Leigh. — From T. Bauer and G. Mendheim, Germany. Improvements in coke ovens. July 21.

12,572. G. E. Stevenson. Improvements in apparatus for charging inclined gas retorts. July 24.

12,818. A. Hickenlooper. Improvements in gas retort chargers. Complete Specification. July 28.

13,036. G. Weld, jun., and G. H. Rayner. Improvements in the manufacture of oxygen gas. July 31.

13,089. P. Dykowitz, The Kerosene Co., Lim., and The Tank Storage and Carriage Co., Lim. A new or improved method of and apparatus for distilling liquid hydrocarbons. August 1.

13,153. R. Barton. An artificial fuel compound. August 4.

13,179. D. C. Fischel. Improvements in artificial fuel. Complete Specification. Filed August 4. Date applied for January 5, 1891, being date of application in United States.

13,404. C. C. Black and S. Alford. An improved method for utilising the non-combustible portion of coal and other inflammable material, and furnace refuse generally. August 8.

13,431. J. H. Fergusson. Improvements in or connected with the manufacture of illuminating gas. August 8.

13,506. P. Dykowitz. Improvements in the manufacture of illuminating gas. Complete Specification. August 10.

13,550. W. L. Wise. — From Solvay and Co., Belgium. Improvements in the purification of gas. August 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

13,332. H. Stevenson. Method and apparatus for heating. July 29.

14,109. J. A. Rossiter. Means for generating heat. August 12.

14,112. S. A. Johnson. Effecting combustion of fuel, and prevention of smoke in steam boilers. August 5.

14,618. W. B. Lampard. Apparatus for charging inclined gas retorts. July 22.

16,207. F. Siemens. Means of utilising waste gases in regenerative gas furnaces. August 12.

1891.

9474. E. Luhnmann. Extraction of gases from fluids. August 5.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

12,441. A. Ashworth. Improvements in the production of colouring matters. July 22.

12,557. R. Hirsch. Improvements in the manufacture of aniline. July 24.

12,589. H. H. Lake.—From Kalle and Co., Germany. Improvements in the manufacture of colouring matters. July 24.

13,677. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co., Germany. Improvements in the manufacture and production of colouring matters derived from anthraquinone and alizarin blue. August 13.

13,693. A. Lembach, F. Schleicher, and C. J. Wolff. A new soluble quinoline derivative. Complete Specification. August 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

14,621. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co. Production of rosaniline derivatives or leuco bodies of the tri- or di-phenyl-naphthyl-methane series, and colouring matters therefrom. July 22.

14,836. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. Production of a sulpho acid suitable for dyeing and printing. July 22.

15,345. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co. Production of blue colouring matters. July 22.

15,346. S. Pitt.—From L. Cassella and Co. Manufacture of azo-dyestuffs, and of materials for their production. August 5.

15,347. S. Pitt.—From L. Cassella and Co. Production of azo-colours in substance or on the fibre. August 12.

15,778. M. Lange. Separating orthotoluol-sulphonic and paratoluol-sulphonic acids. July 29.

15,803. J. Y. Johnson.—From the Badische Anilin und Soda Fabrik. Production of a new naphthalene derivative for manufacture of dyestuffs. August 5.

16,666. J. R. Geigy. Production of a yellow colouring matter or dye. July 29.

16,868. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. Manufacture and production of a new blue basic dyestuff. August 5.

17,168. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. Manufacture of sulpho-acids of a red basic naphthalene colouring matter. August 19.

17,218. J. Zeller. See Class I.

19,167. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik. Manufacture of sulpho-acids of a red basic naphthalene dyestuff. July 22.

1891.

9636. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co. Production of black azo-colours upon fibres. August 19.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

11,937. W. H. Bailey. Improvements in the method of and apparatus for washing and cleansing wool and other fibres. July 14.

12,679. F. V. M. Raabe. Improvements in the manufacture of yarns from certain vegetable waste fibres. July 25.

12,681. W. E. Gedge.—From F. Mommer and Co., Germany. An improved process and apparatus for treating textile fibres in bobbins with a liquor. July 25.

12,708. W. Ellis and S. E. Stirzaker. Improvements in the treatment of wool for removing vegetable matter, burrs, and the like therefrom. July 27.

12,817. A. J. Boulton.—From B. Beyer, Germany. A process of treatment of waste raw silk or "burr" with a view to its employment for manufacture of underclothing or the like. Complete Specification. July 28.

13,072. J. P. A. Blaye. Improved process and means for the chemical treatment of ramie fibre, flax, or hemp, in either a green or dried state. August 1.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

13,965. K. T. Sutherland and G. Esdaile. Treatment of long-staple stalk-fibres, such as China-grass, flax, to give them a more even staple when artificially shortened. July 22.

1891.

7458. S. C. Dhondy. Sizing compounds for cotton yarn. August 5.

11,717. A. Frayssé. Treatment of samples of crude wool for estimating purposes. August 19.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

11,847. J. Frost and E. Cuno-Kayser. Improvements in the production of dyes on textile fibres and other like materials. July 13.

11,936. F. Hurter. Improvements in bleaching wood, cane, or other fibrous materials, and the preparation of an agent to be employed therein. July 14.

11,943. W. P. Thompson.—From G. Raeithel and J. Rosenthal, Germany. Improvements in the apparatus for clarifying, by means of filtration, dye-vats. July 14.

12,471. R. J. Loeffler and E. Kur. A method and apparatus employed in dyeing, drying, and otherwise treating textile materials. July 22.

13,102. G. A. Cannot. Improvements in the process of and apparatus for bleaching and treating the fibre of peat, or other fibrous substances. August 1.

13,509. C. F. Pike. Improvements in the method of and in apparatus for bleaching and treating textile fabrics. August 11.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

11,965. P. de Wilde. Method of utilising the "Weldon" plant for the manufacture of precipitated phosphates. Complete Specification. July 14.

12,317. F. M. Lyte and C. H. M. Lyte. Improvements in the production of chlorine and certain by-products. July 20.

12,522. E. Brochon. An improved process and apparatus for enriching or concentrating phosphates of lime. July 23.

12,538. F. M. Lyte. See Class X.

12,621. R. W. Forrest and W. Forrest. Improvements in obtaining cyanides or cyanogen compounds. July 25.

12,763. W. Donald. Improvements in treating chlorides to obtain chlorine, hydrates, and other salts or chemical compounds. July 28.

13,334. A. L. H. Knoop. Improvements relating to the extraction of carbonic acid from minerals, and to apparatus therefor. Complete Specification. August 6.

13,409. W. H. Higgin. See Class XIX.

13,424. G. I. J. Wells. Improvements in apparatus for the extraction of ammonia, applicable for ammonia-soda works and the like. August 8.

13,684. C. R. C. Tichborne, A. E. Darley, S. Geoghegan, and M. F. Purcell. An improved process and apparatus for the manufacture of solid carbonic acid (CO_2). August 13.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

14,483. T. Raymond. Production of soda and chlorine. July 22.

15,394. E. Richters. Utilising the silicic fluoride obtained by the treatment of certain phosphates with sulphuric acid. August 12.

15,460. D. Gamble.—From A. R. Peebney. Manufacture of chlorate of soda. August 19.

1891.

9646. F. Lohmann. Process for production of carbonic acid. August 5.

10,158. E. Lohmann. Production of carbonic acid from bicarbonate of soda. August 5.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

11,858. W. Walker. Improvements in glass furnaces. July 13.

12,016. C. Hueckel.—From O. Balthasar, Germany. Process for producing china flowers serving as lamp shades or globes. July 15.

12,852. F. T. Poyer. Improvements in or relating to ovens or kilns for the firing of bricks, tiles, potters' goods and the like, by gas. July 29.

13,354. H. Lane and A. Chamberlain. Improvements in annealing furnaces. August 7.

13,567. F. Urban. Improvements in the manufacture of glass hollow ware. August 11.

13,738. W. Schlemming. Improved process of producing imitation terra cotta. August 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

14,771. J. L. de Jongh. Glass tiles suitable for roofs in conjunction with sheets of corrugated iron. July 22.

16,453. D. Rylands. Manufacturing glass conduits or tubes for electrical or other purposes. August 19.

16,422. C. K. Mills.—From J. B. Granjon and F. Allemand. Moulding and firing hollow articles. August 19.

1891.

8090. G. Gehring. Enamel for metals, glassware, earthenware, and other materials. August 19.

10,218. O. Boklen. Manufacture of slabs or tiles. August 19.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

12,219. W. J. Reagan and R. R. Longley. An improved composition of matter for plastering walls, &c. Complete Specification. Filed July 18. Date applied for January 20, 1891, being date of application in United States.

12,429. F. J. Reynolds and J. Brown. Producing an improvement in building cements. July 22.

12,633. T. D. Harries. An artificial stone. July 25.

12,664. C. Smith.—From J. G. Maardt, Denmark. Improvements in white decorative stucco or parqueting. July 25.

12,730. F. Wachsmath. Process for use in the manufacture of gypsum objects. July 27.

12,806. J. Maclear and D. A. Sutherland. Improvements in the treatment of stone for hardening the same. July 28.

13,016. G. Williams. Improved process of manufacturing hydraulic cement. July 31.

13,035. C. Roswag. Improvements in and relating to the preparation of refractory materials. July 31.

13,255. C. Scheurenberg. Process for the manufacture of artificial stones. August 5.

13,491. C. H. Köpke. An improved fireproof material. Complete Specification. August 10.

13,616. C. Bloemendal. An improved process and apparatus for producing hydraulic mortar. August 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

10,962. R. G. de Vasson and The Société dite La Suberine. Manufacture of plastic compounds for building and other purposes, and apparatus therefor. July 22.

12,607. C. George. Manufacture of artificial stone. July 29.

13,595. H. P. Williams and E. G. Williams. Improved artificial asphalt. August 19.

11,380. L. Johnstone. Rotative furnaces or kilns for treating and recovering waste gases from raw or partially raw materials, applicable especially in the manufacture of cement. August 5.

1891.

9189. W. Corbould. Manufactured whiting. July 29.

10,080. A. Schöfer. Apparatus for drying cement, clay, and other materials for burning or calcining. July 23.

11,259. E. E. A. Sorel. Materials for the manufacture of bricks and other articles, the building of fortifications and the protection of vessels. August 12.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

12,146. H. H. Lake.—From J. C. Pennie, United States. Improvements in apparatus for disintegrating ores and other substances, and particularly for separating metals and metallic compounds from their gangue. July 16.

12,156. N. Lébédoff. Improvements in smelting iron, nickel, and copper. July 17.

12,165. J. Wilmotte. An improved converter for the manufacture of iron and steel. Complete Specification. July 17.

12,292. I. Willey and C. D. Bartle. Improvements in slime separators for use in the treatment of tin and other ores. July 20.

12,298. W. S. Simpson. Improved means and apparatus for facilitating the casting of metal articles in vacuo. July 20.

12,405. J. W. Richards. Improvements in the manufacture of galvanised iron. Complete Specification. July 20.

12,538. F. M. Lyte. An improved process for the production of lead, conjointly with the production of chlorine, and of certain sulphates as by-products. July 23.

12,675. N. Lebedeff. Improvements in the reduction of metals from their combinations with oxygen. July 25.

12,813. A. Crossley. Improvements in apparatus for producing ferro-ferrie and ferrie oxides. July 28.

12,841. L. Cameron. Improvements in the manufacture of steel. July 29.

12,917. F. W. Harbord and W. Hutchinson, jun. Improvements in utilisation of tin plate scrap. July 30.

13,029. C. Roswag. Improvements in and relating to the extraction of copper and other substances from ores and the like, and to the treatment of the products obtained therefrom. July 31.

13,068. B. Rösing. Improvements in treating lead for purifying it, and for obtaining litharge, or for separating the lead from the precious metals contained in it. August 1.

13,354. H. Lane and A. Chamberlain. Improvements in annealing furnaces. August 7.

13,395. E. Meyer. Improvements relating to the extraction of aluminium hydrate or aluminium salts from aluminium silicates or clay. August 7.

13,670. The London Metallurgical Co., Lim., and S. O. Cowper-Coles. Improvements in coating or plating metals and metallic articles, applicable also for the manufacture of bullets. August 13.

13,711. M. Mannaberg and J. Cliff. Improvements in the manufacture of steel. August 14.

13,713. M. Mannaberg and J. Cliff. Improvements in the construction of steel smelting furnaces. August 14.

13,739. C. James. An improved method of treating leady copper "mattes" and ores. Complete Specification. August 14.

13,740. C. James. An improved method of smelting complex silver ores. Complete Specification. August 14.

13,796. H. Pidot. Iron silver. August 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

10,940. H. A. von Vught. Preparation for hardening iron all through. July 22.

11,877. H. H. Lake.—From La Société Vanzetti Sagramoso and Co. Manufacture of steel. July 29.

14,768. F. W. Martino and F. R. Martino. Metallic alloys. July 22.

15,174. C. L. C. Berton. Recovery of tin and iron from waste pieces or clippings. July 29.

15,475. G. A. Decosse and V. Lespinats. Process for making all kinds of rolled iron. July 22.

16,344. R. S. Casson. Manufacture of steel and ingot iron. August 19.

1891.

4793. W. B. Middleton. Treatment of steel. July 29.

8881. F. J. Page and H. A. Anderson. Soldering aluminium. July 22.

9341. J. H. Rogers. Apparatus used in the manufacture of tin andterne plates. August 19.

11,083. J. Bowing. Method of treating blue billy or purple iron ore, iron, sand, and similar substances, for the purpose of preparing them for the reducing furnace. August 19.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

12,036. S. W. Maquay. Improvements in primary batteries. July 15.

12,069. H. D. Fitzpatrick.—From K. F. Scholler and R. H. Jahr, Germany. An improved electrode plate for electric collectors. Complete Specification. July 16.

12,296. A. S. Elmore. Improvements in apparatus for the manufacture by electrolysis of tubes and other articles of circular section. July 20.

12,313. E. C. C. Jungnickel. Improvements in electric batteries. July 20.

12,322. A. J. Boulton.—From J. H. Bassler, United States. Improvements in or relating to electrical welding. Complete Specification. July 21.

12,491. C. L. Baker and Woodhouse and Rawson United, Lim. Improvements in the construction of rheostats or similar electrical instruments. July 23.

12,592. H. H. Lake.—From Lacombe and Co., France. Improvements relating to the manufacture or preparation of carbons for electric lamps or lighting apparatus. July 24.

12,611. J. W. Swan. Improvements in or connected with the electrolytic deposition of copper. July 24.

12,898. T. Parker. Improvements in means to be employed in the electrical deposition of copper. July 29.

12,946. I. A. Timmis and W. H. Walenn. Improvements in the electro-deposition of platinum. July 30.

13,208. E. Casper.—From E. Viarengo, Italy. Improvements in the manufacture of wire, bars, bands, and sheets of copper by electrolysis, and in apparatus therefor. August 1.

13,146. W. J. S. Barber-Starkey. An improvement in secondary voltaic batteries. August 8.

13,160. The London Metallurgical Co., Lim., and S. O. Cowper-Coles. Improvements relating to the coating of articles with a new metallic alloy by electro-deposition. August 8.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

11,065. G. A. Oncken. Impregnation of organic fibrous and cellular matter by means of an electric current, and apparatus therefor. July 22.

11,601. A. H. Cowles.—From F. W. Matthiessen. Obtaining metals in molten condition from their fused oxides by electrical action. August 12.

14,411. J. T. Niblett. Secondary batteries. July 22.

14,624. A. S. Elmore. Manufacture of metallic articles by electrolysis, and apparatus for that purpose. August 19.

14,693. J. P. Bayly.—From J. Silico. Galvanic battery. August 5.

16,054. H. G. C. Serrin. Electric batteries. August 19.

16,279. N. Slawianoff. Process and apparatus for electrical casting of metals. July 22.

16,280. N. Slawianoff. Means of preventing blow-holes and other defects in castings by electricity. July 22.

16,399. A. J. Boulton.—From L. A. J. Joray. Electro-deposition of metals. August 19.

20,712. E. Ortell. Improvements relating to electric batteries. July 29.

1891.

8941. A. J. Boulton.—From E. E. Ries. Method and apparatus for electrical hardening and tempering. July 29.

9762. S. C. C. Currie. Secondary or storage batteries. July 29.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

11,889. O. C. Hagemann.—From E. K. Mitting, United States. Improvements in the treatment and purification of soapmakers' spent lye for extracting glycerin therefrom. July 13.

12,168. S. I. Browne and C. S. Browne. Improvements in the manufacture of soap. July 17.

13,186. H. Pfetznor. Improvements in apparatus for smelting tallow. August 4.

13,799. H. Monie and S. M. Butnagar. Improved detergents. August 15.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

10,753. A. E. St. George. Treatment of linseed and other oils employed in varnishes. August 19.

15,104. W. Majert. Manufacture of spermine. July 29.

1891.

9991. A. Siebels. Manufacture of iodine soaps. July 22.

10,132. C. Fink. Lubricants for machinery. July 22.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

12,480. J. C. Martin. Improvements in the manufacture of pigments or paints. July 23.

12,895. A. Gutensohn. An improved method and appliances for the production of litharge from metallic lead. July 29.

13,041. T. H. Rees and W. P. Blackham. Improvements in the manufacture of blue or other colouring or bleaching materials for washing purposes. August 1.

13,100. J. Hallett. An improved furniture polish. August 1.

13,429. J. Knowles. Improvements in or relating to laundry blue. August 8.

13,513. M. E. Dejonge. Improvements in anti-fouling and anti-corrosive compounds for ships' bottoms and other purposes. Complete Specification. August 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

12,123. G. Macaulay Cruikshank.—From E. Pietzcker. Preparation of rapidly-drying resinous and other oils or varnishes. August 5.

12,230. T. Christy. Substitute for gutta-percha, rubber, oiled and other transparent tissues. August 12.

15,564. J. P. Bayley.—From J. Bauleh. Improved blacking for leather. August 5.

1891.

4334. W. Grunshaw. Preparation of pigments or colouring compounds. August 19.

8510. H. Pennington. Process of manufacturing lead sulphate from metallic lead. July 29.

9747. H. Beck.—From F. Schaal. Manufacture of hard neutral resins as substitutes for natural resins, such as copal, amber, and the like. July 29.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

12,331. J. Shepherd.—From A. Krizek and R. Esché, Switzerland. Mineral size. July 21.

13,308. W. Francis, J. A. Carrick, B. Hooper, A. F. Grant, and H. A. Leverett. An improved process of rapid tanning. August 6.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

13,796. W. J. J. Hawkins. Printers' roller composition. August 5.

14,913. H. Belcher. Treatment of skins and hides for the preparation of leather. July 29.

1891.

7734. A. A. Hunting. Apparatus for treating or preparing leather. August 5.

XV.—AGRICULTURE AND MANURES.

APPLICATION.

12,522. E. Brochon. See Class VII.

COMPLETE SPECIFICATION ACCEPTED.

1890.

14,321. A. Buchanan.—From A. W. Tait. Compounds for protecting vines, potatoes, and other vegetable growths from disease. July 29.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATIONS.

11,874. R. Harvey. Improvements in and relating to the manufacture of sugar, and in apparatus therefor or connected therewith. July 13.

11,963. A. R. Bernhard and W. E. Youle. Improvements in the manufacture of gum, similar to gum arabic, and serving as a substitute therefor. July 14.

12,054. H. Klein and G. Dethan. Improvements in apparatus for automatically manufacturing cold syrups of a determined density. Complete Specification. July 15.

12,058. R. F. Cordero. Improvements in apparatus for decanting and evaporating saccharine juices. Complete Specification. July 15.

12,355. O. Mengelbier. An improved apparatus for sucking off the green syrup from sugar masses, and purifying the latter. July 21.

12,518. C. Ferguson. Improvements in the manufacture or refining of sugar. July 23.

12,520. C. Ferguson. Improvements in the manufacture or refining of sugar. July 23.

12,808. R. F. Cordero. Improvements in apparatus for washing sugar. Complete Specification. July 28.

13,069. C. Ferguson. Improvements in or relating to the dissolving of sugar and other substances. August 1.

13,260. T. Drost. Improvements in the process and means for manufacturing crystallised sugar in refineries. August 5.

13,278. J. Cavargna. Improvements in concentrated and solidified gums for cementing paper, leather, fabrics, and other articles. August 6.

COMPLETE SPECIFICATION ACCEPTED.

1891.

12,054. H. Klein and G. Dethan. Apparatus for automatically manufacturing cold syrups of a determined density. August 19.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

12,501. J. Walker and H. Higgott. An improved method or composition for cleansing foul casks and other vessels. July 23.

12,506. C. Rach. Process for the preparation of wort from malt or unmalted cereals. Complete Specification. July 23.

12,606. A. Walker. An improved mode of manufacturing yeast. July 24.

12,641. E. Dugdale. Improvements in beverages and their manufacture. July 25.

12,659. V. Denamur. Improvements in apparatus for the manufacture or brewing of beer. July 25.

12,668. H. Elion. Improvement in the purification of yeast. July 25.

13,047. W. Dawson. Improvements in or relating to distillers' safes, said improvements being also applicable for check sampling the spent wash at outlets of "Patent" stills, and for taking and testing samples of liquids generally at different times or stages of manufacture. Complete Specification. August 1.

13,088. H. E. Newton.—From La Société Anonyme "La Levure," France. Improvements relating to the production and preservation of pure yeast. August 1.

13,353. A. Boake, F. G. A. Roberts, and W. B. Giles. Improvements in the preparation and treatment of worts for brewing and distilling purposes, and in the cultivation of yeast. August 7.

13,684. C. R. C. Tichborne, A. E. Darley, S. Geoghegan, and M. F. Purcell. See Class VII.

13,729. O. Perrier. Improvements in distilling and rectifying alcohol or other liquids, and in apparatus employed therein. August 14.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

17,640. R. H. Leaker and J. H. Howell. Improvements relating to brewers' and distillers' fermenting vessels and yeast receivers. August 5.

1891.

11,183. F. Bollmann. Malting apparatus. August 5.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

12,191. E. Barker. Improvements in or relating to the preparation or treatment of certain waste products to make them suitable for use as food, and in apparatus therefor. July 17.

12,549. J. H. H. Duncan. Improvements in the manufacture or production of butter. July 24.

12,838. A. Goldthorp. An improved process for purifying and clarifying water containing calcareous and metallic inorganic and organic substance or matter. July 29.

13,212. D. Tallerman. Improvements in the preparation of cattle foods. August 5.

13,369. G. C. Dymond.—From T. B. Taylor, United States. New or improved cereal food, and method of manufacturing the same. Complete Specification. August 7.

13,392. G. W. Richards. Improvements in the manufacture or production of articles of food for human consumption. August 7.

13,615. H. Carns-Wilson. An improved process for the treatment of tea. August 12.

B.—Sanitary Chemistry.

12,025. W. H. Munns.—From A. F. Black, United States. Improvements in apparatus for treating sewage. July 15.

12,466. E. E. Scraby. An improved process for treating sewage sludge and the like. July 22.

12,567. S. Phillips and S. F. Smart. Phillips and Smart's disinfecting and ozonising air filter. July 24.

12,947. S. A. Johnson. Improvements in means for purifying smoke and collecting and condensing the products contained therein. July 30.

13,326. W. Wade. Improvements in or connected with means for purifying or filtering sewage. August 6.

13,757. A. Mylins. Method of purifying liquids, more particularly sewage and waste water, and apparatus appertaining thereto. Complete Specification. August 11.

13,758. A. Mylins. Method of sterilising liquids, particularly sewage, and apparatus appertaining thereto. Complete Specification. August 14.

C.—Disinfectants.

11,978. A. R. Upward. A system and apparatus for the evolution and diffusion, by electrical energy, of disinfectants, antiseptics, and substances of a like nature. July 15.

12,033. A. J. Eli.—From F. Chavanon, France. A new or improved disinfectant. July 15.

12,247. E. Soy. A new method of using sulphurous acid gas as a disinfectant, and for other medical purposes. July 18.

13,139. T. McMurray. New or improved compounds to be used for disinfecting, deodorising, germicide, sanitary, manuring, and like purposes. August 4.

13,262. H. B. Thornton. Improvements in or appertaining to disinfectants for water-closets and other places or things where water is used. August 5.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1891.

5196. C. B. Lesser. Process for the preparation of condensed milk. August 19.

B.—Sanitary Chemistry

1890.

14,253. A. O. Jones and S. Fox. Treatment of sewage. August 19.

14,858. R. Leigh. See Class XVIII.—C.

C.—Disinfectants.

1890.

14,858. R. Leigh. Deodorising, disinfecting, and oxidising substances. August 5.

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATIONS.

12,970. C. Kellner. Improvements in the boiling process for producing cellulose by means of sulphurous acid. Complete Specification. July 31.

12,971. C. Kellner. An improved process and apparatus for preparing the wood in the manufacture of wood fibre. Complete Specification. July 31.

13,225. F. B. Stanley. Improvements in the manufacture of coloured and figured goods of celluloid and like material. August 5.

13,400. W. H. Higgin. Improvements in the treatment and utilisation of esparto liquor and other similar waste liquors and by products. August 8.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

15,697. A. W. Hayles. Manufacture of paper and paper pulp from home and foreign grown marsh reeds, Danube reeds in particular. August 12.

15,930. C. Kellner. Lining boilers and digesters used in the manufacture of paper pulp and for other similar purposes. August 12.

15,931. C. Kellner. Lining boilers or digesters used in the manufacture of paper pulp and for other similar purposes. August 12.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

11,957. W. Majert. Improvements in the manufacture of piperazine or spermine. July 14.

12,729. B. Hascholl. Process for the production of a palatable kola nut powder. July 27.

13,613. A. Baur. Improvements in the manufacture of artificial musk. August 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

16,392. B. J. B. Mills. From G. P. Monnier and Carlier. Receiver for the preservation and application of chloride of ethyle. July 22.

17,547. G. de Lamo. Manufacture of iso eugenol and of certain of its derivatives and their application to the manufacture of vanilline. August 19.

XXI.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

12,303. E. W. Anderson. Improvements in machinery for the manufacture of cordite and like explosives. July 20.

12,171. J. Heath and W. Frost. A safety fuse lighter. July 22.

13,038. H. de Moseuthal, A. G. Salamon, and J. J. Hood. Improvements in explosives. July 31.

13,218. J. Heilmann and P. T. Riddett. Improvements in or connected with fuses for mining or other purposes. August 5.

13,507. W. H. A. Kitchen and J. G. A. Kitchen. A new manufacture of explosive. August 10.

13,612. R. Kron. A centrifugal machine for separating acid from nitro-cellulose, or for other like purposes. Complete Specification. August 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

15,483. H. H. Lake. From H. S. Maxim. Manufacture of explosives and apparatus therefor. August 5.

16,002. J. S. Taylor and S. W. Challen. Processes for producing gunpowder cake. August 12.

16,189. H. H. Lake. From E. T. G. Thorn, G. R. O. Westendorp, and G. L. C. Pieper. Manufacture of explosives. August 12.

1891.

11,383. C. H. Curtis and G. André. Manufacture of gunpowder. August 12.

XXII.—ANALYTICAL CHEMISTRY.

COMPLETE SPECIFICATIONS ACCEPTED.

1891.

10,492. J. Laidlaw. Centrifugal apparatus for testing relative volumes of mixtures of liquids of different specific gravities. August 19.

11,717. A. Frayssé. Treatment of samples of crude wool for estimating purposes. August 19.

PATENT UNCLASSIFIABLE.

APPLICATION.

13,573. E. Hughes. From E. V. C. Bichon, France. A new or improved chemical compound. August 11.

THE JOURNAL OF THE Society of Chemical Industry: A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 9.—VOL. X.]

SEPTEMBER 30, 1891.

[Non-Members 30/- per annum; Members
21/- per Set of extra or back numbers;
Single Copies (Members only) 2/6.]

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond, F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook.	1890—1891.

COUNCIL FOR YEAR ENDING JULY, 1892.

President: Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.

Vice-Presidents:

Sir Lowthian Bell, Bart., F.R.S.	Ludwig Mond, F.R.S.
Wm. Crowder.	Dr. Hugo Müller, F.R.S.
James Duncan.	B. E. R. Newlands.
Dr. John Evans, F.R.S.	J. C. Stevenson, M.P.
David Howard.	A. Norman Tate.
S. H. Johnson.	Sir John Turney.

Ordinary Members of Council:

A. H. Allen.	E. K. Muspratt.
Arthur Bonke.	T. L. Patterson.
Jno. Calderwood.	Boverton Redwood.
Dr. Charles Dreyfus.	Jno. Spiller.
H. Grimshaw.	T. W. Stuart.
Prof. R. Meldola, F.R.S.	William Thorp, B.Sc.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Dr. F. Hurter.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

THE JOURNAL.

Publication Committee:

The President.

A. H. Allen.	Prof. A. K. Huntington.
L. Archbutt.	F. Hurter, Ph.D.
G. H. Bailey, D.Sc., Ph.D.	Wm. Kellner, Ph.D.
Joseph Bernays, M.I.C.E.	Ludwig Mond, F.R.S.
H. Brunner.	T. W. B. Mumford.
E. Rider Cook.	B. E. R. Newlands.
W. Y. Dent.	John Pattinson.
Chas. Dreyfus, Ph.D.	W. H. Perkin, Ph.D., F.R.S.
John Heron.	Boverton Redwood.
D. B. Hewitt, M.D.	John Spiller.
David Howard.	A. Norman Tate.
Prof. J. J. Hummel.	Wm. Thorp.
	Thomas Tyrer.

Editor:

Watson Smith, University College, London, W.C.

Assisted by the following Staff of Abstractors:

S. B. Asher Aron. IV., IX., X.	T. A. Lawson, Ph.D.

NOTICES.

Prints of the group photographed at Trinity College, Dublin, may be had on application to W. Lawrence, Photographer, 5—7, Upper Sackville Street, Dublin, price 5s. each.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 44 of the bye-laws, the Society has the right of priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SPOTTISWOODE, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January and May 1883, and January, February, and April 1886. Members possessing odd copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

CHANGES OF ADDRESS.

Anderson, W. F., 10 20; 11, Montague Road, Dalston, N.
Campbell, Archibald, 10 Clydebank; Thornton, R.S.O.,
Ile, N.B.

Collins, C. S. A., 1/0 Albert Place; 56, Elm Row, Leith
Walk, Edinburgh.

Corbould, W. H., 10 Broken Hill; Ediacara Consols
Silver Mine, Beltana, South Australia.

Davis, George E., 10 South Cliff House; Kersal House,
Higher Broughton, Manchester.

Fogg, James, 10 Glasgow; Waterloo Estate, Carap-
banna, Trinidad.

Francis, Wm., jun., 10 Glasgow; 7, Shaftesbury Square,
Belfast.

Greenway, T. J., 10 Port Pirie; 8th Avenue, East
Adelaide, South Australia.

Hetherington, Dr. A. E., 10 High Street; 65, Sandown
Lane, Weybridge, Liverpool.

Holloway, G. T., 10 Battersea; 57 and 58, Chancery
Lane, London, W.C.

Jackson, G. B., 10 Coughton; Norbriggs, Lytham,
Lancashire.

King, C. M., 10 Portugal; 24, Goddman Street, London,
E.C.

Lewis, A. L., 10 Dublin; 94, Tritonville Road, Sandy-
mount, Dublin.

MacKenzie, Dr. W. Cossar, 10 Edinburgh; Durham
College of Science, Newcastle-on-Tyne.

Mann, Jno. C., 10 Barking Road, 19, New City Road,
Plumstead, E.

Mordle, F. Dare, 10 Highbury Vale; Fishpond Drive,
The Park, Nottingham.

Ree, Dr. A., 10 Fallowfield; 6, Brighton Grove,
Rusholme, Manchester.

Sanderson, T. C., 10 Highbury; 157, Brooke Road,
Clapton, E.

Sandford, P. Gerald, 10 Hayle; Blandford Lodge,
Streatham, S.W.

Shaw, H. D., 10 Sandaly; Bond Street, Dewsbury, Yorks.

Snail, J. L., 10 Iquique; c/o Ant. Gibbs and Sons, 15,
Bishopsgate Street Within, E.C.

Smith, Dr. J. H., 10 Hottingen; Wollishofen, Zurich,
Switzerland.

Stuart, T. W., 10 Hepburn; 15, Windsor Terrace,
Newcastle-on-Tyne.

Wates, E. A., 10 Secunderabad; Lingsugur, Deccan, India.

Williams, D., Journals to c/o United Alkali Co., Ltd.,
Kurtz Branch, St. Helens.

Wilson, Jno., 10 Gateshead; 28, Crosby Road, Romford
Road, Stratford, E.

Woolf, Mortimer, 10 West Hampstead; 16, Greville
Place, London, N.W.

Wylde, J. R., 10 Penketh; Fazakerley House, Preseot,
Lancashire.

CHANGE OF ADDRESS REQUIRED.

Wm. Zinkeisen, 1/0 508, New City Road, Glasgow.

Deaths.

Hardy, H. J., 163, Edmund Road, Sheffield.

Staveley, W. W., Baghill, Pontefract.

London Section.

CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

Chairman: T. Tyrer.

SESSION 1890-91.

Probable Arrangements.

1891:—

Nov. 2nd (Monday):—

Mr. W. C. Young. "On Volatile Organic Matter in Potable
Water and a simple Method of Estimating Volatile and
Non-Volatile Matter in Water."

Dr. S. Ruben. "Some Experiments on Solidifying Petroleum."

Dec. 7th:

Mr. Watson Smith. "A Contribution to our Knowledge of
the Soluble and Resinous Constituents of Bituminous
Coals."

Dr. Murray Thompson. "The Salt Industry of India."

1892:—

Jan. 4th: Mr. Boverton Redwood. "The Gallician Petroleum
Industry."

Journal and Patent* Literature.

I.—GENERAL PLANT, APPARATUS, AND MACHINERY.

PATENTS.

Improvements in Apparatus for Evaporating Liquors containing Salts, and for Separating such Salts when rendered Insoluble by Evaporation of the Liquors. E. G. Lawrance, London. From S. Pick, Szezakowa, Austria. Eng. Pat. 4532, March 22, 1890. 8d.

THE improvement consists in an easily removable heating chamber of known construction, as applied to the inventor's well-known evaporator (this Journal, 1891, 624). The heating chamber contains a series of small tubes, arranged round a tube of relatively larger diameter; the tubes contain the liquor to be evaporated, which is heated up by means of steam admitted into the chamber. The liquor in the smaller tubes, being acted upon by comparatively greater heating surface, will attain a higher temperature than that in the large tube, and consequently will ascend in the former and descend in the latter, and thus an effective circulation in the liquor to be evaporated will be secured.—H. A.

Improved Method of and Means for Charging Materials into Apparatus such as Cupolas, Blast Furnaces, Lime Kilns, Scrubbers, and Absorption Towers. W. L. Wise, London. From Solvay and Co. Eng. Pat. 10,721, July 10, 1890. 8d.

THE object of this invention is the placing of materials in the above apparatus in any desired way, thus, for instance, distributing them uniformly, irrespective even of size and density of the particles, all over the section of the apparatus.

The appliance consists of a charging cone, the periphery of whose base is formed by a curve, the shape of which is varied according to the desired purpose. Where uniform charging is desired, the curve is a spiral "such that any two radii forming a constant angle between them shall describe

IMPROVED CHARGING CONE.

in their rotation two circles, the difference in diameter between which is constant. Each portion of the spiral corresponding to a constant angle at the centre thus generates a constant annular surface." The equation of this spiral is $r = a\sqrt{\theta}$, where r is the radius vector (varying from 0 to the radius of the furnace), a the radius of the section of the furnace, and θ the angle formed between the radius r and the initial radius.

The charge is tipped over the cone, and in falling is distributed all over its periphery; in the same time the cone makes a revolution, and the charge is thus equally sprayed over the surface of the kiln.—H. A.

Improvements in Reducing or Disintegrating Apparatus, more especially intended for Disintegrating Superphosphates and other similar Substances. P. U. Askham and W. Wilson, Sheffield. Eng. Pat. 11,474, July 22, 1890. 8d.

FOR disintegrating superphosphates two or more hollow drums are arranged one above the other, and are capable of being rotated in the same or in opposite directions in close proximity to, but not in actual contact with, reticulated or perforated concave hinged flaps, the inner radius of which corresponds nearly with that of the exterior periphery of the drums. Means are provided for oscillating these flaps in opposite directions. The coarse material to be disintegrated is fed into a hopper at the top of the machine, and falls into the space between the interior of the upper flap and the periphery of the drum, and the flap being made to move towards the revolving drum the material becomes squeezed and abraded. At the same time the lower flap is receding from the other drum, and is receiving into the similar space between it and the drum the material from the upper flap to be further disintegrated. The degree of fineness to which the material can be reduced is regulated by the adjustment of the space between the flaps and drums, and by the size of the reticulations.—E. S.

Improvements in or connected with Rotative Furnaces or Kilns for Treating and Recovering Waste Gases from Raw or partially Raw Materials, used more especially and for Example in the Manufacture of Cement. L. Johnstone, Newcastle-on-Tyne. Eng. Pat. 14,380, September 12, 1890. 8d.

See under IX., page 771.

* Any of these specifications may be obtained by post, by remitting the cost price, plus postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d.	3d.
Above 8d., and not exceeding 1s. 6d.	1d.
" 1s. 6d., " " " 2s. 4d.	1½d.
" 2s. 4d., " " " 3s. 4d.	2d.

Improvements in the Production of Cold and Ice, and in Apparatus therefor. E. J. Hardy, New York, U.S.A. Eng. Pat. 18,596, November 18, 1890. 8d.

This invention relates to that class of ice machines in which water is evaporated by being subjected to a vacuum, and the vapour brought into contact with sulphuric acid or other absorbing liquid. The improvements embrace the insertion of the pump cylinder to almost its entire length in the acid of the closed absorbing chamber, and causing it to extract air and vapour from that as well as from the freezing chamber, at the same time that a regulated supply of the acid is injected in the form of spray. The acid and vapours are pumped into a receiver, whence the air and vapour escape, whilst the acid is returned to the absorbing chamber. It is claimed that by this arrangement it becomes practicable to use one pump only for the double purpose of maintaining the vacuum and distributing the acid, whilst all working joints are effectually sealed by liquid. A diagram sketch indicates the principle of the arrangement, and there are eight claims.—B.

Improvements in Pressure Filters. J. Oxley and G. Sellars, Wombwell. Eng. Pat. 1717, January 30, 1891. 8d.

This invention relates to those filters which receive the water direct from the main, and which in some cases is under considerable pressure.

A lower metal box of a circular form has the lower part projecting and screwed for attachment to the supply pipe, and is provided with a suitable tap for drawing off the filtered water. The upper part of the box has an annular flange, through which pass several vertical bolts which secure in position a glass cylinder standing on the circular flange, and having within its lower end a perforated plate which acts as a lid to the circular box. The lower end of a vertical pipe is screwed into the centre of the circular box, and extends centrally up within the cylinder, to which it conducts the water to be filtered, its upper end being closed by a perforated cap, which can be adjusted by a spindle passing through a stuffing-box on the top cylinder cover, and by which means the various filtering media placed in the glass cylinder are held in the required position and at the necessary compression.—E. S.

Improvements in Evaporating Apparatus. S. M. Lillie, Philadelphia, U.S.A. Eng. Pat. 7187, April 25, 1891. By Internat. Conv. September 26, 1890. 8d.

This patent refers to various arrangements and combinations of the details of parts of evaporating apparatus, the main features of which consist in an evaporating chamber fitted with horizontal heating tubes. These pass at one end through the wall of the chamber into a steam space whilst their other ends are kept within the chamber and are closed except for a small hole in each for the escape of air or steam. The concentrating liquor is allowed to descend from overhead in thin layers over the outer surface of the tubes, where evaporation takes place. The concentrated liquor runs off below and may be returned by means of a pump to the overhead tank for further treatment. The vapour is drawn off by the vacuum pump or, where the apparatus is used in multiple effect the vapour is led into the steam space of the next chamber for heating the tubes and so on. The concentrated liquor is also in that case made to travel from one chamber to the other until the operation is concluded. For details the specification should be consulted, with its four sheets of drawings and 11 claims.—B.

Vacuum Evaporating Apparatus. H. Burgess, Royer's Ford, and C. D. Davis, Washington, U.S.A. Eng. Pat. 7704, May 4, 1891. 8d.

This refers essentially to arrangements of parts of evaporating apparatus in which a number of shallow vessels or dishes are superimposed one upon the other within a vacuum chamber, the liquid covering the floor of each vessel in a thin layer and overflowing into the next lower

one. Each dish is provided with a double bottom, heated by steam, and an additional steam coil is placed just above the level of the liquid in each, suitable pipes being arranged for the steam and condensed water. There are two sheets of drawings and four claims.—B.

Improvements in Evaporating Apparatus for Concentrating Liquids. W. P. Thompson, Liverpool. From Wirth and Co., Frankfort-on-Maine, Germany. Eng. Pat. 7867, May 7, 1891. 6d.

This apparatus consists of a horizontal cylindrical evaporating vessel in which a tubular heating contrivance is kept revolving. The horizontal tubes are fitted with both ends into circular steam chambers with central hollow trunnions, which project through glands in the lower part of the end plates of the evaporating vessel, the vessel being partly filled with the concentrating liquid. During each revolution the heating pipes rise above the level of the liquid and dip into it again, thus acting as stirrers, whilst the trunnions serve as inlet and outlet for the steam and condensed water. There is one sheet of drawings and one claim.—B.

Improvements in Evaporating Apparatus for Concentrating Liquids of a Pulpy Nature. W. P. Thompson, Liverpool. From Wirth and Co., Frankfort-on-Maine, Germany. Eng. Pat. 7869, May 7, 1891. 8d.

A TROUGH-SHAPED receptacle for containing the pulpy matter has within it a hollow rotating shaft, which is provided along its entire length in the trough with hollow fan-shaped stirrers arranged in pairs at right angles, and secured to the shaft by screwed bolts. Steam for heating enters through a pipe at one end and traverses the hollow shaft and stirrers, the water of condensation formed in the interior of the stirrers being discharged into the hollow space of the shaft, from which it runs off through a pipe, the whole apparatus being slightly inclined to accelerate its flow. Through the peculiar fan shape of the heating stirrers, the heating surfaces of which lie in the plane of rotation, the caking of the pulpy matter is avoided, the repeated friction between the matter and heating surfaces not permitting any particles to remain adhering to the stirrers.—E. S.

II.—FUEL, GAS, AND LIGHT.

The Causes of Explosions in Manufactories of Brown Coal Briquettes. R. Holtzwardt and E. von Meyer. Dingl. Polyt. J. 280, 185—190 and 237—240.

IN spite of numerous efforts to trace the cause of explosions in factories of briquettes made of brown coal and the adoption of sundry precautionary regulations, the frequency of such mishaps has continued, and the present investigation was undertaken to arrive at fuller knowledge and more efficient means of prevention. It may be classified under three heads:—

1. *Examination of the gases evolved during the process of manufacture.*—The samples were drawn in the ordinary way and analysed by the usual technical methods such as are described in Winkler's "Technische Gasanalyse." The analyses showed that neither in the drying ovens heated by steam nor in those with direct firing were the gases evolved in the least degree dangerous, the only combustible constituent, carbon monoxide, being present to the extent of 1 per cent. at the most, and generally in much smaller quantity. Moreover, those samples containing even this trifling amount showed a considerable increase in their content of carbon dioxide, whereby their inertness would be much enhanced. The fear of the possibility of danger from this source may be therefore dismissed.

II. *Examination of the gases evolved on heating brown coal.*—It has hitherto been assumed without experimental evidence that brown coal on drying evolves gases which behave in the manner of firedamp and readily give rise to explosions. The authors put this hypothesis to the proof by drawing dry air free from carbon dioxide slowly over brown coal heated to known temperatures and analysing the gases given off. They found that no appreciable amount of carbon monoxide or hydrocarbons such as methane was evolved. With coal dust, on the other hand, a considerably larger quantity was given off, 9 grms., when heated to 250°–280° C., yielding 349 cc. of methane and 127 cc. of carbon monoxide, mixed, however, with 920 cc. of carbon dioxide, the presence of which could not fail to diminish any tendency to explosion there might be very appreciable. No relation could be deduced between the composition of the coal and the nature of the gases obtained from it. An experiment upon a sample first heated alone and then with 2 per cent. of pyrites added showed that the addition of the latter, though increasing the rapidity of the oxidation, had no tendency to cause the evolution of combustible gases.

III. *The conditions of explosion of brown-coal dust.*—As the foregoing investigations had shown that there was no possibility of the occurrence of an explosion from evolved gases under normal conditions of working, it was evident that the cause must be looked for under conditions other than normal, such as those obtaining when the ignition of a portion of the fuel had actually occurred. Further, as it had been proved that combustible gases were not evolved in appreciable quantity, the conclusion was reached that the explosive material must be coal dust; it being well known that coal dust requires a high temperature for ignition and is ignited more easily when in rapid motion than when at rest.

Experiments were first tried on a considerable scale. A vessel of sheet iron was filled with coal dust and placed over a lighted forge. The bottom of the vessel could be withdrawn and its contents allowed to fall into the forge, thus reproducing to some extent the conditions of explosion mentioned above. The result was, however, negative, a fact which the authors explain by supposing that the source of heat was insufficiently intense to produce that rapid ignition which develops into an explosion.

A second series of experiments was therefore made with the apparatus shown in the figure.

APPARATUS FOR TESTING THE EXPLOSION OF COAL DUST.

The explosion tube E has a capacity of about 50 cc. and is provided with two platinum wires *i, i'* fused in, between which sparks from an induction coil can be passed; the right-angled tube *m* by which it is closed dips into water; the air in the bottle A can be put under pressure (measured by the gauge D) by means of the vessel C, filled with water and communicating with B, which has a capacity of about 3 litres. Communication between B and A and A and E can be made and cut off by means of the screw-clip *H1* and the stopcock *H2*. The quantity of dust used for each test is about 0.18 gm. It is projected into the explosion tube by suddenly opening the cock *H2* when the air in A is under pressure. The behaviour of some of the samples tested is given in the following table:—

No. of Sample.	Pressure of Air in Cms. of Mercury.				General Results.
	2.	3.	4.	5.	
	Explosion occurred.				
1	Twice not at all, once very weak.	Once not at all, once weak.	Twice not at all.	Not at all.	Tendency to explode very small.
4	Twice very strong.	Twice very strong.	Twice very strong.	Twice very strong.	Exploded at every trial.
6	Twice not at all, once weak.	Twice fairly strong.	Twice fairly strong.	Twice fairly strong.	Sample possessed considerable explosive tendency: 7 explosions out of 9 trials.

No relation could be traced between the tendency of the samples to explode and their ultimate composition.

The appearance of the explosion differed notably in different cases; when weak its course could be traced; when strong it appeared instantaneous throughout the tube.

The apparatus, though failing to solve many of the matters under consideration, is still of practical value, as by its means the comparison of one sample with another in respect of their explosive tendencies can be readily performed. It is noteworthy that the rapid motion of the coal dust is *essential* for its ignition; mere shaking of the tube even when testing the most explosive sample failed to give any explosion. An experiment with a mixture of 10 per cent. of carbon monoxide and 90 per cent. of air (which is almost explosive on its own account) gave an explosion that was not perceptibly stronger than when air alone was used.

From these results it is plain that the real cause of explosion in factories of brown-coal briquettes is the coal dust, and that the danger from this source only becomes grave under abnormal conditions of working where the ignition of a considerable quantity of the fuel has already taken place.

The explosion, however begun, may be considered to take place in two stages: in the first, the expansion of the gaseous products of combustion evolved suddenly by the ignition of the coal dust in itself constitutes an explosion; in the second, the combination of a portion of these products that are imperfectly oxidised (such as carbon monoxide or hydrocarbons) with the oxygen of the air will give a secondary explosive effect.

To this paper Meyer appends the following remarks:—Steam-heated drying ovens are naturally safer than those fired direct. Ventilation is an evil rather than a good, as it supplies any fuel incipiently alight with the necessary air without which it might well become extinct. The elevators

and travelling apparatus of all descriptions being those parts of the plant likely to contain most dust in motion are the most dangerous; consequently the shorter the distance from drying oven to storage room the safer the works.

—B. B.

Explosions of Coal Dust in Artificial Fuel Factories. Dingl. Polyt. J. **280**, 273.

Two accidents due to the explosion of coal dust are described in the *Jahresbericht d. k. preuss. Gewerbräthe für 1888*. At the Reichenwald works an explosion of coal dust took place in the dried coal store room whilst the operations were in full progress, with the result that the front of the drying house was violently blown out and a considerable conflagration occurred in the factory. At Fürstenberg on the Oder, where the works are entirely built of stone and iron, a similar explosion occasioned no damage, either to the workmen or to the buildings. The ignition of the coal dust appears to have commenced in the lowest feeding screw belonging to the drying room elevator, and to have spread forwards to the store room and backwards to the two drying houses. Five explosions followed in quick succession in different parts of the works, the detonation being strongest in the store room, and in a few minutes all the chambers containing dry coal dust were on fire.

These accidents afford further proof of the well-known fact that coal dust is itself a dangerous explosive, the presence of which must be guarded against in factories, mines, &c. by thorough ventilation and other protective measures.—S. B. A. A.

Investigation on the Slow Combustion of Gaseous Mixtures. A. Krause and V. Meyer. *Annalen*, 1891, **264**, (i) 85—116.

The action of heat on the gradual combustion of gaseous mixtures has been studied with the view of ascertaining whether gaseous mixtures such as ordinary electrolytic gas, when heated to a temperature below the ignition temperature of the mixture, show similar regularities in the relation of the time of heating to the quantity of water formed by the combination of the gases as is observed in the case of hydrogen and chlorine when exposed to light. Very small quantities of air if present with the mixture of hydrogen and oxygen exercise so much influence on the combination of the gases when heated that it was found impossible to work out the above relationship without the gases being in a state of perfect purity. The two gases combine together when heated in a glass tube to 305 °C., in presence of mercury, but in absence of mercury they can be heated for days to this temperature without any combination occurring. At 448 °C. however, they combine slowly, more rapidly at 518 °C. Carbon monoxide and oxygen combine in considerable quantities to form carbon dioxide at 448 °C. The temperature at which the above two mixtures explode is between 518 °C. and 616 °C.

The results of experiments made under varying conditions with most carefully purified electrolytic gas fail to show any relationship between the time during which the mixture is heated and the quantity of water formed. With bulbs of as nearly as possible the same size and heated under exactly the same conditions, the percentage composition of the mixture that had entered into combination was found to vary very much—differences of more than 25 per cent. being found in parallel experiments. The cause of the irregularity is traced by the authors to dissimilarities in the surface of the bulbs employed, although they were made as much alike as possible both in size and form, they propose to eliminate this effect in their further experiments on the subject, by etching the inside of the bulbs so that the surface to which the gases are exposed is completely roughened, thereby reducing the proportional effect of the small differences referred to. Full details of the plan adopted for the purification of the electrolytic gas and of the method of experiment employed are given.—C. A. K.

The Resinous (Soluble) Constituents of Coal. P. Liepmann. *Zeits. f. Berg. Hütten u. Salinenw.* 1891, **36**, 26.

See under III., page 753.

The Rate of Explosions in Gases. H. B. Dixon. Lecture, Royal Inst., June 12, 1891.

WHILE Berthelot, associated with Vieille, was measuring the rate of the "explosion-wave" for various mixtures of gases, Mallard and Le Chatelier continued the study of the preliminary phenomena of explosion which precede the formation of the "wave." They showed, by photographing on a revolving cylinder, (1) that when a mixture such as nitric oxide and carbon bisulphide is ignited at the open end of a tube, the flame travels a certain distance (depending on the diameter and length of the tube) at a uniform velocity; (2), that at a certain point in the tube vibrations are set up which alter the character of the flame, and that these vibrations become more intense, the flame swinging backwards and forwards, with oscillations of increasing amplitude; and (3) that the flame either goes out altogether, or that the rest of the gas detonates with extreme velocity. Again, when a mixture of gases was fired near the closed end of the tube, they found the velocity of the flame regularly increased, as far as their instruments were able to record the rapidly increasing pace.

Mixtures of coal-gas with air, and of firedamp with air, show phenomena of the first and second kind. Ignited at the open end of a tube, these mixtures burn at a uniform rate for a certain distance, and then the flame begins to vibrate. The vibrations acquire greater or less velocity according to the nature of the mixture and the conditions of the experiment, but the third régime of uniform maximum velocity is not set up. In narrow tubes the explosion soon dies out.

The phenomena studied by Mallard and Le Chatelier have been observed on a large scale in explosions in coal mines. It has been noticed that little damage was caused at the source of an explosion, and for a distance varying from 50 to 80 yards from the origin of the flame, while beyond that distance fall of roof, broken tubs, and blown-out stoppings have testified to the violence exerted by the explosion. Great as the destruction is which an explosion of firedamp and air causes in a mine, it is fortunate that these mixtures do not detonate.

Passing on to Berthelot's researches on the régime of detonation, the author briefly summarises the results arrived at.

The actual velocities of explosion are compared by Berthelot with the mean velocity of translation of the gaseous products of combustion, supposing these products to contain all the heat that is developed in the reaction. For instance, we know the total heat given out when hydrogen and oxygen combine. If this heat is contained in the steam produced, we can calculate what its temperature must be if we know its heat capacity. And if we know the temperature of the steam, we can calculate the mean velocity with which the molecules must be moving. Now Berthelot supposes that the heat is all contained in the steam produced. He assumes that the heat capacity of steam is the same as the sum of those of its constituents, and he supposes, moreover, that the steam is heated at constant pressure. Making these assumptions, he calculates out the theoretical mean velocity of the products of combustion of various mixtures, and finds a close accordance between these numbers and the explosion rates of the same mixtures. He concludes that the explosive wave is propagated by the impact of the products of combustion of one layer upon the unburnt gases in the next layer, and so on to the end of the tube at the rate of movement of the products of combustion themselves. If his theory is true, it accounts not only for the extreme rapidity of explosion of gaseous mixtures, and gives us the means of calculating the maximum velocity obtainable with any mixture of gases, but it also affords us information on the specific heats of gases at very high temperatures, and it explains the phenomena of detonation, whether of gases or of solid or liquid explosives.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

The Formation of Petroleum and Solid Paraffin.
R. Zaloziecki. Dingl. Polyt. J. **280**, 69—72, 85—89,
and 133—136.

THIS article consists of a lengthy physical and chemical argument in favour of the modern view that petroleum and paraffin owe their origin to animal sources: that they are formed from animal remains in a manner strictly analogous to that of the formation of ordinary coal from wood and other vegetable debris. For geological as well as chemical reasons, the author holds that Mendeleeff's theory of their igneous origin is untenable, pointing out that the hydrocarbons could not have been formed by the action of water percolating through clefts in the gradually solidifying crust until it reached the molten metallic carbides, as these clefts could only occur where complete solidification had taken place, and between this point and the metallic stratum a considerable space would be taken up by semi-solid slag-like material which would be quite impervious to water. Under the conditions, too, existing beneath the surface of the earth, such polymerisation as is necessary to account for the presence of the different classes of hydrocarbons found in petroleum is scarcely credible.

On the other hand it is to be specially noticed that, with a few unimportant exceptions, all bituminous deposits are found in the sedimentary rocks, and that just as these are constantly changing in composition, so the organic matter present changes, there being a definite relationship between the chemical constitution of the petroleum and the age of the strata in which it is found. It is almost certain that in the most recent alluvial formations no oil is ever found, its latest appearance being in the rocks of the tertiary period, the place where the solid paraffin is almost exclusively met with; thus helping to show that the latter has been formed from the decomposition of the oil, and is not a residue remaining after the oil has been distilled off. To this conclusion the fact also strongly points, that the paraffin is much simpler in constitution, purer, and often of far lighter colour than the crude oil, which could not be the case if it were the original substance.

On examining by the aid of a map the position of the chief oil-bearing localities it will be noticed that the most prolific spots follow fairly accurately the contour lines of the country, so that at one time they formed in all probability a coast line whereon would be concentrated for climatic reasons most of the animal life both of the land and sea. During succeeding generations their dead bodies would accumulate in enormous quantities and be buried in the slowly depositing sand and mud, till owing to the gradual alterations of level the sea no longer reached the same point. This theory is borne out by the fact that oil deposits are usually found in marine sediments, sea-fossils being frequently met with. The first process of the decomposition of the animal remains would consist in the formation of ammonia and nitrogenous bases, the action being aided by the presence of air, moisture, and micro-organisms, at the same time owing to the well-known antiseptic properties of salt, the decomposition would go on slowly, allowing time for more sand and inorganic matter to be deposited. In this way the decomposing matter would be gradually protected from the action of the air and finally the various fatty substances would be found mixed with large amounts of salt, under considerable pressure, and at a somewhat high temperature. From this adipocere, fatty acids would be gradually formed, the glycerol being washed away, and finally the acids would be decomposed by the pressure into hydrocarbons and free carbonic acid gas. That many of these hydrocarbons would be solid at ordinary temperatures, forming the so-called mineral wax, which exists in many places in large quantities, is much easier to imagine, in the light of modern chemical knowledge, than that the fatty acids were at once split up into the simpler liquid hydrocarbons, to be afterwards condensed into the more complex molecular forms of the solid substance.

In this way from animal matter are in all probability formed the vast petroleum deposits, the three substances, adipocere, ozokerite, and petroleum oil being produced in chronological order, just as lignite, brown-coal and coal are formed by the gradual decomposition of vegetable remains.

—F. H. L.

Petroleum Ether. F. Evers. Pharm. Zeit. 1891. **36**, 246.

THE author has recently examined several samples of petroleum ether which have the specific gravity required by the Pharmacopœia, but which boiled between 32° and 110° C., and which gave a distinct smell of benzaldehyde when treated with nitric acid. These petroleum ethers, technically known as "hydrocarbon," are obtained as a by-product in the compression of oil-gas. They contain up to 50 per cent. of benzene and toluene, together with olefines and nauseous sulphur compounds. When shaken with strong sulphuric acid the objectionable smell due to the sulphur compounds is removed and the benzene can be recovered after this treatment by shaking the separated layer of hydrocarbons with lime-water and then distilling with steam. It is recommended that all samples of petroleum ether obtained from such sources as the above should be carefully tested for benzene both by the boiling point and by the nitrobenzene reaction.—C. A. K.

The "Resinous" (Soluble) Constituents of Coal. P. Siepmann. Zeits. f. Berg. Hütten u. Salinenw., 1891. **36**, 26.

THE coal examined was a Westphalian gas-coal having the following composition:—

C.....	80.31
H	5.70
O }	12.94
N }	1.25
S.....	100.00

By treating the coal with different solvents, viz., ether, alcohol, and chloroform, three products differing both in properties and in composition were isolated.

The product extracted by means of ether amounts to 0.3 per cent. and forms a hard, yellow-brown resin, having an aromatic smell. It does not redissolve completely in ether. The portion that is soluble in ether is sticky at the ordinary temperature, at 35° C. it forms a thin liquid and begins to decompose at 100° C. The following analytical results were obtained:—I. of the crude product; and II. of the product purified by redissolving in ether:—

	I.	II.
C.....	84.82	78.74
H	10.51	9.64
O.....	4.67	11.62
	100.00	100.00

The alcoholic extract (obtained after completely exhausting the sample with ether) amounted to 0.25 per cent. It consists of a dark brown resin which when pulverised forms a light brown powder: it has an aromatic smell, melts at 48°—50° C. and begins to decompose at 100° C. An analysis of this product is given below.

The chloroform extract amounted to 0.75 per cent., and consists of a dark brown pitch-like mass, having a smell of coal-tar. It begins to melt at 60° C., melts completely at 85° C., and decomposes at 145° C. The substance extracted by means of ether from two samples of coal was identical, a fact which, in the opinion of the author, may justify one in the opinion that it is an individual and pure body.

The following analytical data are given:—

	Alcohol Extract.	Carbon tetrachloride Extract.	Coal after Extraction.
C	72.52	78.82	74.00
H	10.08	8.76	1.77
O	17.40	11.97	2.109
N	1.000	
S	2.65	
	100.00	100.00	100.00

According to Rammelsberg ("Mineralchemie") "a few per cent. of a dark resin can be extracted from cannel coals by means of alcohol, ether, and especially of carbon bisulphide, which resin is the cause of the caking of these coals." The experiments of the author, however, go to show that the caking power of such coals is not due to, although influenced by the presence of these soluble resinous constituents.—C. A. K.

PATENT.

Improvements in the Purification of Coal Tar, and Rendering same a suitable Paint or Coating for Iron and Steel Structures. T. H. Davis, Manor Park, and A. H. Davis, Rock Ferry. Eng. Pat. 10,976, July 15, 1890. 4d.

The tar is washed by agitation with a solution of copper or zinc sulphate, and then with clean water. Sulphuretted hydrogen, &c., can by these means be removed.—E. G. C.

IV.—COLOURING MATTERS AND DYES.

A Violet Colouring Matter from Morphine: the Formula of Pseudomorphine. P. Cazeneuve. Bull. Soc. Chim. 1891, 5, 857-863.

A violet colouring matter is formed, together with other substances, by boiling for 100 hours in a reflux apparatus a mixture of morphine (7 grms.), *p*-nitrosodimethylaniline hydrochloride (5 grms.), and alcohol (500 cc). The solution gradually assumes a red brown colour, and a quantity of *N*-trimethyldiamidoazobenzene separates in a crystalline state. After filtering from the latter, the alcoholic solution is evaporated to dryness, and the residue boiled with water, a deep purple coloured solution being so obtained. This solution, which contains at least two colouring matters, is evaporated almost to dryness, acidulated with hydrochloric acid, and then rendered alkaline with sodium hydrate, the colouring matters being precipitated and the unchanged morphine remaining in solution. The precipitate is collected on a filter, washed with dilute sodium hydrate, dried, and extracted in the cold with amyl alcohol, which dissolves out a violet colouring matter, and leaves in the residue a blue colouring matter of mixture of colouring matters. The violet colouring matter is obtained in a pure state on evaporating the amyl alcohol. Its platinumchloride has the formula $\text{PtCl}_4 \cdot \text{C}_{17}\text{H}_{19}\text{NO}_3 \cdot 2\text{HCl}$, and has the characteristic properties of the platinumchlorides of the majority of alkaloids. The colouring matter, of which the free base has the formula—

forms an amorphous mass with a bronze-like lustre; it is sparingly soluble in water, freely so in alcohol, its alcoholic solution being strongly dichroic; its green coloured solution in concentrated sulphuric acid becomes successively blue and violet on dilution with water; it dyes silk, wool, and gun-cotton, but is not fast to light.

The constitution of the violet colouring matter cannot be expressed on the quinone-anilide type, since codeine, the methyl ether of morphine, gives a similar colouring matter without any separation of methyl alcohol taking place. Nor does the fact of morphine being a tertiary alcohol assist the solution of the problem, as tertiary alcohols in general interact only with great difficulty with *p*-nitrosodimethylaniline. It may, therefore, be assumed that the constitution of the colouring matter in question is analogous to that of Bind-scheller's green; thus—

The constitution of the violet colouring matter cannot, however, be explained until more is known about the constitution of morphine itself, in particular with regard to the position in the molecule of the same of the two atoms of hydrogen which are so readily removed by oxidation. These two hydrogen atoms occupy, no doubt, the position in the molecule to which the two free bonds of the residue—

attach themselves.

Although pseudomorphine could not be detected amongst the products of the reaction of *p*-nitrosodimethylaniline on morphine, it is highly probable that it is formed, according to the equation—

its absence in the final products being due to its combining with the nitrosodimethylaniline or entering into secondary reactions.

Whatever the constitution of the violet colouring matter may be, its formation elucidates the nature of pseudomorphine. For, assuming that pseudomorphine is produced, as Hesse considers, by the dehydrogenation of morphine, the formula of the violet colouring matter would be—

Hesse assigning to pseudomorphine the formula—

instead of $\text{C}_{17}\text{H}_{19}\text{NO}_4$, the formula given to it by Schützenberger.

On heating the violet colouring matter, however, to 130°, no change is produced; the molecule of H_2O is presumably, therefore, in a different state from water of crystallisation. Again, if pseudomorphine have the formula—

given to it by Polstorff (this Journal, 1886, 616), it should yield with nitrosodimethylaniline either a safranine or a compound of the formula—

As it yields neither, and as, moreover, one molecule of morphine alone interacts with one molecule of nitrosodimethylaniline, Polstorff's formula is evidently incorrect.

Morphine violet is the first true colouring matter obtained from the natural alkaloids, the Morphine blue of Chastaing and Barillot (Compt. Rend. 105, 1012) not being a colouring matter properly so-called.—E. B.

Hydrazone Derivatives of β -Naphthoquinone. E. Noelting and E. Grandmougin. Bull. Soc. Chim. 1891, 5, 863—869.

The constitution of the azo-derivatives of β -naphthol and of their isomerides, the hydrazones of β -naphthoquinone, has been much discussed, the following formulae being, for instance, variously assigned to the compound produced by the action of phenylhydrazine on β -naphthoquinone:—

A study of the dyestuff derivatives of the hydrazones of β -naphthoquinone, more particularly of the sulphonic acid derivative of the phenylhydrazone (see following abstract), led the authors to conclude that such bodies were azo-compounds and not true hydrazones. Facts in support of this view are given below.

If the compound of phenylhydrazine with β -naphthoquinone be a hydrazone, it should not react with diazobenzene chloride, whereas, if it be an azo-compound, it should be capable of doing so. To decide this point, β -naphthoquinone-phenylhydrazone was first prepared by the method of Zincke and Bindewald (this Journal, 1885, 395), but with the use of as little acetic acid as possible, namely, 10 times the weight of the β -naphthoquinone; a 50 per cent. yield was obtained, a considerable portion of the phenylhydrazine becoming oxidised, probably into benzene, by the quinone, which is simultaneously reduced to a corresponding extent, to dinaphthoquinol, $\{\text{C}_{10}\text{H}_7(\text{OH})_2\}_2$, a compound separating in beautiful colourless needles on the acetic acid mother-liquor being diluted with water. Zincke and Bindewald's description of the properties of the chief product of the reaction was confirmed, the authors observing in addition that the compound, like the compound from β -naphthol and diazobenzene, can be sublimed, orange needles with a green surface-lustre being thus obtained; it is insoluble in alkalis in the cold, and but slightly soluble on heating; it dissolves easily, however, in the theoretical quantity of sodium methylate or ethylate, yielding a dark red solution, which remains clear on dilution with water. This alcoholic solution contains the sodium salt of the compound, and, according as it is represented as a hydrazone or an azo-derivative, has either the constitution—

To decide between these formulae the ethyl ether was prepared and reduced; the reduction products were found to be aniline and β -amido-naphthol ether, without a trace of ethylaniline. This result is in favour of the second formula, though it is just possible that an intra-molecular change is brought about, thus:—

Phenyldisazo- α -naphthol cannot well be prepared by acting on an alkaline solution of β -phenylazo- α -naphthol, owing to the feeble solubility of the latter. It was, however, readily obtained on adding the necessary amount of diazobenzene chloride to a solution of the β -azo compound in a slight excess of sodium ethylate. After standing 12 hours, the separation of the disazo-compound was complete. It was filtered off and crystallised from a mixture of alcohol and chloroform, and was then obtained in the form of brown needles with a bronzy green reflex. The compound is in every respect identical with the body prepared by Krohn (this Journal, 1889, 116) by the action of 2 mols. of diazobenzene on α -naphthol. (The melting point of Krohn's compound, after recrystallisation, was found to be 193°.) To further prove the identity of the two preparations, the acetyl derivative (melting point 159°—160°) and ethyl ether (melting point 121°) were prepared.

As Krohn (*loc. cit.*) has shown that the formula of phenyldisazo- α -naphthol is—

that of the phenylhydrazone compound of β -naphthoquinone must be—

This formula explains the feeble acid character of the compound, other *o*-hydroxyazo-compounds, such as phenyl-azo-*p*-eresol—

and phenyldisazophenol—

being very sparingly soluble in aqueous alkalis.

If the hydrazone formula—

be assigned to Krohn's disazo-compound, a similar formula must be given to phenyl-azo-*p*-eresol, which is not in conformity with the behaviour of its ethers (this Journal 1890, 1123).

Lastly, if the phenylhydrazine compound of β -naphthoquinone were a hydrazone, it should react with hydroxylamine and yield an oxime—

The authors could not, however, obtain such a compound. —E. B.

Some α -Hydroxyazo Derivatives of α -Naphthol. E. Noetting and E. Grandmougin. Bull. Soc. Chim. 1891, 5, 869—873.

HAVING shown that the phenylhydrazine compound of β -naphthoquinone is an α -hydroxyazo derivative of α -naphthol (see preceding abstract), the authors prepared some derivatives of that compound for the purpose of comparison, with respect to their tinctorial properties, with the isomeric p -substituted α -naphthol compounds.

p-Sulphophenylazo- α -naphthol—

is obtained by suspending β -naphthoquinone (1 molecular proportion) in 10 times its weight of glacial acetic acid and adding a cold, concentrated aqueous solution of sodium p -phenylhydrazine-sulphonate (1 molecular proportion). After standing for 24 hours, the red precipitate formed, which consists of the sodium salt of the above acid, is filtered off. Its yield is not satisfactory, part of the naphthoquinone remaining in solution in the acetic acid, and part being decomposed as in the preparation of β -phenylazo- α -naphthol (preceding abstract). It dyes wool and silk scarlet from an acid bath. It is isomeric with Orange 1.—

which is produced by the action of p -diazobenzene sulphonic acid on α -naphthol or of p -phenylhydrazine sulphonic acid on α -naphthoquinone. The azo dye—

is also a scarlet; the α -naphthylamine compound—

a wine-red; its β -naphthylamine isomeride, a scarlet.

The compound—

obtained from β -naphthoquinone and 1:4-naphthylhydrazine sulphonic acid is a red-purple, whilst the isomeric compound prepared from α -naphthol and 1:4-diazonaphthalene sulphonic acid—

is a brown (Fast brown).

In general, the α -hydroxyazo derivatives of α -naphthol are reds, the p -hydroxyazo derivatives yellow-browns. The same difference appears in the shades yielded by the carboxy derivatives of the two series, the compound—

prepared from m -phenylhydrazine carboxylic acid and β -naphthoquinone dyes a bluish-red on wool, silk, and chrome-mordanted cotton, whilst the p -isomeride—

dyes brown on the same.—E. B.

The Disazo Derivatives of α -Naphthol: A Transposition. E. Noetting and E. Grandmougin. Bull. Soc. Chim. 1891, 5, 873—879.

DIAZO-BENZENE chloride acts on the phenylhydrazone of β -naphthoquinone yielding phenyldisazo- α -naphthol, a compound which is also produced by the action of diazo-benzene chloride on p -phenylazo- α -naphthol (see preceding abstract: Hydrazone derivative of β -naphthoquinone). The p -sulphoxy and m -carboxy derivatives of the phenylhydrazone of β -naphthoquinone react similarly with diazo-benzene chloride yielding respectively:—

and

but a curious transposition takes place when *p*-diazobenzene sulphonic and *m*-diazobenzene carboxylic acids act on *p*-phenylazo- α -naphthol, the compounds—

and

being respectively then produced along with phenyldisazo- α -naphthol, according to the equation—

The compound—

is easily soluble in boiling water, and separates in an amorphous state on cooling. It dyes animal fibres red-brown. Its sulphonic acid derivative, namely—

which is obtained, as described above, was separated by filtration from the insoluble phenyldisazo- α -naphthol simultaneously formed. The disulphonic acid is not precipitated by the addition of acids to its alkaline solution, and as it could not therefore be readily obtained pure, an analysis was not made but the dyeing properties of the compound alone investigated, being compared with those of the compound obtained from 2 mols. *p*-diazophenyl-sulphonic acid and α -naphthol; the two preparations were thus found to be identical.

The earboxy compound—

crystallises in fine, brown needles and possesses feeble acid properties; it is soluble in hot aqueous alkalis. Its colouring power is slight, owing to its feeble solubility in water. The corresponding dicarboxy compound—

separates after some time from the phenyldisazo- α -naphthol which accompanies it, when the mixture of the two substances is dissolved in chloroform, and alcohol added. It is

easily soluble in alcohol, but cannot be crystallised from the same, and dissolves easily in alkalis with a red colour. On heating to 250° it darkens and decomposes at about 264°. A nitrogen determination was made, after precipitating it by acid from its alkaline solution, and the above formula confirmed. It was also prepared by the combination of α -naphthol with 2 mols. of *m*-diazobenzoic acid, and found to have the properties described. On chrome-mordanted cotton it dyes a pale dull red; on silk and wool in an acid bath, red-purple.

The authors notice that, in the preparation of *p*-phenylazo- α -naphthol from diazobenzene chloride and α -naphthol, a notable amount of phenyldisazo- α -naphthol is produced, a corresponding amount of α -naphthol remaining unchanged. This seems to have hitherto escaped observation.

It was thought possible for *o*-phenylazo- α -naphthol to be formed along with the above *p*-compound, but its presence could not be detected.—F. B.

The Relations of Eucharhodines to Indulines and Safranines.
F. Kehrman and J. Messinger. Ber. 24, 584—592.

Or the two formulae—

proposed for α -amidonaphthophenazine by Fischer and Hepp (this Journal, 1890, 602) and Kehrman (this Journal, 1890, 934) respectively, the former has been shown to agree better with the properties of the compound in question (this Journal, 1890, 1028). Both, however, appear to be possible, the forms which they represent being desmotropically related. This is proved to be the case by replacing by an alkyl, &c. group the movable hydrogen-atom which produces the tautomerism, stable isomerides of each type being then obtainable. The authors have succeeded, by the action of phenyl- α -phenylenediamine on hydroxynaphtho-imidoquinone, in synthesising *rosinduline*—

a compound of the second (imidoquinone) type. This was accomplished by heating under pressure a mixture of the bodies named with alcohol and acetic acid, 5 grms. of the imidoquinone yielding 2—3 grms. of rosinduline (this Journal, 1890, 601). To account for the resemblance between rosinduline and the safranines (the bitter taste of the salts of the same, for instance, amongst other points of similarity), it is suggested that the salts of rosinduline are derived from an unstable ammonium-base of the constitution—

Rosindone (this Journal, 1890, 602) was obtained on mixing, at the ordinary temperature, alcoholic solutions of equal molecules of hydroxynaphthoquinone and phenyl- α -phenylenediamine and acidulating with a few drops of acetic acid. It is proposed to change the name of this compound to "rosindulone," since the termination "indone" might lead to confusion with the ketoindene derivatives of the same name, the keto derivative of the "simplest" induline, namely, pheninduline, being in accordance with this proposed change, named "phenindulone."

Indulones were also prepared from chlorodihydroxyquinone and dihydroxythymoquinone and their physical properties determined.—E. B.

Synthesis of Methyl Indigo from p-Chloracet-toluide and p-Tolylglycine. H. Eckenroth. Ber. 24, 693.

When either *p*-chloracet toluide, or *p*-tolylglycine, is fused with potash (2 parts) in the manner described by Flimn and Heumann in their syntheses of indigo (this Journal, 1890, 281 and 1121), an orange-coloured mass is obtained, from which, on treatment with water and exposure to air, dimethyl-indigo separates. The reaction, in the case of *p*-tolylglycine, may be expressed by the following equation:—

Dimethyl-indigo is physically indistinguishable from ordinary indigo.

That the product of the above reaction is dimethyl-indigo is proved by its yielding *p*-toluidine on distillation with potash. (See also following abstract.)—E. B.

Non-Formation of an Indigo Derivative from p-Tolylglycine by Fusion with Alkali. K. Henmann. Ber. 24, 1346.

The author, in disagreement with H. Eckenroth (preceding abstract), finds that pure *p*-tolylglycine (made from pure *p*-toluidine) does not yield any indigo derivative when fused with potash.—E. B.

Diethyl- and o-Toluene-Indigo. K. Henmann. Ber. 24, 977—979.

Diethyl-indigo—

is obtained by fusing ethylphenylglycine (from chloroacetic acid and ethylaniline) with caustic potash in the manner previously described by the author (this Journal, 1890, 1121). It is probably identical with the compound obtained by Baeyer (Ber. 16, 2201) by reduction of diethylpseudosatin- α -oxime. It has a dark-blue colour, is slightly soluble in hot alcohol, and dissolves in aniline with a blue-green colour; the shades dyed by it and its sulphonic acid derivatives are grayer than those of indigo.

If instead of heating at 350° for a short time, the potash melt be kept at 280—330° for 15–20 minutes, ordinary indigo appears to be formed.

o-Toluene-indigo—

is produced by the action of potash on *o*-tolylglycine at 300–350°. It crystallises from hot aniline in fine, bronze prisms. The shades it dyes on cotton are a trifle greener than those of indigo; its disulphonic acid derivative, on the other hand, dyes wool a much redder shade than does indigo extract. The name *o*-toluene-indigo is adopted in

order to avoid confusion with the dimethyl-indigo, in which the hydrogen of the imido group is substituted by the methyl group.—E. B.

Adulteration of Cochineal-Red. E. Donath. Chem. Zeit. 1891, 15, 522.

A SAMPLE of cochineal-red of very poor appearance consisted entirely of an eosin lake of lead and alumina mixed with lead sulphate. It was insoluble in ammonia and left 88.5 per cent. of ash. Another sample, only distinguishable with difficulty from pure cochineal when placed side by side with it, consisted entirely of a barium lake of red Corallin. It was to a large extent soluble in ammonia, and on ignition left 74.5 per cent. of ash consisting of barium carbonate mixed with a little sulphate.—S. B. A. A.

The Technical Preparation of Phthalic Acid. H. Lüssens. Chem. Zeit. 1891, 15, 585.

According to the information to be found in text books, phthalic acid is prepared from naphthalene on the large scale by first converting the latter into the tetrachloro addition product, $\text{C}_{10}\text{H}_6\text{Cl}_4$, which is then oxidised with nitric acid. No details are to be found regarding the manufacture of phthalic acid or of its substitution products by the direct oxidation of naphthalene or of substituted naphthalenes, nor is anything to be found in the literature regarding the employment of oxidising agents other than nitric acid. As regards the direct oxidation of naphthalene, it is generally stated that both it and phthalic acid are completely burned to carbon dioxide and water by chromic acid mixture; that nitric acid acts directly upon naphthalene to produce mononitronaphthalene is, of course, well known. Despite these statements, it is well known to those interested in the preparation of the acid on the large scale, that in its manufacture for the preparation of the eosine and allied colours, by far the larger proportion is not obtained by the oxidation of the tetrachloride of naphthalene with nitric acid, but by the direct oxidation of naphthalene with chromic acid mixture. Sodium chromate is generally employed as the oxidising agent and not the potassium salt or potassium bichromate. According to Friedländer ("Fortschritte der Theoriefarben-Fabrikation," p. 137) phthalic acid is also prepared by the oxidation of the sulphonic acids of naphthalene and of naphthol either by means of nitric acid or of chromic acid mixture. The author compares the relative values of the old process with that generally employed in the aniline colour works, pointing out the decided advantages of the latter; but even the older method must, in his opinion, be a lucrative one with the present price of phthalic anhydride (7 marks per kilo. = about 3s. 6d. per lb.). As far as his experience goes, phthalic acid is not manufactured by the direct oxidation of naphthol as stated by Friedländer.—C. A. K.

Phthalic Acid. Fuchs. Chem. Zeit. 1891, 15, 735.

In reply to the paper by Lüssens on this subject (vide previous abstract) the author expresses his doubt as to whether phthalic acid can be successfully prepared by the direct oxidation of naphthalene with chromic acid, and states that his own experiments on the subject have not yielded favourable results. Reference is made to Hager's patent for getting the acid by treating naphthalene with nitric acid, and to Schützenberger's statement that it can be got by first preparing a solid tetrachloronaphthalene and then oxidising this with dilute nitric acid. In the former process, as is well known, mononitronaphthalenes result, and in the latter the yield of phthalic acid is but small, and tri-nitronaphthalene together with other nitrated products are formed, so that neither of them can be regarded as being of any commercial value. Were the yield of the acid by any of the processes in use anything like a theoretical one, the price should be at most 2 marks per kilo. instead of 6–7 marks. One great source of loss is that occurring in the conversion of the acid into the anhydride.—C. A. K.

PATENTS.

Improvements in the Manufacture of Colouring Matters. G. W. von Nawrocki, Berlin, Germany. From P. Böttiger, Lodz, Russia. Eng. Pat. 4415, March 5, 1884. Amended May 2, 1890. (Second Edition.) 6d.

ALREADY abstracted (this Journal, 1891, 131).—T. A. L.

Improvements in the Manufacture and Production of Colouring Matters from Dihydroxybenzoic Acid. J. Y. Johnson, London. From the "Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 12,356, August 7, 1890. (Second Edition.) 6d.

NITROSO-DERIVATIVES of tertiary aromatic bases, such as dimethylaniline, diethylaniline, methylbenzylaniline, and ethylbenzylaniline are condensed with symmetrical dihydroxybenzoic acid ($C_6H_3CO_2H:OH:OH = 1:3:5$) in an aqueous, alcoholic or acetic acid solution with the formation of dyestuffs. The dihydroxybenzoic acid is obtained by fusing *m*-disulphobenzoic acid with caustic potash (Barth and Lenhofer, *Annalen*, 159, 222). About 10 kilos. of dihydroxybenzoic acid are dissolved in 1,000 litres of water, heated to 70° C., and 12 kilos. of nitrosodimethylaniline hydrochloride gradually added. After standing about five hours the new colouring matter separates out as a crystalline precipitate, which is filtered off and washed with cold water. It may be purified by dissolving in dilute soda, filtering and precipitating with an acid. The colouring matters dye wool without a mordant, and the presence of a mordant does not alter the shade, so that these products may be used with mordant colouring matters, such, for instance, as Alizarin blue, giving much more brilliant shades.—T. A. L.

Improvements in and Relating to the Manufacture and Production of New Materials for the Preparation of Dyestuffs. J. Y. Johnson, London. From the "Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 12,386, August 7, 1890. (Second Edition.) 6d.

THE new substances are amido- and sulpho-derivatives of the naphthylglycolic acids (naphthoxyacetic acid) obtained by condensing α - or β -naphthol or their sulphonic acids with monochloro-acetic acid, nitrating these compounds and reducing the nitro-products thus formed. The amido-derivatives produced are capable of combining with diazo- or tetrazo-compounds to form new dyestuffs. In nitrating β -naphthoxyacetic acid, a better yield is obtained if the ether be employed, and the nitro-compound subsequently saponified. The α -nitro- β -naphthoxyacetic acid melts at 190°–192° C., crystallises in thick pale-yellow needles, slightly soluble in boiling water, more readily soluble in boiling acetic acid or alcohol. The α -amido- β -naphthoxyacetic acid is capable of forming an anhydride of the formula—

by the action of an acid which does not combine with diazo-compounds. It can be converted into the sodium salt of the acid by boiling for a short time with caustic soda solution.—T. A. L.

Improvements in the Manufacture and Production of New Diphenyl Derivatives, and a New Base for use in the Preparation of Dyestuffs. J. Y. Johnson, London. From the "Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 12,550, August 11, 1890. (Second Edition.) 6d.

A METHOD for obtaining *p*-diamido-di-*o*-phenoxyacetic acid ($CO_2H \cdot CH_2O \cdot (NH_2) \cdot C_6H_3 \cdot C_6H_3(NH_2) \cdot (OCH_2 \cdot CO_2H)$) from *o*-nitrophenoxyacetic acid, an anhydride being formed

as an intermediate compound, having probably the following constitution—

This is converted into the amido body by boiling with dilute caustic soda solution and precipitation with salt. On treatment with nitrous acid it yields a tetrazo-compound, which combines with phenols and amines to form colouring matters. The anhydride described is obtained by reducing *o*-nitrophenoxyacetic acid with zinc dust and caustic soda, in order to obtain the hydrazo-compound, and this, when added to strong hydrochloric acid, yields the anhydride. It may also be obtained from azo- or azoxyphenoxyacetic acid by reduction with stannous chloride.—T. A. L.

The Manufacture and Production of New Derivatives of Alizarin and its Analogues. B. Willcox, London. From the "Farbenfabriken vormals F. Bayer and Co.," Elberfeld Germany. Eng. Pat. 12,715, August 13, 1890. 6d.

THIS is an extension of Eng. Pat. 8725 of 1890 (this Journal, 1891, 537). The constitution of the *Alizarin-bordeaux* there described has been investigated, and found to be a tetrahydroxyanthraquinone. If the intermediate product formed in its manufacture, which is its sulphuric ether, be treated with ammonia instead of with caustic soda, a new colouring matter is obtained, giving bluer shades than *Alizarin-bordeaux*. The intermediate compounds from the various bordeaux from purpurin, flazopurpurin, anthrapurpurin, anthragallol, and also from ruffallic acid, may be treated with ammonia in a similar manner, yielding corresponding colouring matters. The production of *Alizarin-cyguines* is also described. These dyestuffs are obtained by treating the "bordeaux" in a sulphuric acid solution with oxidising agents such as manganese dioxide or arsenic acid. All the substances described may be converted into sulphonic acids by suitable treatment with sulphuric acid, and yield products soluble in water, which dye mordanted wool. (See also this Journal, 1891, 536.)

—T. A. L.

Improvements in the Manufacture of Colouring Matters. W. Majert, Berlin, Germany. Eng. Pat. 13,010, August 19, 1890. 6d.

A PROCESS for obtaining sulphonated rhodamines by heating together the sulphophthalic acids with *m* amido phenol and its alkylated derivatives or their ethers with or without a condensing agent.

A colouring matter dyeing the same shade as tetramethylrhodamine is produced by heating together 27 kilos. of acid sulphophthalate of soda, $C_6H_3(CO_2H)_2SO_3Na$, 16.5 kilos. of *m*-dimethylamidophenol, 100 kilos. of 33.3 per cent. hydrochloric acid and 30 kilos. of zinc chloride, in a closed vessel for eight hours to 170°–175° C. The melt is dissolved in water, boiled, and the zinc precipitated with soda. After filtration the colouring matter is precipitated by the addition of acid and salt, and purified by dissolving in water and reprecipitating with salt, after which it is filtered off and dried. It forms a brownish-red colouring matter, easily soluble in water. A similar colouring matter is obtained by heating together 17.4 kilos. of *m*-ethylamidophenol and 26 kilos. of anhydrous sodium sulphophthalate—

The melt after dissolving in water with a little hydrochloric acid is treated in the same way as above.—T. A. L.

Improvements in the Manufacture and Production of Azo Dyes. B. Willeox, London. From the "Farbenfabriken vormals F. Bayer und Co.," Elberfeld, Germany. Eng. Pat. 13,235, August 22, 1890. 6d.

ONE molecular proportion of a tetrazo compound is combined with one molecular proportion of salicylic acid or cresol carboxylic acid and one molecular proportion of α -naphthylamine or α -amido-naphthol-ther. As this compound contains an amido group in the α -naphthylamine residue it can be re-diazotised, and after combination with an amine or phenol, yields valuable fast brown, brown-black, olive green, and black colouring matters, which dye mordanted cotton.

—T. A. L.

The Manufacture and Production of New Sulpho Acids of Dinaphthalene or Amidonaphthol and of Azo Colouring Matters therefrom. B. Willeox, London. From the "Farbenfabriken vormals F. Bayer & Co.," Elberfeld, Germany. Eng. Pat. 13,443, August 26, 1890. 6d.

COLORING matters similar to those described in Eng. Pat. 13,665 of 1889 (this Journal, 1890, 854) and in Eng. Pat. 18,517 of 1889 (this Journal, 1890, 1032) are obtained from a new dihydroxynaphthalene disulphonic acid formed by fusing the α -naphthol trisulphonic acid described in Ger. Pat. No. K. 7567 of 1890. The acid is a disulphonic acid of (1'1') dihydroxynaphthalene and combines with diazobenzene to form a colouring matter which dyes wool and silk red from an acid bath. The specification also describes the preparation of a new amidonaphtholmono-sulphonic acid by fusing 1 kilo. of α -naphthylamine (disulphonic acid with 2.5 kilos. of soda containing 75 per cent. of sodium hydrate, adding 10 per cent. of water, and conducting the fusion at a temperature not exceeding 200° C. The new amidonaphthol sulphonic acid separates out in fine white needles on dissolving the melt in a mineral acid. When combined with tetrazodiphenyl it yields blue-black colouring matters. The dihydroxynaphthalene above described may also be obtained from a new amido-naphthol disulphonic acid, produced by fusing with caustic potash at 180—190° C. The naphthylamine trisulphonic acid is formed by nitrating and reducing the naphthalene trisulphonic acid described in Ger. Pat. 38,281. The new amidonaphthol disulphonic acid on treatment with nitrous acid yields a diazo compound, which on boiling with water gives the dihydroxynaphthalene disulphonic acid described above. The specification contains 13 claims.

—T. A. L.

Improvements in the Manufacture of Colouring Matters. H. H. Lake, London. From A. Leonhardt & Co., Mulheim on the Rhine, Germany. Eng. Pat. 13,565, August 28, 1890. 6d.

BETTER basic colouring matters are obtained by condensing the higher homologues of m -amido-phenols, such as dimethyl- or diethyl m -amido-cresol with p -nitroso derivatives of aromatic amines or with dichloro-amidoquinone. The condensation is performed preferably in a spirit solution, and the colouring matter is precipitated by salt and zinc chloride. —T. A. L.

A Process for the Production of Substituted Benzidines (Diamidodiphenyls) and Colours therefrom. J. Dawson and R. Hirsch, Huddersfield. Eng. Pat. 13,710, September 1, 1890. 6d.

PURPOSES in which the hydrogen atom para. to the hydroxyl group is substituted, are either incapable of combining with diazo compounds or only do so with difficulty, as in the case of di- p -hydroxydiphenyl. If, however, one hydroxyl group be alkylated or if p -hydroxydiphenyl be used in the first instance, the combination can be effected. The

formation of a base from aniline and p -hydroxydiphenyl is described as follows. 10 kilos. of p -hydroxydiphenyl (Eng. Pat. 9080 of 1890, this Journal 1891, 538) are dissolved in 200 litres of water and 4.5 kilos. of caustic soda. When cold a diazobenzene solution is run in prepared from 5.5 kilos. of aniline, 20 kilos. of hydrochloric acid, 100 litres of water and 4.1 kilos. of sodium nitrite. The azo compound which forms is filtered off, pressed, dried and alkylated by heating for one hour to 50° C. with 2.5 kilos. of caustic soda, 80 kilos. of spirit, and 7.5 kilos. of methyl bromide. The alkylated compound is filtered off and mixed with a solution of 20 kilos. of tin dichloride in 40 kilos. of hydrochloric acid. When quite white the mother-liquor containing the tin is filtered off, the salt dissolved in as small a quantity of hot water as possible, and after filtering is precipitated by adding sodium sulphate. In place of aniline, o -toluidine, p -xylydine, α -naphthylamine or o -anisidine may be employed, or p -hydroxyphenyl- o -tolyl or p -hydroxyphenyl- α -naphthyl may be substituted for the p -hydroxydiphenyl. The sulphates of the bases are much more easily soluble in hot water than benzidine sulphate, their hydrochlorides are nearly insoluble in water in presence of an excess of hydrochloric acid. The bases are almost insoluble in boiling water. By employing sulphonic acids of aniline and its homologues in which the para position is unoccupied, sulphonic acids of the new bases will be obtained, which on combination with unsulphonated phenols or amines yield colouring matters soluble in water. The colouring matters from all these bases are prepared generally according to the methods described in Eng. Pat. 4415 of 1884 (this Journal, 1891, 131) and Eng. Pat. 15,296 of 1885 (this Journal, 1886, 595). —T. A. L.

The Manufacture and Production of New Amido-Azo Compounds and Azo Dyes therefrom. J. Y. Johnson, London. From the "Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 14,416, September 12, 1890. (Second Edition). 6d.

THE amidonaphthoxyacetic acid and sulphonic acids described in Eng. Pat. 12,386 of 1890 (see above) are, as already mentioned, capable of combining with diazo compounds to form dyestuffs. These dyestuffs can in turn be diazotised and combined with phenols and amines, their sulphonic and carboxylic acids yielding colouring matters, some of which dye wool directly from an acid bath. In practice it is found best to start from the anhydride of the amidonaphthoxyacetic acid and convert this immediately before use into the acid by boiling with caustic soda. After neutralising with hydrochloric acid a solution of a diazo compound is run in, sodium acetate being added if necessary. The amido-azo body forms and partly separates out, and may be filtered off or diazotised in the same solution and combined with a naphthol or its sulphonic acid. The colouring matters so formed dye shades from green to blue-black according to the various constituents chosen for the several combinations. —T. A. L.

The Manufacture and Production of New Substantive Dyestuffs. J. Y. Johnson, London. From the "Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 14,620, September 16, 1890. (Second Edition). 6d.

IN Eng. Pat. 12,550 of 1890 (see p. 759), the preparation of a new amido acid, diamidophenoxyacetic acid, is described. This body, on diazotisation gives a tetrazo-compound which combines with phenols and amines, their sulphonic and carboxylic acids to form colouring matters, many of which dye cotton from an alkaline bath, giving shades ranging from yellowish-brown through red and violet to bluish-green. These colours, on treating the dyed fibre with copper sulphate, undergo a change given in the table below, and are then fast to light and alkalis to a very high degree.

Dyestuff obtainable by Combination of one Molecular Proportion of the New Tetrazo Compound with	Colour on Cotton from Alkaline Bath.	Colour after Treatment with Copper Sulphate.
1. Two molecular proportions of 1'4 naphthol sulphonic acid.	Purple blue	Green
2. Two molecular proportions of 1'1' benzoylamidonaphthol sulphonic acid.	Green blue	Green
3. Two molecular proportions of 1'1' dihydroxynaphthalene.	Purple blue	Discoloured
4. Two molecular proportions of 2'3' dihydroxynaphthalene.	Blue	Greyish green
5. Two molecular proportions of 2'3' β -naphthylamine- β -sulphonic acid.	Red	Blue
6. Two molecular proportions of β -naphthylamine.	Red	Blue
7. One molecular proportion of salicylic acid and one molecular proportion of chrysoidine.	Yellow brown	Deep dark brown.

Improvements in the Manufacture and Production of Rosaniline Derivatives. B. Wilcox, London. From the "Farbenfabriken vormals F. Bayer & Co.," Elberfeld, Germany. Eng. Pat. 14,621, September 16, 1890. 6d.

LEUCO-BASES of the rosaniline series are obtained by condensing diamidobenzhydrol, its alkylated and certain other derivatives, with aromatic hydrocarbons, phenol, its homologues, nitro-derivatives, sulphonic and carboxylic acids, α - and β -naphthol, the dihydroxynaphthalenes, and amido-naphthols, in presence of concentrated sulphuric acid. The leuco-bases are oxidised in the ordinary manner with lead dioxide. Some examples of the formation of the leuco-bases and dyestuffs are given:—

I. 27 kilos. of tetramethyldiamidobenzhydrol are dissolved in 150 kilos. of sulphuric acid (66° B.), cooled and shaken with 7.8 kilos. of benzene. After the solution has become of a clear brownish colour it is poured into water and the base precipitated by the addition of an alkali.

II. 32.6 kilos. of tetraethyldiamidobenzhydrol are heated with 15 kilos. of benzoic acid and 200 kilos. of concentrated sulphuric acid to 100° C. for two hours. The melt is then poured into ice, made up to 1,000 litres, and the cooled solution oxidised by the addition of 79 kilos. of a 30 per cent. paste of lead dioxide. After filtering, sodium carbonate is added, and the resulting precipitate, after washing, forms a green paste, which dyes wool mordanted with chromium salts green, and is fast to milling.

III. 30 kilos. of dimethyldiethyldiamidobenzhydrol and 14 kilos. of *p*-nitrophenol are mixed, and 200 kilos. of concentrated sulphuric acid added. On stirring, a yellow-brown liquid is obtained which is poured into ice and diluted with water. A yellow nitro-leuco-base of the formula—

is precipitated on the addition of an alkali. It rapidly absorbs oxygen turning yellowish green. The base obtained may be oxidised to a green dye or it may be first reduced and then oxidised or reduced, sulphated, and oxidised, yielding a blue-green acid colouring matter.—T. A. L.

A Process for the Manufacture of Black Colouring Matters. O. Imray, London. From the Society of Chemical Industry in Basle, Basle, Switzerland. Eng. Pat. 15,120, September 24, 1890. 6d.

By combining diazotised α -naphthylamine disulphonic acid with α -naphthylamine an amido-azo-compound is obtained, which can again be diazotised, and this on combination with ethyl- β -naphthylamine yields a colouring matter which dyes wool and silk grey to blue-black. The dyestuff has the formula—

and is fast to soap and light. In place of ethyl- β -naphthylamine the methyl derivative may be employed, and instead of α -naphthylamine disulphonic acid, a sulphonic acid of β -naphthylamine, or the disulphonic acids of aniline, toluidine or xylidine may be used.—T. A. L.

The Manufacture and Production of Blue Colouring Matters or Dyestuffs. B. Wilcox, London. From the "Farbenfabriken vormals F. Bayer & Co.," Elberfeld, Germany. Eng. Pat. 15,345, September 27, 1890. 4d.

THE dyestuff "New blue," produced by the action of nitrosodimethyl- or nitrosodiethyl-aniline on β -naphthol yields, when treated with ammonia in an alcoholic solution and subsequently oxidised, a new colouring matter of a more greenish-blue shade and faster to alkalis than New blue. 25 kilos. of "New blue" are mixed with alcohol to form a thin paste, 7 kilos. of a 20 per cent. alcoholic ammonia solution added, agitated, and allowed to stand until the whole of the ammonia has disappeared. A current of air is then passed through the solution until there is no further increase in the depth of the colour. After dilution with water the alcohol is distilled off, acetic or hydrochloric acid added, and the dyestuff salted out with zinc chloride.

—T. A. L.

The Manufacture of Azo Dyestuffs and of Materials for their Production. S. Pitt, Sutton. From L. Casella and Co., Frankfurt-on-the-Maine, Germany. Eng. Pat. 15,346, September 27, 1890. 6d.

THE substances employed for the production of these colouring matters are the diamido-naphthalene α - and β -disulphonic acids. Both combine with diazo and tetrazo compounds, but only the β -acid is capable of being diazotised. The acids are prepared as follow:—The naphthalene disulphonic acids are converted into dinitro compounds, which on reduction yield the corresponding diamido compounds. 256 kilos. of naphthalene are converted into the disulphonic acid by the action of 1,280 kilos. of sulphuric acid. The melt is cooled down and 350 kilos. of a mixture of nitric and sulphuric acids containing 154 kilos. of HNO_3 run in at 20–30°. This forms a mono-nitro acid. Further 350 kilos. of the mixed acids are run in at 120°–140° C. The melt is then diluted with 4,000 litres of brine (20° B). The dinitro-naphthalene- α -disulphonate of soda separates from the hot liquor whilst the β -salt is precipitated from the filtrate by adding salt and allowing the solution to cool. The separated dinitro compounds are then reduced with iron in the ordinary manner. Instead of separating the dinitro compounds the mixture may be reduced with iron and acetic acid, the iron removed with sodium carbonate and the solution saturated with salt, which precipitates the diamidonaphthalene- β -disulphonate of soda. The α -acid is obtained from the filtered solution by adding 200 kilos. of muriatic acid. The diamido- β -disulphonic acid is almost insoluble in hot and cold water. Its sodium salt dissolves in 21 parts of cold water. The potassium salt is very soluble in cold water, the barium salt is soluble with difficulty. The diamido-naphthalene- α -disulphonic acid is easily soluble in hot water and crystallises in long thin needles. Its sodium salt is soluble in 55 parts of cold water and forms long pointed needles. The potassium salt is less soluble than the β -salt.—T. A. L.

The Manufacture and Production of a New Naphthalene Derivative suitable for Use in the Manufacture of Dye-stuffs. J. Y. Johnson, London. From the "Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 15,803, October 6, 1890. 6d.

WHEN sodium β -naphthol disulphonic acid (B salt) is fused with twice its weight of caustic soda at 240–280 °C a dihydroxynaphthalene monosulphonic acid is obtained. This compound on further fusion at a higher temperature with more caustic soda yields, not as might have been expected, a trihydroxynaphthalene, but a new dihydroxynaphthalene. The same product can also be obtained by treating the sodium salt of the dihydroxynaphthalene monosulphonic acid with dilute sulphuric acid under pressure. The new dihydroxynaphthalene crystallises from water and melts at 160–161 °C. It combines with diazo and tetrazo compounds to form dye-stuffs, and a cold dilute aqueous solution gives an intense blue colour with dilute ferric chloride.—T. A. L.

New Process of Separating Ortho-toluid Sulphonic and Para-toluid Sulphonic Acids. M. Lange, Amer-foort, Holland. Eng. Pat. 15,778, October 6, 1890. 4d.

THE process depends upon the discovery that sulphuric acid containing 66 per cent. of H_2SO_4 dissolves *o*-toluene sulphonic acid, whilst *p*-toluene sulphonic acid remains undissolved in a sulphuric acid of that strength.—T. A. L.

Production of a Yellow Colouring Matter or Dye. J. R. Geigy, Basle, Switzerland. Eng. Pat. 16,666, October 20, 1890. 4d.

By the action of sulphur on tetramethyldiamidobenzhydrol in presence of ammonia and ammonium chloride a colouring matter is obtained which dyes cotton mordanted with tannin a pure yellow. 14.3 kilos. of tetramethyldiamidobenzhydrol or 13.5 kilos. of tetramethyldiamidobenzhydrol and 1.6 kilos. of sulphur are heated to about 140 °C. in a digester fitted with an inlet and outlet pipe. 120 kilos. of salt and 7 kilos. of ammonium chloride are added, the temperature raised to 175 °C. and a current of dry ammonia passed rapidly through the melt for 7–8 hours. The brownish yellow mass formed is treated with a small quantity of cold water. The colouring matter which remains undissolved is dissolved in hot water and precipitated from the filtered solution by the addition of salt.—T. A. L.

The Manufacture and Production of a New Blue Basic Dye-stuff. J. Y. Johnson, London. From the "Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 16,868, October 22, 1890. 6d.

By fusing together nitrosodimethylaniline hydrochloride and *p*-phenylene diamine with or without the addition of benzoic acid, a colouring matter is obtained which dyes cotton mordanted with tannin deep shades of blue, fast to soap and light. The purity of the colour is affected by the temperature employed and the amount of *p*-phenylene diamine used. About 10 kilos. of *p*-phenylene-diamine and 1 kilo. of benzoic acid are heated to 20 °C. in an oil-bath, and 6 kilos. of nitrosodimethylaniline hydrochloride and 3 litres of water are gradually added. The temperature is then slowly raised to 130° and maintained for 3–4 hours. When finished the melt is extracted twice with a hot solution of caustic soda containing 5 kilos. of soda lye (35 per cent. $NaOH$) in 400 litres of water. The colouring matter is thus basified and, after washing with water is dissolved in a 5 per cent. solution of hydrochloric acid and evaporated to dryness. It forms a bluish-black amorphous powder dissolving in water to a violet, in alcohol to a blue, and in sulphuric acid to a bluish-violet solution. The base is insoluble in ether and dissolves in alcohol to a bluish-violet solution.—T. A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

The Chemical Composition of Asbestos. J. T. Donald. Eng. and Mining J. 1891, 741.

WHEN Canadian asbestos was first placed upon the market it had to compete with the Italian mineral, and attempts were made to decry the Canadian article and to prejudice users by the statement that chemical analysis showed the latter to be inferior to the Italian. From different sources samples of the Italian were procured and an analysis was made of the best, the results of which are shown in the first column of the following table. Column 2 shows the composition of a sample from Broughton, which was taken for analysis because of its marked freedom from foreign matter, the Thetford samples first selected for that purpose having been damaged by fire and smoke.

	Italian.	Broughton.	Templeton.
	Per Cent.	Per Cent.	Per Cent.
Silica	40.30	40.57	40.52
Magnesia	43.37	41.50	42.05
Ferrous oxide	0.87	2.81	1.97
Alumina	2.27	0.90	2.10
Water	13.72	13.55	13.46
	100.53	99.33	100.10

These results show that the chemical composition of the Canadian fibre is in no wise inferior to its European rival.

Up to the present time Canadian asbestos may be said to have been obtained exclusively from the Cambrian rocks of Eastern Canada. Of late, however, indications have not been wanting to show that it is possible that the great belt of Laurentian rocks to the north of the St. Lawrence may yet prove to be a rich source of this mineral. It has long been known that seams of short fibre are to be found in those rocks, but it is only within the last year that any attempts have been made to test these veins, and it is gratifying to be able to state that the results of these attempts are promising. Much of the Laurentian serpentine is different from that of Thetford and Black Lake. It is much lighter in colour, and is remarkably free from disseminated chromic and magnetic iron. The contained asbestos is, like the serpentine, of a lighter colour than that from the Cambrian, and in consequence of the absence of iron there is little or no tendency to discolouration from percolating water. The sample of asbestos from Templeton, of which an analysis is given in the above table, was from the Laurentian rocks, and, so far as its composition is concerned, is practically of equal value with the Cambrian asbestos of Broughton.

VI.—DYEING, CALICO, PRINTING, PAPER STAINING, AND BLEACHING.

Ingrain-Black from Diamine-Black. T. Baldensperger. Bull. de la Soc. Ind. de Rouen, 1891, 18, 489.

THE new black is obtained from diamine-black by diazotising and then developing it on the fibre. The fibre is first dyed with diamine-black, of which it takes up from 1½–3 per cent., and is then diazotised at the normal temperature with a solution containing 1 per cent. of sodium nitrite and 1 per cent. of sulphuric acid of 60° B. The development is carried out in the cold, except in the case

of naphthylamine hydrochloride, when a luke-warm bath is required. The resulting colours vary in shade as is shown in the following table. They are all fast to soda and to acid; light reddens them slightly and they are strongly attacked by chlorine:—

Developer.	Resulting Colour.	Loss per Cent. with Soda or Acid.	Loss per Cent. with Acid.
Phenol.....	Dull blue	15	10—15
Resorcinol.....	Blackish	Turns greener.	Unchanged
Naphthol.....	Blue-black	5	Unchanged
β -Naphthol.....	Blue-violet tinge.	5	Unchanged
Schäffer's naphthol sulphonic acid.	Blue-violet tinge.	10—15	5—10
Piria's naphthol sulphonic acid.	Blue-violet tinge, deeper.	10—15	5—10
Naphthol disulphonic acid (R. salt).	Reddish-blue	10—15	Very little
β - β Naphthylamine sulphonic acid.	Dark blue-black.	10	10
1:5 Naphthylamine sulphonic acid.	Dull violet	5	10
Naphthionic acid.....	Prune	5	10
Aniline.....	Violet-blue	10	Slight
α -Naphthylamine.....	Black-blue	Slightly reddish.	Unchanged
β -Naphthylamine.....	Dark shade of diamine black.	5	Unchanged
1:3 Phenylene diamine	Black-brown tinge.	10	Turned more blue.
1:3 Toluylene diamine.	Black-blue tinge.	5—10	Turned more blue.
1:4 Phenylene diamine.	Blue-violet tinge.	10	Slight
Aniline black.....	Turned more blue.	Turned green.
Indigo.....	20	Slight

From this list it is evident that the shades obtained with amido-compounds are darker than those got with the corresponding phenols; also that the diamido and dihydroxy-compounds give darker shades than the corresponding mono-substituted bodies (*p*-phenylene diamine is an exception). The best black is that got with 1:3 toluylene diamine, which is considerably better than that with 1:3 phenylene diamine. These two colours are of practical value as are those obtained with the various phenols, with the two naphthylamines and the prune got with naphthionic acid. The blue produced with β -naphthol is good, and by substituting Diamine-black B or Diamine blue-black E, for the ordinary Diamine black, bluer shades result. These ingrain blacks hardly bear comparison with aniline black, but the colour can be intensified by a second diazotising and development, or by giving the whole a basis of aniline black, for which purpose 2 per cent. of aniline suffices.

—C. A. K.

Application of Chromium Fluoride in Wool Dyeing for Alizarin Cyanine G. and R., and Alizarin Bordeaux.
Färb. Must. Zeit. 27, 1891; J. Soc. Dyers and Colourists, July 1891.

For the production of clear blue shades in dyeing and of lakes, the colouring matters mentioned require at least 4—6 per cent. of potassium chromate, while for other alizarin colouring matters, 3 per cent. of potassium

chromate, with addition of tartar, or sulphuric acid are usually sufficient. The clearest and bluest shades are obtained with Alizarin Bordeaux and Alizarin cyanines, if to the mordanting bath, prepared with chromium fluoride, oxalic acid is added in the proportion of 2 per cent. of the wool or woollen material to be dyed. After the preparatory mordanting, the dyeing is done without the application of acid, or with the addition of 1 per cent. of acetic acid. An application of larger quantities of oxalic acid in the mordanting acts injuriously. The mordanting baths should be preserved, and freshened up for subsequent operations with only one-half or two-thirds of the original amount of chromium fluoride and 2 per cent. of oxalic acid.

It has, moreover, been observed that the application of potassium or sodium bichromate is not to be recommended because in mordanting with them there is fixed on the fibre not only chromium oxide but also chromate of chromium, which latter oxidises the alizarin colouring matters. The shades thus produced are considerably duller. Although this evil may be counteracted by passing the wool, which by the previous mordanting with bichromate of potassium or sodium has assumed a yellow appearance, through a solution of bi-sulphite, and thus changing the yellow chromate of chromium into the green chromium oxide, it has nevertheless been found advantageous to employ chromium salts, which exclusively precipitate chromium oxide on the fibre. *Chromium fluoride* is therefore to be recommended as the best chromium salt.

Although this salt is apparently more expensive than the bichromates of potash or soda, it has, on the other hand, the advantageous property of fixing exclusively chromium oxide on the wool, and of rendering the application of acids, such as oxalic and tartaric acid (tartar and sulphuric acid), unnecessary, but its chief advantage lies in the circumstance that the wool will attract a considerably greater quantity of chromium oxide from a solution of chromium fluoride than from a solution of bichromate of potash or soda containing the same quantity of chromium.

The results of a series of experiments have shown that if, for instance, a quantity of chromium fluoride amounting to 1 per cent. of the weight of the wool be used as mordant, all the chromium oxide is fixed on the fibre, while a quantity of potassium bichromate, with an equal amount of chromium oxide, used for the same purpose, leaves only one-half of the latter on the fibre.

By employing 2 per cent. of chromium fluoride (without an addition of oxalic acid), 78 per cent. of it is fixed on the fibre, and only 13 per cent. of the chromium oxide contained in the chromium fluoride remains unaltered, while with bichromate of potassium about 50 per cent. cannot be fixed. In using 4 per cent. of chromium fluoride only about 30 per cent. remains in the bath, while about 60 per cent. of the chromium oxide present remains in the potassium chromate bath.

These numbers show the necessity of preserving the chromium baths if the chromium salt contained in them is to be exhausted. But while this is easily possible with the chromium fluoride baths, in which the chromium salt remains present as unchanged chromium fluoride, the chromate of potassium bath, after mordanting, contains not only unaltered chromate of potassium, but also chromate of chromium oxide, which, as stated, has quite a different and, in this case, an injurious effect.

While it has, therefore, hitherto been justly inadvisable to preserve the baths which, after the mordanting, still contain about 50 per cent. of chromate of potassium, which were given up as lost, the preservation of the chromium fluoride bath is not only possible, but is to be highly recommended. The chromium fluoride bath preserved for further use may be brought exactly to the original strength of chromium by means of the table below, or by simply adding to such chromium fluoride baths as were prepared with 4 per cent. of chromium, from one-half to two-thirds of the original chromium fluoride—that is, 2—3 per cent.—which will make the bath as effective as it was before.

This advantage of chromium fluoride is further enhanced by the circumstance that while the wool is strongly attacked and weakened by the chromate of chromium, as formed in the chromate of potassium or sodium baths, this is not the

case with chromium fluoride, because the hydrofluoric acid set free in the baths does not act upon animal fibre. In dark colours, which require much chromium, the advantage of the fibre remaining stronger and considerably softer is of eminent importance.

The best recipe for dyeing is the following:—To dye 100 kilos. of wool, 4 kilos. of chromium fluoride and 2 kilos. of oxalic acid are dissolved in a wooden vat, provided with a leaden boiling pipe; the material is brought into the lukewarm solution and boiled for 1½ to 2 hours, exactly as with potassium chromate. The wool is then allowed to cool, rinsed, and dyed finally in a second wooden vat with leaden boiling pipe, without the application of acid, with the requisite quantity of Alizarin-bordeaux or Alizarin-cyanine.

The baths are preserved, and to the subsequent mordanting baths an addition is made of only one-half to one-third of the chromium fluoride originally employed, together with 2 per cent. of oxalic acid.

It is advisable to use wooden vats for the mordanting as well as for the dyeing, with leaden boiling pipes, which can be more easily handled than copper pipes, and are, besides, less expensive.

With these precautions and conditions Alizarin-Bordeaux produces a reddish and Alizarin-cyanine a greenish blue of great clearness and fullness, less expensive than Alizarin blue. The materials dyed in this manner are very fast to milling, and resist air and light as well as all the other alizarin colours.

Generally chromium fluoride will produce considerably better results with all the alizarin colours and Cloth-reds than potassium or sodium chromate.

With a great number of these colouring matters chromium fluoride has the additional advantage of dyeing in a single bath, except in the case of Alizarin-blue, Gallein, Curdlen, &c.

The only inconvenience in dyeing with chromium fluoride in a single bath, though it is avoidable, consists in an unevenness of the colours obtained if the necessary precautions are not strictly observed. If they are taken, good results are obtained.

The dyeing of Alizarin-bordeaux and Alizarin-cyanine with chromium fluoride in a single bath is done as follows:—The dye-bath is cooled down to 37° C., and contains for every 100 kilos. of the material to be dyed, the requisite quantity of colouring matter, 4 to 6 per cent. of chromium fluoride and 2 per cent. of oxalic acid; these are dissolved in water, added and well stirred in the bath, after which the material is put in and worked about during 30 minutes; the temperature is then slowly raised to boiling point, the boiling being kept up for 1½ to 2 hours. The longer the time of boiling, the fuller will be the colour.

All the other alizarin colouring matters are dyed in the same manner with chromium fluoride in a single bath, so that every desirable compound shade may be directly produced in a single bath.

In a series of comparative trials 3 kilos. of worsted yarn were separately mordanted with increasing quantities of chromium fluoride and with potassium chromate dissolved each time in 100 litres of water, and the quantity of chromum remaining in the baths after the mordanting was quantitatively determined. The mordanting was done in the usual manner by boiling the wool for an hour and a half with the solution of chromium salt. With potassium chromate oxalic acid was used, but no acid was employed with the chromium fluoride. To ensure an exact comparison, the proportion of chromium fluoride and potassium chromate was such that equal quantities of chromium oxide came into application. Since chromium fluoride contains 42 per cent. and potassium chromate 51 per cent. of chromium oxide, an application of 4 per cent. of chromium salt to 3 kilos. of wool required 30 grms. of chromium fluoride and 25 grms. of potassium chromate.

The following table shows the quantities of chromium oxide which remain in the bath:—

CHROMIUM FLUORIDE WITHOUT ACID.

The Simultaneous Employment of Vegetable and Coal-Tar Dyes for Producing Fast Colours. V. H. Soxhlet. Chem. Zeit. 15, 844–845.

THE rapid development of the coal-tar dye industry has resulted in the more or less complete displacement of many vegetable colouring substances. For instance, madder and turmeric, which were almost exclusively used a few years ago, are now not employed at all. Of the few vegetable dyeing materials still in use, quercitron, fustic, and logwood must be particularly mentioned. In combination with the so-called "alizarin colours" and other artificial dyes, they are employed for the production of numerous compound shades. For instance, a mixed bath of log-wood and Alizarin yellow dyes woollen materials a splendid black, the material being mordanted in a boiling solution of potassium bichromate and tarrar. A most varied series of brown and yellow shades may be similarly obtained on wool by means of fustic in conjunction with Alizarin red, Alizarin orange, Anthracene brown, &c. All these colours are fast towards light and air, and will bear milling. The newer coal-tar dyes, such as dioxin, gambin, &c., can also be advantageously used together with fustic or logwood. Alizarin red is frequently used to brighten the colours produced by logwood on a potassium bichromate and oxalic acid mordant. If the red be allowed to predominate in the dye-bath, splendid brownish-red shades of considerable fastness are obtained. Logwood and fustic are often employed to finish the blacks produced by aniline colours, chiefly on raw material which cannot be uniformly dyed with aniline colours alone. For this purpose the material is passed straight from the aniline bath into a strong extract of logwood, fresh mordanting not being necessary. Logwood in combination with coal tar dyes is largely used for the production of blue shades on wool and cotton. For instance, logwood and Geigy's Gallamine-blue dye fabrics mordanted with bichromate a bright navy blue of great stability. Certain blue shades on wool may be obtained without separate mordanting, as follows:—a suitable salt, generally ferrous or copper sulphate, is added to the bath, and the precipitated lake is dissolved by means of oxalic acid. Two other aniline dyes, preferably a green and a violet, are then added, and the fabric is dyed in the mixture at a boiling temperature. Various attempts have been made to produce compound colours from vegetable and coal-tar dyes. One of the earliest processes of this character is that of Thomson and Claus of Manchester, by which rather thin alkaline dyewood extracts are mixed with some diazo-compound (diazo-xylene dihydrochloride, diazo-toluene sulphonic acid, diazo-benzene

hydrochloride, diazo-benzene nitrate, diazotoluene hydrochloride, &c.). A more recent process is that of Dahl and Co., of Barmen. A fairly concentrated extract of logwood is mixed with a solution of nitrosodimethyl-aniline hydrochloride, and the new colouring body is then salted out. It is said that by means of this product, cotton fabrics may be dyed a deep black, an iron salt being used as mordant.

PATENTS.

Improvements in Dyeing Textile Fibres. R. Hollday, Huddersfield. Eng. Pat. 1813, February 3, 1890. (Reprinted Specification.) *Ad.*

THE specification of this invention has been amended, prior to the sealing of the patent, by order of the Comptroller of the Patent Office. The invention relates to the dyeing of wool or other textile fibres by mordanting the same with chrome, iron, alumina, copper, or lead, and dyeing with the nitroso- or dinitroso- derivatives of the following dihydroxy-naphthalenes:— $\alpha_1-\alpha_2$, $\alpha_1-\alpha_3$ (Armstrong's), $\beta_1-\beta_2$, $\beta_1-\beta_3$ (Ebert and Merz's), $\alpha_1-\beta_1$, and $\alpha_1-\beta_2$ (Ewer and Pick's), various shades of colour being so obtained.—E. B.

Improvements in Machines for Bleaching, Dyeing, Sizing, and Scouring Yarn in the Hank or Warp, and also for Fabrics. S. Spencer, Whitefield. Eng. Pat. 12,652, August 13, 1890. *8d.*

THE objects of this invention are:—First, simplification of the faller-lifting mechanism described in Eng. Pat. 1954 of 1888; second, the provision of means for keeping the yarn ends straight and preventing the hanks, warps, or cloth under treatment from getting entangled; and third, the production of a machine suitable for dyeing, &c. either hanks, warps, or cloth.

A vat *a* (see Fig. 1) is fitted with a driving-shaft *b*, fallers *c*, and a faller-frame *d*. Two shanks *e* are fixed to

Fig. 1.

IMPROVED MACHINE FOR TREATING YARN, &c.

the ends of the faller-frame and arranged to slide in bearings *f*, fastened to the vat. A strong rail *g*, attached to the shanks by means of brackets *f'*, and tied to the faller-frame by stay-rods *h*, is moved up and down by two crank-studs *i*, fixed on worm-wheels *k*, and mounted on studs *l*, the raising or lowering of the rail thus producing a corresponding movement of the hanks placed on the fallers.

Rotary motion is imparted to the faller-shafts by means of worm-wheel gearing on a small upper shaft, which is driven from the lower shaft *b*, either by friction gearing, in which case the rotation of the fallers ceases on the faller-frame being raised, or by a chain and wheels, when the rotation of the fallers continues after they have been raised.

The faller-frame is provided at each end with arms *d'* which project across the vat and carry longitudinally a number of rods *d''* placed between the hanks *z* for the purpose of separating them from one another. In the lower ends of the hanks metal rollers *c'* are placed to stretch the same. The ends of these metal rollers, when

the faller-frame is lowered, rest on the bevelled sides *d'* of the vat.

When employed for bleaching, &c. warps or cloth, the above-described fallers and metal rods are replaced by rollers *c''* and *c'''* (see Fig. 2), supported by a frame *d''*, *d'''*, *d''''*.

Fig. 2.

IMPROVED MACHINE FOR TREATING YARN, &c.

The warp or fabric *z'* to be dyed, &c. is threaded over the rollers and made endless. It is kept in the necessary stretched condition by the guide and tension pulleys *b'*. The drawing of the warps, &c. through the machine by the rollers *c'*, and not merely by the squeezing-rollers *c''*, prevents excessive tension on the same.—E. B.

Improvements in Printers' Roller Composition. W. J. J. Hawkins and J. H. Stacey, London. Eng. Pat. 13,796, September 2, 1890. *Ad.*

THIS invention is for a composition which has an affinity for printers' ink, and is free from glycerin, which is a principal ingredient in roller compositions as usually made, but which repels the ink. A composition prepared according to the following formula has been found to answer well in practice:—glue or gelatin, 1 lb.; water, 12 oz.; linseed or other suitable oil, 1 lb. 8 oz.; treacle or sugar, from 1 lb. to 1 lb. 8 oz.; calcium chloride or potash, $\frac{3}{4}$ oz.; powdered resin (if required), 2 oz. The glue is first soaked in the water and then melted, and the linseed oil (warmed to a temperature of about 150° F.) is then very gradually added and thoroughly mixed with the melted glue. The sugar or treacle is then added to the mass kept at a suitable temperature, and the calcium chloride then incorporated. If a very tough composition be required the resin (dissolved by heat in a little linseed oil) is to be added. The composition may be made non-absorbent of water by dispensing with the calcium chloride and substituting a similar amount of bismuth carbonate.—B. H.

Improvements in Dyeing, Sizing, and Washing Machines. J. Robertshaw, Manchester. Eng. Pat. 14,372, September 12, 1890. *6d.*

AN arrangement for giving automatically to hanks in process of dyeing, &c., a certain number of turns in one direction followed by an equal number of turns in an opposite direction. This is accomplished by bringing alternately into and out of gear a double clutch *g* (see Fig.) fitted upon the driving shaft *h* of the dyeing machine previously patented by the present inventor (Eng. Pat. 841, 1888).

The spur-wheels *b* are actuated by the chain *c*, which gears into the spur-wheel *d* attached to the end faller. This chain receives its motion from a spur-wheel *e* keyed upon a short shaft, to which is attached a bevelled spur-wheel *b'*, which gears alternately with each of the two bevel-pinions *f*, the latter being thrown alternately into and out of gear by the clutch on the main shaft. The clutch *g* is automatically actuated by the lever *k* pivoted on a short shaft *l*, upon which revolves a band-wheel *m*, driven by the band *m'*

from the wheel m^2 keyed on the short upper shaft. A pin n^1 slides in a long slot n in the band-wheel.

Automatic Revolving Gear.

When the machine is working, the motion of the band-wheel brings the projecting pin n^1 into contact with the side of the lever, which it pushes over along with the clutch, so reversing the motion of the short upper shaft, and consequently that of the fallers. By adjusting the size of the wheels m and m^2 and the length of the slot n , any desired number of revolutions of the wheel m^2 may be made before its motion is reversed.—E. B.

Improvements in and Relating to Apparatus for Printing in Colours. W. P. Thompson, London. From P. Auguste Godchaux, Paris, France. Eng. Pat. 7935, May 8, 1891. 11d.

FIVE groups of printing and pressure cylinders, each supplied with a separate inking system, are arranged so as to be simultaneously actuated by the same gearing. According to the course of the paper through the machine there are printed: two colours on the same side of the sheet; two colours on one side and three on the other; or, one colour on one side and four on the other. The colours may be printed by either typography, lithography, or copper plate, or by two or more of these methods. Details of the mechanism cannot be intelligibly given apart from the drawings which accompany the original specification.—E. B.

Improvements in Machines for Printing in One or More Colours. C. J. Vicomte, Paris, France. Eng. Pat. 10,112, June 13, 1891. 6d.

TWO grippers and tapes or other devices employed in connexion with cylinder paper printing machines, for the purpose of seizing the printed paper on the grippers being opened, are replaced by two chains carrying transverse grippers which carry the sheet of paper and hold the same while it is printed, releasing it only after the impression is complete. An arrangement is also claimed for automatically raising the second and following colour distributing rollers so as to permit the passage underneath of the form from the first or preceding colour, this arrangement effecting a reduction in the length of cylinder lithographic and typographic machines. The mechanism is fully described in the original specification with the aid of drawings.—E. B.

VII.—ACIDS, ALKALIS, AND SALTS.

The Utilisation of Ammonia-Soda Waste. Chem. Zeit. 15, 821—822.

IN 1875 the quantity of seaweed collected on the coast of Jutland was estimated at about 10 million kilos. per annum; the chief sorts are: *Zostera marina*, *Fucus vesiculosus*, *F. serratus*, *Laminaria saccharina* and *L. digitata*. The first two contain 36.66 per cent. and 23.65 per cent. of ash respectively (reckoned on the dry substance). The ash of each has the following composition:—

	<i>Z. marina.</i>	<i>F. vesiculosus.</i>
Potash.....	3.18	2.70
Soda.....	6.57	3.94
Phosphoric acid.....	0.50	0.53
Chlorite.....	6.42	2.61
Sulphuric acid.....	3.14	6.65
Sand and silica.....	9.63	4.08
Undetermined.....	6.72	3.14
	36.66	23.65

On account of the heavy tax on salt, an ammonia-soda works at Aalborg endeavoured to use the waste liquor, containing calcium chloride, over again. This could be done by precipitation with sodium sulphate obtained cheaply as Mirabite from Spain, but the "Pearl hardener" thus produced was at that time difficult to sell. Manurial experiments that were carried out with a view to test the efficacy of various artificial manures on the land in the neighbourhood, proved that the best results per unit of cost were obtained from an English superphosphate containing 7—8 per cent. of water-soluble phosphoric acid and 52—55 per cent. of gypsum, its efficiency with the soil in Jutland being due to the latter constituent. As this manure was relatively dear, it was decided to prepare a similar material at a cheap rate from the waste of the ammonia-soda works. This was accomplished by the following process. The clear solution of calcium chloride—the bye-product of the ammonia-soda process—is treated with a quantity of seaweed ash capable of precipitating the lime as sulphate; the resulting calcium sulphate is filtered off and the clear solution containing potassium, sodium and magnesium chlorides with small quantities of bromides and iodides treated with bleaching powder to precipitate any iron that may be present, filtered under pressure, and sufficient barium chloride added to precipitate any residual sulphate, "Blanc fixe" being obtained as a by-product. The last traces of lime and magnesia are thrown out by soda solution, and the clear liquid precipitated with lead nitrate added in sufficient quantity to remove the bromides and iodides as the corresponding lead salts; the precipitation is complete when lead chloride begins to come down along with them. After settling for some time the clear liquor from several such operations is decomposed with Chili saltpetre, yielding potassium nitrate and sodium chloride, which is then used over again as the raw material of the ammonia-soda process. In the event of it not being desired to prepare nitre as a by-product the liquor containing both potassium and sodium chloride is saturated with ammonia in the ordinary way, then saturated with sodium chloride, and finally treated with carbon dioxide as usual, the free carbon dioxide and the ammonium carbonate being driven out of the liquid by heat at the end of the operation, and the ammonium chloride decomposed with lime in the customary manner. The waste liquor containing calcium, sodium, and potassium chlorides is then treated with seaweed ash as before, and the resulting solution evaporated until it contains about 22 per cent. of potassium chloride, up to which point sodium chloride is precipitated. On cooling, about 12 per cent. of potassium chloride are deposited and

the mother-liquor can be used afresh in the manufacture of ammonia soda.

The calcium sulphate obtained by this series of operations is divided into two parts, one of which is burnt and then both are mixed with a rich superphosphate prepared from apatite or similar imported material, and sulphuric acid, in such proportions that a dry friable product containing 7—8 per cent. of soluble phosphoric acid is obtained.

The seaweed ash can be similarly utilised in conjunction with such materials as Stassfurt salts, provided the magnesia be first precipitated with lime, the last traces being thrown down with soda solution as before. The resulting gypsum, if carefully prepared, can be sold as "Pearl hardener," but in any ease will find a use for fixing ammonia in stable manure or as a raw material for selenitic mortars.

The author suggests combining the Leblanc and ammonia-soda processes by precipitating the waste liquor of the latter with salt cake produced by the former, thus obtaining sodium chloride and calcium sulphate. The first can be carbonated in the usual way, and the calcium sulphate used for the purposes suggested above.—B. B.

Experiments in Mashing with Sodium Sulphite and with Acid Calcium Sulphite. J. Heinzelmann. Zeits. f. Spiritusind. 1891, 14, 95.

See under XVII., page 783.

PATENTS.

Improvement in Apparatus for Drying Salt. E. G. Lawrence, London. From S. Pick, Szczekawa, Austria. Eng. Pat. 4695, March 25, 1890. 8d.

The apparatus consists of a brick chamber heated by steam, whilst a current of hot air passes through the same. It is provided on both ends with compartments, which are separated from the intermediate part of the chamber, and also from the outer air, by means of doors, which may be worked by a hydraulic ram. The salt is introduced on carriers suspended on rails, or by means of any other contrivance, in one end compartment, and during this operation the intermediate doors are closed to prevent an inrush of cold air into the whole of the apparatus. The outer door is then closed and the intermediate one opened, to admit the salt into the chamber, and this is repeated till the chamber is filled with salt-carriers. These are withdrawn on the far end as fast as the salt dries, using the same precautions as before to prevent the cold air from entering the apparatus.—H. A.

Treatment of Impure or Waste Potassium Salts for the Manufacture therefrom of Soda, Potash, Hydrochloric Acid, Magnesia, Calcium Sulphate, and Sulphur or Sulphuric Acid. W. L. Wise, London. From the "Chemische Fabrik Bockau," Magdeburg, Germany. Eng. Pat. 9198, June 13, 1890. 6d.

The Stassfurt waste salts consist of the chlorides and the sulphates of potassium, sodium, and magnesium. It is proposed to work them up by treatment with sulphuric acid, for conversion of the chlorides into sulphates, whereby hydrochloric acid is given off, and may be condensed. The mixed sulphates are dissolved in water and treated with milk of lime; the magnesia is thus precipitated along with gypsum; the separation of the latter is completed in a few days, if the solution be of the proper strength, 20° B. (33° Tw.). The magnesia can be separated owing to its lighter specific gravity from the gypsum by means of washing. The solution of sulphates of soda and potash is now decomposed with barium sulphide (prepared in the usual way from heavy spar); the resulting barium sulphate is available for conversion into more sulphide, whilst the alkaline sulphides are evaporated to say 20° B. (33° Tw.), and treated with strong carbonic acid free from oxygen (as obtained by roasting bicarbonates). Sodium bicarbonate is thereby precipitated, and potassium bicarbonate remains in the solution, from which it is obtained by evaporation. The

sulphuretted hydrogen given off in carbonating the solution of alkaline sulphides is available for the manufacture of sulphur or sulphuric acid.

Other means may be employed for the separation of the magnesia, thus by roasting the mixed sulphates with coal until the mass begins to soften. The wear and tear on the furnace will be small, as the magnesia present prevents ready fusion. The resulting mass is then lixiviated, when the magnesia remains, and the alkaline sulphides are dissolved.—H. A.

Improvements in the Production of Acid Sulphates.

W. B. Giles, Leyton; F. G. A. Roberts, London; A. Boake, London. Eng. Pat. 11,979, July 31, 1890. 4d.

The acid sulphates obtained in the manufacture of hydrochloric, nitric, and acetic acids are capable of combining with much more sulphuric acid, with formation of "pentasulphate of sodium, and which possesses apparently the empirical formula of $\text{Na}_2\text{O}, 5\text{SO}_3 + 3 \text{ aq.}$ " The same compound may be obtained direct from the ordinary chloride, nitrate, or acetate of soda.

The claims are:—1st. The invention and production of the above mentioned new salt, viz., pentasulphate of sodium from ordinary (NaHSO_4) or anhydrous $(\text{Na}_2\text{O}, 2\text{SO}_3)$ bisulphate or less acid sulphates of sodium

"2nd. The conversion of the acid sulphates of sodium obtained as bye-products in the manufacture of nitric, acetic or hydrochloric acids (which at the present time have little or no value) into a new and useful product which is a solid dry material capable of being packed and transported in ordinary packages such as iron drums or kegs"—H. A.

Improvement in Apparatus connected with the Manufacture of Sulphate of Ammonia. R. Dempster and J. Dempster, Manchester. Eng. Pat. 12,661, August 13, 1890. 4d.

For the purpose of conveying the contents of the saturator to the drainer, a lead or copper pump is fixed within the saturator, with a suction tube of a like material extending to the bottom of the same. From this suction tube, and preferably below the pump-barrel, a branch tube extends to the drainers. Both tubes are provided with rubber or lead valves which alternately close or open with each stroke of the piston. With a centrifugal pump, of course the valves will not be required.—H. A.

Improvements in the Method of Obtaining Useful Products from Bleaching Powder Dregs and Lime Mud from Paper Works. T. J. Hutchinson, Manchester. Eng. Pat. 13,504, August 28, 1890. 4d.

See under XIX., page 787.

Improvements in the Treatment of Phosphoric Acid for Facilitating its Storage and Transport. B. E. R. Newlands, London. Eng. Pat. 13,863, September 3, 1890. 6d.

See under XVI., page 781.

Improvements relating to the Production of Soda and Chlorine. T. Raynaud, Moustiers, Belgium. Eng. Pat. 14,483, September 13, 1890. 4d.

Sodium chloride and sulphide of iron are heated in the presence of air with the production of chlorine and a residue of sodium sulphate and peroxide of iron. This residue is mixed with charcoal and furnace, whereby a double sulphide of iron and sodium is formed, from which sodium carbonate is obtained by lixiviation and treatment with carbonic acid, and the sulphide of iron can be used over again.—G. H. B.

Improvement in Preparing and Using Permanganate of Soda. R. Leigh, Bolton. Eng. Pat. 11,858, September 20, 1890. 4d.

Cut of sodium manganate is treated, preferably in a vertical vessel, with a current of moist air or air and steam, whereby "the manganate absorbs air and sufficient moisture for crystallisation," and sodium permanganate is formed. An alternate way of working consists in exposing thin layers of manganate to the atmosphere and occasionally turning them over, thus exposing fresh surfaces to the action of the same.—H. A.

Improvements in the Manufacture of Caustic Soda with the Recovery of Reagents employed for repeated Use. J. Sampson, Liverpool. Eng. Pat. 18,835, November 21, 1890. 6d.

The process comprises a cycle of reactions for the conversion of salt-cake or sodium bisulphate into caustic soda and gypsum, by means of calcium phosphate and hydrochloric acid, which are recovered and used over again. Three alternate methods are described, according to whether sodium sulphate or bisulphate, tri- or bicalcium phosphate are used.

In the first and second method tricalcium phosphate is dissolved in hydrochloric acid of 10 Tw., and the solution decomposed either with salt-cake or with sodium bisulphate. The clear liquor, separated from the calcium sulphate so formed, is boiled down to a pasty consistency whereby weak hydrochloric acid is given off; in subjecting it to a red heat in a muffle furnace, the rest of the hydrochloric acid will be evolved and may be condensed. The molten mass, consisting of sodium phosphate and sodium chloride, is run into water, the solution of the same made up to 60–70 Tw. and allowed to cool, whereupon the less soluble salt will crystallise out. The sodium phosphate is made now into a solution of 26 Tw. and is causticised with lime, sodium hydrate and insoluble calcium phosphate being formed, the latter of which may return to the process.

According to the second alternate method, dicalcium phosphate is used, and in order to regenerate this as such, the causticising operation is divided into two stages, in the first of which the phosphoric acid is kept in excess, and in the second stage the rest of the lime added; the first precipitate consists of dicalcium phosphate, and the second precipitate, containing the excess lime, is available for the succeeding causticising operation.

The gypsum will be found to contain a certain amount of phosphoric acid, and is available as manure, or the phosphoric acid may be recovered by reducing the gypsum with coal into calcium sulphide, which is converted in the usual way into calcium sulphhydrate, and then decanted from the insoluble calcium phosphate.—H. A.

An Improvement in Apparatus for Concentrating Sulphuric Acid. F. G. Webb, Manchester. Eng. Pat. 2343, February 9, 1891. 8d.

A series of glass vessels are placed on slabs, arranged in steps, in a heating chamber; the vessels are enclosed near their upper edges in iron plates or slabs, corresponding to the bottom. In each of these vessels is placed, at an angle, a loose tapered glass tube, reaching from the spout of the next higher vessel to the bottom of the particular vessel where it is provided on its side with an outlet slit. The fire-gases pass first into combustion chambers on one side of the heating chamber, and pass from thence in the space left round the glass vessels. The weak liquor is fed into the tube of the uppermost vessel, and displaces a certain amount of acid, which will overflow into the tube of the next vessel, &c., thus causing an intimate interchange in the liquor to be evaporated. The concentrated acid is delivered from the last vessel of the series.

The claim is:—"For concentrating sulphuric acid, a series of glass vessels placed on steps in a heating chamber, each of these vessels being made with an overflow spout and

having placed in it a glass tube reaching down to its bottom from the spout of the next higher vessel, arranged and operating substantially as herein described."—H. A.

A New Alkaline Magnesium Compound. M. W. Beyliky, C. J. Everett, and C. A. Collins, New York, U.S.A. Eng. Pat. 5519, March 31, 1891. 6d.

The preparation of this compound is effected by making up 100 parts of commercial sodium trisilicate with boiling water into a syrup, and agitating it with 11 parts of a mixture of 3 mol. proportions of magnesium fluosilicate and 1 mol. proportion of hydrated magnesium carbonate, which are suspended in 50 parts of water. The result of the reaction is a compound having the general formula $7(\text{Na}_2\text{O} \cdot 5\text{SiO}_2) \cdot 2(\text{MgO} \cdot \text{SiO}_2)$. This compound is endowed with the properties of the simple alkaline silicates as regards application in the arts, and it further possesses the insolubility of those silicates when once thoroughly dried.—H. A.

Improvements in Furnaces for Burning Sulphur and the like. C. H. Fish, Manchester, U.S.A. Eng. Pat. 7757, May 5, 1891. 8d.

The improved furnace is provided on one end with a feed-door for introducing the sulphur and the requisite air; on the other end, near the outlet for the sulphurous acid fumes, there is a receptacle. The sulphur ashes are gradually pushed forward, and arrive in the receptacle substantially free from sulphur, and may be raked out as often as required.—H. A.

Improvement in Process of Extraction of Carbonic Acid Gas from Bicarbonates. E. Lohmann, Andernach-on-Rhine, Germany. Eng. Pat. 9171, June 1, 1891. 8d.

It is known that bicarbonate solutions are decomposed at a boiling heat into monocarbonates and carbonic acid, and that the remaining solution, after cooling, is capable of absorbing fresh quantities of carbonic acid. But the decomposition has in practice hitherto remained incomplete. The inventor finds that the emission and absorption of carbonic acid takes place to its maximum extent when the bulk of the carbonic acid is driven off by boiling under atmospheric pressure and by finishing off the operation under the combined action of steam and pressure.

The apparatus consists of a "boiler," in which the partly decomposed bicarbonate solution from a previous operation is kept at ebullition under pressure; the monocarbonate solution is then forced through a series of cooling pipes and run down a tower packed with coke, where it meets an upward current of carbonic acid from any source. A bicarbonate or protocarbonate solution is formed, which is pumped into a "boiling apparatus," where it is heated and agitated by the steam and carbonic acid given off in the first boiler. More carbonic acid is given off, and passes along with the steam into a condenser, and from thence into a gas-holder, whilst the condensed water is mixed with the monocarbonate liquor from the "boiling apparatus," in order to maintain a uniform concentration of the solution, which returns to the boiler (see below, also Eng. Pats. 9646 and 10,158 of 1891).—H. A.

Improvements in and relating to a Process for the Treatment of Phosphorites or other Phosphatic Material. C. Glaser, Baltimore, U.S.A. Eng. Pat. 9348, June 2, 1891. 6d.

This invention has for its object the extraction of aluminium phosphate from minerals containing the same. The finely-powdered substance is treated with caustic alkali solution of a suitable strength, whereby all the aluminous portion is dissolved and is separated from the clear solution by treatment with carbonic acid, and the solution of sodium carbonate is re-causticised for use over again by treatment with lime. Or the substance is treated with a boiling solution of

sodium carbonate to dissolve out the aluminium phosphate which is afterwards precipitated from the clear solution on cooling. The precipitated aluminium phosphate may be collected in a filter-press and dried at a low temperature without impairing its suitability for direct employment as a manure.—G. H. B.

Improvements in Process for Production of Carbonic Acid.

E. Luhmann, Andernach-on-Rhine, Germany. Eng. Pat. 9646, June 6, 1891. 6d.

It is proposed to use coke for firing the "boiler" (see above, Eng. Pat. 9171) containing partly decomposed bicarbonate solution and to utilise the combustion gases, after washing and cooling, for the reconversion of the monocarbonate solution into bicarbonate. This is then boiled and decomposed by the steam from the "boiler," whereby the bulk of the carbonic acid is given off and is finally completely decomposed, under pressure, in the "boiler."—H. A.

Improvements in the Production of Carbonic Acid from Bicarbonates of Soda. E. Luhmann, Andernach-on-Rhine, Germany. Eng. Pat. 10,158, June 15, 1891. 8d.

The improvements refer mainly to an absorbing tower for the conversion of monocarbonate liquor into bicarbonate, and further, to the construction of a coke furnace which admits of the production of high-strength carbonic acid.

The absorbing tower is provided with a series of horizontal plates or shelves; the cooled sodium carbonate solution from the "boiler" is introduced on the top in form of a spray, and flowing from shelf to shelf, meets a current of carbonic acid which enters from below.

The coke furnace is built after the fashion of "an upright tray furnace and the rear parts of the grate are formed of pipes, the extremities of which enter the boiler at two different parts." The liquor circulating in these is exposed to the full action of the heat, which causes it to give up rapidly its carbonic acid. These pipes serve also to check the introduction of an excess of air, which would weaken the carbonic acid. The coke should not be kept above a dull red heat, to prevent reduction of the carbonic acid into carbon monoxide and formation of "hydro-sulphurous gases."—H. A.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

On the Density of Pure Kaolins and Fireclays and its relation to Plasticity. H. Hecht. Thonindustrie Zeit. 1891, 15, 293.

THE destruction of fireclay bricks in the ovens of the porcelain industry results not merely from the high temperatures employed, but much more from the basic substances brought over mechanically by the furnace gases, which consequently eat into the bricks much quicker when they contain free silica than when they consist only of aluminium silicate. The author analysed the exposed surface portion and also the inside portion of a brick which had stood the action of the fire during 10 calcinings of 24 hours each, and found in the glazed portion 4.34 per cent. of alkalis and in the unattacked portion only 0.96 per cent. of alkalis. In order to protect the furnace lining as much as possible from the action of the ash-particles, the bricks should be made of basic materials and the fireclay plaster should be of a kind which sets quickly on firing. The presence of free silica loosens the stone, as quartz expands on heating. On the other hand clay contracts on heating, and in a series of experiments on 14 clays, the maximum contraction was 20 per cent. in linear measurement.

The pure plastic clays reached a maximum density at a lower temperature than the pure kaolins, and the latter after repeated calcination in the most intense porcelain fire, showed a porosity of 7 per cent. in volume. The author found that the density of materials consisting of pure clay is a measure of plasticity. The porosity of the 14 clays was determined after heating to the melting point of silver, as the plastic clay was not completely permeable by either petroleum or alcohol. The density varied between 18.40 and 38.86 per cent. by volume.—G. H. B.

The Constitution of "Pink-Colour." L. Petrik. Thonindustrie Zeit. 1891, 15, 101.

It is well known that a pink colour is produced on porcelain by mere traces of a chromium compound. According to Leykauf, the colouring body employed is chromium stannate. The author has found that a pink colouring body may be produced as well by the aid of alumina or a mixture of alumina and magnesia, as by means of tin oxide. For this purpose the precipitated hydroxides obtained from 90.6 grms. of ammonia alum and 24.6 grms. of magnesium sulphate are mixed by grinding with 0.5 gm. of potassium chromate. The mass is burnt twice, being well washed after the first burning. During the second ignition the red colour appears. The alumina colouring body is made by mixing the alumina from 90.6 grms. of alum with 0.5—1.0 gm. of potassium chromate and igniting twice, as before. In presence of a larger amount of chromium, the pink colour is more difficult to obtain; and when the percentage of chromium is very large only a green mass results. An increase in the amount of magnesia favours the formation of the red colour; whilst the substitution of lime, baryta, or strontia for magnesia seems to have a contrary effect. Most likely this is so, because the precipitated alumina is coarser, and because, in all probability, the chromium colour compound only appears pink when very finely divided. The author is of opinion that the pink colours prepared in the manner described above will be more stable towards a reducing flame than those containing tin oxide.—H. T. P.

Blue Sub-Glaze Colour for Porcelain. C. Lauth. Sprechsaal, 1891, 24, 121.

A NUMBER of attempts to prepare a colour resembling Chinese blue have induced the author to study the action of various glazes on cobalt blue. Glazes containing much lime or other alkaline earth impart to the blue a violet tinge, which is most marked with those bases having the least affinity for silicic acid, or which combine with silicic acid only at a high temperature. When zinc oxide is employed the colour assumes a Persian blue shade and loses its transparency. Alkaline glazes affect the beauty of the blue colour more favourably than those containing alkaline earths. Glazes containing much alumina are the most suitable, and the author recommends the following glaze mixtures:—

	I.	II.
	Per Cent.	Per Cent.
Silica.....	75.20	75.00
Alumina.....	12.26	12.24
Alkalis.....	7.99	8.36
Lime.....	5.05	4.32

—H. T. P.

Crackled Porcelain. C. Lauth and Dattaily. Sprechsaal, 1891, 24, 321.

PORCELAIN is described as "crackled" when the glaze is broken up in cracks forming a kind of network. The effect is produced by burning on the glaze at a suitably lower

heat; but if the temperature employed be either too low or too high the glaze is apt to peel off from the surface of the article. The cause of the crackling is in the inequality of the expansion coefficients of the glaze and the backing, and this inequality is best attained by modifying the composition of the glaze. This may be done either by increasing its fusibility by a larger proportion of alkalis or by using more silica or alumina to promote greater infusibility. The latter method is to be preferred, as the backing is thereby attacked to a lesser extent and the glaze has a smaller tendency to peel off. The author has used the following glazes with success on a soft porcelain containing 66 parts of silica, 27 of alumina, and 7 of alkalis, like the soft porcelain of Sevres, requiring a kiln heat of 1,350° C. :—

	Ordinary Glaze.	Crackled Glazes.	
SiO ₂	66.18	79.42	69.92
Al ₂ O ₃	14.55	11.80	18.43
Alkalis	3.55	5.81	11.95
CaO	15.90	2.88	..

—G. H. B.

Composition of a Colouring Matter for Glass. G. Hatten-saur. *Chem. Zeit.* 15, 522.

A substance apparently used for imparting a yellow colour to glass had the following composition :—

Moisture	1.71
Carbon	29.94
Silica	10.05
Ferric oxide and alumina	1.38
Manganese dioxide	37.92
Sodium chloride	13.55
Sulphuric acid	0.22
Magnesia	0.23
Lime, traces of baryta, and loss	1.38

It is probably compounded of 45 parts of graphite, 41 parts of pyrolusite, and 14 parts of common salt.—S. B. A. A.

Properties of Clay pressed Wet and Dry. H. Liedtke. *Deutsche Topf- und Zeigl. Zeit.* 22, 199. (Compare this Journal, 1891, 120.)

The author, from the examination of 25 samples of various kinds of clay, has deduced that not all can be successfully pressed in the air-dried condition. A certain small percentage of water (1–6 per cent.) retained in the air-dried state is necessary in order to obtain satisfactory results. Up to a certain point the time of pressure can be varied inversely as the pressure itself without impairing the quality of the product. Clays which when pressed wet tend to form blisters should not be pressed dry, as this objectionable tendency is enhanced thereby.

The compressional strength of dry pressed ware is greater than that of material wet pressed, while its porosity is less. The latter difference decreases when the goods are burnt at a high temperature. The consumption of fuel is greater in the case of dry-pressed goods on account of the larger amount of raw material they contain. The small quantity of water in dry pressed ware, before firing, takes almost as long to evaporate as the amount of water used with ware made of wet clay, although this is three or four times as much.—H. B.

PATENTS.

Improvements in or connected with the Firing of Pottery. L. H. Jahn, Hanley. Eng. Pat. 13,155, August 21, 1890. 6d.

A GUMMY or adhesive solution (gum tragacanth) is applied to the rims and other parts of cups, basins, &c.; and while the preparation is still wet the rims are placed together and

on the top of the other; the result is that during the firing process the articles will adhere firmly together and remain so during the firing, keeping each other in their correct outline, but after firing such articles can be readily separated. This invention is stated to dispense with the use of the rings usually placed on the wares, and to give better results.

—E. G. C.

Transparent Cloisonné Enamel. C. S. Blount, London, V. Ward, Ayot, St. Lawrence, and A. Fisher, London. Eng. Pat. 7885, May 7, 1891. 4d.

TRANSLUCENT cloisonné enamel or glass is made by fusing between strips of metal placed on a background of metal plaster or other suitable material, which is afterwards removed, leaving the enamel fused together with the metal divisions in one piece, the separation of the background causing the product to be translucent.—H. B.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

Apparatus for Removing Briquettes from their Moulds. W. Michaelis. *Thonind. Zeit.* 15, 337, 338.

A FACTOR in the fluctuations observed in the results of the mechanical tests of cement is the possibility of the test-piece suffering injury by removal from the mould. When the moulds are not made in two parts, this is especially likely to occur. The author has devised a simple apparatus for such cases consisting essentially of a metal arm carrying a vertical sliding rod provided at its lower end with a horizontal metal plate of shape similar to that of the briquette. The briquette is gauged in the ordinary way, and while still plastic covered with a piece of tissue paper, a glass plate laid upon it, turned over a piece of tissue paper laid on the other side, brought under the horizontal plate attached to the vertical rod (its position being determined by metal stops), the plate lowered upon its upper surface and secured in this position by a set screw gripping the vertical rod, and the mould raised by hand, leaving the briquette behind. It can then be removed (the paper being stripped off) and set aside to harden.—H. B.

An Improved Method of Preparing Magnesia Cement. *Thonind. Zeit.* 15, 365. (Compare this Journal, 1891, 111.)

WHEN cement made from a mixture of magnesia and magnesium chloride is cast in moulds, the magnesia sinks more or less to the bottom, and the mixture is no longer of the required composition. To avoid this difficulty strong solutions of magnesium chloride (e.g., 33° B.) have been used in order that their viscosity might be such that this tendency to segregation should be less. But such mixtures are too rich in magnesium chloride to be of the strength proper for a well-made magnesia cement. In a German Patent of December 15, 1889, O. Prinz has described a process for remedying this inconvenience. The process consists in the addition to the cement of certain substances capable of hindering the subsidence of the magnesia. Such are albumen, size, gum, dextrin, starch, agar-agar, as well as inorganic bodies such as gelatinous silica, alumina, and ferric oxide. These materials are added to the solution of magnesium chloride and the magnesia then stirred in; in the case of starch the solution is heated until a thin paste is formed. When silica is used it is produced *in situ* by the addition of a not too concentrated solution of water-glass. Gelatinous metallic hydrates can be introduced in either of two ways: in the first a salt of the metal is added to the solution of magnesium chloride and precipitated by caustic soda, while in the second the magnesia itself on its subsequent intermixture serves as a precipitant.

The objection to the use of metallic hydrates is that their formation involves the production of a foreign salt, which remains in the finished cement, reducing its strength and stability. This difficulty is overcome by substituting for the hydrates already mentioned magnesium hydrate, which is itself gelatinous, and can moreover be produced by heating crystalline magnesium chloride. The alternative plan therefore suggested by these considerations consists in using magnesium chloride containing magnesium hydrate in place of the pure substance.—B. B.

Carbolineum Avenarius. F. Filsinger. Chem. Zeit. 15, 544.

THE author has compared this material, which is used as a preservative for timber (this Journal, 1891, 465), with seven imitations that are on the market, and finds it to differ from them in all essential respects. The following are the properties and characteristics of the genuine substance:—Colour, red-brown; specific gravity at 17° C., 1.128; viscosity at 17° C. (water = 1), 10.0; ash, 0.03 per cent.; flashing point, 131° C.; firing point, 190° C.; begins to distil at 230° C.; distillate below 270° C., 10.6 per cent.; between 270° C. and 300° C., 12.0 per cent.; phenols, trace; deposits no naphthalene. The residue left on distillation is clear, red-brown, and viscous. It will be seen, therefore, that the name carbolineum has no reference to the presence of carbolic acid, and that the other properties that are characteristic of it are its high specific gravity and viscosity, low volatility, and its freedom from naphthalene.—B. B.

Magnesia Cement. A. v. Berkel. Monit. de la Céramique et de la Verrerie, 1891, 22, 31.

FLUORSPAR is digested for some time with sulphuric acid; a solution of kieserite or magnesium sulphate is then added, and as soon as hydrofluoric acid begins to be given off, calcined magnesia is stirred into the mixture. Calcium sulphate and magnesium fluoride are formed, mixed with magnesium sulphate. The cement thus produced sets very hard, and is not in the least affected by water. Articles made of it are pressed and dried by exposure to air, or by heat.—H. T. P.

Cement for Metal. H. Spenlé. Monit. de la Céramique et de la Verrerie, 1891, 22, 41.

THIS well-known cement, which is prepared from zinc oxide and zinc chloride and some other material, such as iron slag, powdered glass, &c., may be caused to set more slowly by adding with the zinc chloride, when it is mixed with the other ingredients, some zinc sulphate and powdered limestone. The adhesive power of the cement (for cementing metals) may be increased by the addition of 2 per cent. of ferrous sulphate.—H. T. P.

Imitation Marble. J. G. Maardt. Monit. de Céramique et de la Verrerie, 1891, 22, 90.

THE author proposes the following method for producing imitation marble:—10 parts of burnt gypsum and 1 part of alum are mixed together with water, calcined and powdered. 22 parts of this material are compounded with 22 parts of talc, 4 of magnesium chloride, 44 of calcined fireclay, and 1 part of potash alum. The mixture is suitable for moulding into ornaments, and can be polished or painted. —G. H. B.

PATENTS.

Improvements in the Manufacture of Plastic Compounds for Building and other Purposes, and in Apparatus therefor. R. G. de Vasson and the Société dite "La Subérine," Paris, France. Eng. Pat. 10,962, July 14, 1890. 8d.

COARSELY powdered cork is reduced in a machine consisting of a chamber closed at the bottom by a revolving disc provided with sectors made of hard granular material, such as emery, pebbles, or filings, the shaft upon which the

disc is keyed also carrying a cross-piece with similar sectors, which is free to slide upon it vertically, working in guides upon the inner surface of the vessel. The ground cork is ejected through an annular passage between the disc and the vessel provided with saw-blades, through which it is forced. The ground cork thus obtained is made into a variety of compositions with such materials as sulphate of lime, sesquioxide of iron and dextrin, or for damp places, oxychloride of zinc or magnesium, or when it is to be used as an insulator, with india-rubber or gutta-percha. Animal or vegetable fibres may be added to give greater coherence, and such substances as ammonium phosphate and sodium tungstate, to render the product incombustible. Mouldings made from this composition may be glazed or varnished with talc powder, stearin, paraffin or resin.—B. B.

Improvements Relating to the Impregnation of Organic Fibrous and Cellular Matter by means of an Electric Current and Apparatus therefor. G. A. Oncken, Chicago, U.S.A. Eng. Pat. 11,065, July 15, 1890. 8d.

THE patent relates to a method of impregnating fibrous matter generally, and wood in particular, with alkaline, acid, antiseptic or other solutions, more rapidly than is possible by the usual process. Wood from which veneers are to be cut is commonly treated previously in water or an alkaline solution for 6—36 hours, a time which can, it is claimed, be reduced to one hour by the adoption of the plan patented. This is carried out by running trucks bearing the wood in logs into a long boiler, pumping in the solution with which it is to be treated, raising the temperature from 75°—90° C. by means of steam pipes, and passing a current of electricity between electrodes placed one at each end of the boiler.—B. B.

Improvements in the Manufacture of Artificial Stone. C. George, Berlin, Germany. Eng. Pat. 12,607, August 12, 1890. 6d.

TEN parts of silicic acid powdered and freed from impurities are mixed with 90 parts of water and 100 of quicklime, all by weight. 100 parts of the product are mixed with 100 parts of sand and 5 parts of magnesia or fluorspar, and the mass moulded as desired. The articles are allowed to dry for 12—24 hours, and subjected to steam pressure under 10 atmospheres pressure for 48—72 hours, after which they are treated with boiling saturated calcium chloride solution, at a pressure of 10 atmospheres, for 6—12 hours. They may then be dried by air or the circulation of steam. Marble, magnesia, magnesium limestone, &c., may be substituted for the sand. The stones thus formed are said to resemble marble, sandstone, granite, &c. closely, to be fireproof, and to resist the action of the weather as well as natural stones.—B. B.

An Improved Decorative Artificial Stone. A. McLean, Lewisham. Eng. Pat. 13,105, August 20, 1890. 4d.

CONCRETE made of Portland cement and sand is formed into slabs or blocks, upon the face of which clips of marble and small pieces of metal, such as "brass spelter" are set, the whole being afterwards pressed and rubbed down in the usual manner to form a decorative surface. For indoor work, Keene's or Parian cement may be preferably substituted for Portland cement.—B. B.

Improvements in or connected with Rotative Furnaces or Kilns for Treating and Recovering Waste Gases from Raw or Partially Raw Materials, used more especially and for Example in the Manufacture of Cement. L. Johnstone, Newcastle-on-Tyne. Eng. Pat. 14,380, September 12, 1890. 8d.

THE process of burning carbonate of lime or other carbonate as in the preparation of cement clinker from slurry in the ordinary way, is conducted in a revolving cylinder pre-

ferably inclined towards the combustion end, and arranged so that a considerable mass of the raw material is at the upper or feeding end and evolving carbon dioxide, so that this waste product may be drawn off in a fairly concentrated condition, a result favoured by the introduction of a regulated quantity of steam at the same part of the cylinder. The gas thus obtained may be drawn off, stored, and used for decomposing tank waste or for similar purpose.

At the combustion end of the cylinder are one or two sets of regulators for heating the incoming gas and air previous to the admixture and ignition. The flame is deflected back from the cylinder in a horse-shoe shape, and the products of combustion are led to the outside of the regenerator tubes. The fan drawing off the carbon dioxide, or a damper in the case of the burning of such materials as iron slag, which do not evolve this gas, regulates the length of travel of the flame in the kiln.—B. B.

A New Alkaline Magnesium Compound. M. W. Beylikgy, C. J. Everett, and C. A. Collins, New York, U.S.A. Eng. Pat. 5519, March 31, 1891. 6d.

See under VII., page 768.

A Composition of Matter consisting in Cascin Cement. C. Wittkowsky, Berlin, Germany. Eng. Pat. 8347, May 15, 1891. 6d.

ONE hundred parts of purified or unpurified albuminous matter, such as bullock's blood, are mixed with 8 parts of an earthy hydroxide, such as slaked lime, and 20–35 parts of water-glass. "Firstly, a deposit arises, which, however, again disappears, and a slimy smearable mass results." Wood coated with this preparation and allowed to dry, can be cemented to another piece of wood similarly treated by subjection of the two pieces with their prepared surfaces in contact to heat and pressure, the cement becoming liquid and then hardening under these conditions. The composition may be used for the formation of blocks of artificial wood made from sawdust and similar finely-divided ligneous material.—B. B.

X.—METALLURGY.

The Basic Siemens-Martin Furnace, with Magnesia Lining. Leo. Dugl. Polyt. J. 280, 260–261.

THE use of the basic-lined open-hearth furnace has latterly become largely extended in Germany owing to the recognition of the great economical advantages it offers. Among these may be mentioned the possibility of working up the poorest scrap and all varieties of iron in which the percentage of sulphur does not exceed a definite amount. In German works, for instance, excellent results have been obtained from charges containing over 60 per cent. of the poor Luxembourg and Lorraine pig, with over 2 per cent. of phosphorus, and it has been found possible to produce a metal thoroughly well adapted for the tin-plate and wire industries from raw materials of the most doubtful description. The soft varieties of basic steel are distinguished for their welding properties, and of late Darby's and Thielens' processes of direct carburisation have rendered it easy to produce the hardest spring steel. As in the acid process, the facility of ascertaining and controlling the condition of the charge at all stages allows of the constant production of a metal of almost any desired composition, but whilst only pure materials can be advantageously treated by the acid process, the basic-lined furnaces are not only available for inferior material, but they work faster,

and are finally the only furnaces in which considerable masses of ore may be worked in with the pig iron with tolerable financial results. The only substances used for forming the basic lining are chrome iron ore, calcined dolomite, and magnesite. The expensiveness and variable quality of chrome iron have led to its gradual disuse, even for the formation of the so-called neutral hearths; of the others, calcined dolomite has the disadvantage that it cannot be stored for any length of time without taking up moisture from the atmosphere and becoming unserviceable; for the same reason, if an open-hearth furnace with dolomitic lining which has been in use for some time be blown out and left cold for a few days, it will be found to be no longer in working order.

Calcined magnesite, on the other hand, is not hygroscopic, and may be stored for any length of time or transported with safety, the slight amount of moisture which is taken up on exposure may be driven off by careful heating, without injury. It is perfectly indifferent to the action of silica, but it must be protected as completely as possible from the action of clay. Its indifference to silica renders it unnecessary to interpose anything between the lining and the siliceous sides of the furnace; in fact it is occasionally used to form an intermediate layer between the sides and a dolomite lining. The corrosive siliceous basic slags have only a transient action on magnesite, and consequently, the repairs necessary after each heat are quickly made, and only small quantities of material are required, whilst in the dolomite hearths about 2 cwt. of dolomite are used in repairs, &c. per ton of produce, and a couple of hours are spent in the work.

The following are some of the most usual dimensions of basic furnaces with magnesite lining:—

The hearth of a 7-ton furnace varies in length from 3·2 to 4·2 metres and 1·9 to 2·3 m. in breadth, with an area of 7 to 8·3 sq. m.; the 8-ton hearth has on the average an area of 9·8 to 10·4 sq. m., the length being about 4·4 m. and the breadth 2·4 m.; an average 10 ton hearth has an area of 9·2 to 12·5 sq. m., with a length of 3·8 to 5·0 m., and a breadth of 2·3 to 2·7 m.; the 12-ton hearth has an area of 14 sq. m., the length being 5·4 m., and the breadth 2·6 m. The best results are obtained from 7-, 8-, 10-, and 12-ton furnaces when the areas of the hearths are 8, 10, 12·5 and 14 sq. m.; the length 4·2, 4·4, 5·0, and 5·4 m., and the breadth 1·9, 2·4, 2·5, and 2·6 m. respectively.

The areas of the cross-sections of the gas and air supply pipes are very variable, there are generally two to four gas pipes and two to five air pipes, and in all the conspicuously successful working furnaces, the cross-sections are equal. Furnaces, on the other hand, in which the sectional areas of the gas and air pipes have a ratio of 22 to 39 or 216 to 385, rarely yielded favourable results.

The air supply pipes are almost invariably placed above the gas ducts, and spread out over the upper part of the furnace the opening being directed towards the hearth. The gas delivery pipes are not disposed symmetrically to the longer axis of the furnace, those lying near the back wall being advanced 15 to 20 cm. towards the centre. The sectional area of the flue into which the waste products of combustion pass is made not to exceed the sum of the sectional areas of the delivery pipes.

The durability of the arch of the furnace is found to increase with its height, and in one of the best-known steel works excellent results have been obtained with dome-shaped arches 2 m. in height. In general, however, the height of the arch above the hearth varies from 1·05 to 1·42 m. The capacity of the heating chambers for air and gas is generally the same; one of the chambers has been made larger than the other in individual cases only. In a well-known Austrian steel works the chambers for the 12-ton furnace had a capacity of 16·4 cbm.

According to experience gained in one large steel works where three 12-ton furnaces had been lined with magnesite alone for many years, a mixture of calcined magnesite and tar being rammed down on the walls, fire-bridges, and hearth; the quantity of magnesite used amounted on the average to 2 per cent. of the weight of steel produced. It generally amounted to 50 to 100 kilos. after each heat, the repairs generally occupying about half an hour.

The hearths formed of magnesite and anhydrous tar have never given rise to any accident and have lasted for 700 and more heats, whilst a new arch of silica bricks was required every 250 to 300 heats, and the surrounding walls had to be renewed every 500 heats. In these furnaces four heats were conveniently worked daily, the duration of each heat, inclusive of repairs, was five hours 10 minutes, of this fully two hours was spent in introducing the charge, which consisted of 18 per cent. of pig iron and 82 per cent. of poor scrap; the average annual production of each furnace is over 11,800 tons. Carburisation of the finished steel with solid carbon has long been practised at these works with good results. When large castings are required it is customary to add ferro-silicon and small quantities of ferro-aluminium to the ladle. In another steel works, where only a 7-ton furnace is used, 960 heats had been worked on the same rammed magnesite hearth up to October 1890. These results are principally due to the fact that the dephosphorisation of the ore is accomplished by the addition of suitable basic materials, and the hearth is accordingly relieved of this duty.

A magnesite hearth may be constructed by either of the methods described below, but in any case the materials must be selected with extreme care, and the work of erection stringently supervised if annoying accidents and breakdowns in the working are to be avoided. The hearth may be formed either by consolidating the magnesite mixed with some binding material either by pressure or by heat, but before the bed of magnesite can be spread on the hearth, a suitable foundation of hard burnt refractory bricks must be prepared; magnesite bricks, though dearer, are preferable for this purpose as they have similar physical properties to the overlying bed. Dinas and silica bricks are disadvantageous on account of their considerable expansion when heated, and subsequent contraction, by which strains are set up in the upper layer, resulting occasionally in rupture. Fireclay bricks are still less serviceable, as clay and magnesite combine at an elevated temperature and form a fusible mass. The materials employed, namely, magnesite bricks, magnesite and the coal-tar used as a cement in the rammed hearths, must be absolutely anhydrous, and are generally used as hot as possible. If any trace of moisture be left it will be converted into steam when the furnace is at work, and as it is prevented from escaping by the compactness of the hearth its tension increases, and may lead to the sealing off and penetration of the hearth. The bricks supporting the hearth must be set with the utmost closeness in mortar mixed with tar, and care must be taken that the smallest hollows on the joints are properly filled up. The tar used for cementing should be frit at a high temperature, but must not swell up on coking, the varieties which become inflated on coking impart a certain porosity and tenderness to the hearth which renders it less able to support the weight of the metal and the mechanical impact of the cold charge. The rammed hearth has the greatest powers of resistance when only 25 per cent. of the calcined magnesite is used in a state of fine powder, the remainder being in grains of 2 to 5 mm. diameter or in particles the size of peas and nuts. The amount of tar required is about 8 to 12 per cent. of the weight of the magnesite. In forming the hearth the mixture is introduced into the furnace in thin layers and uniformly and forcibly pressed down with red-hot stamps until it ceases to show the slightest trace of elasticity. The durability of the hearth largely depends upon this operation being properly conducted, and no pains should be spared to make sure that no portion of the hearth, however small, is loose or elastic. The magnesite lining of the sides of the furnace is strengthened against the attrition of the charge by an additional coating of about 20 cm. from the upper part, and any damage arising from this source during the working may be easily repaired by throwing on the injured part floured and sieved magnesite which has been moderately damped a few hours before use. It is found best to have two large charging doors to the furnace and one small working door in between so as to prevent undue cooling.

The fritted magnesite hearth is far more durable than the rammed hearth. The best results are obtained by mixing finely-powdered calcined magnesite with 5 per cent. of powdered clean basic slag. A magnesite brick foundation is

here also essential, but instead of the tar-mortar the mixture of powdered magnesite and slag is used as the cementing material. The interstices between the bricks must be filled with great care, but this is rendered easy by occasionally tapping the upper layer of bricks, the powder collecting and leaving any vacant places open to observation. On this foundation the mixture is placed in a layer not more than 10 mm. deep, carefully levelled and fritted, a second and a third layer are then similarly fixed; the latter is, however, smoothed with shovels when soft and drawn out towards the tap-hole; the furnace is then ready for use. For the preparation of a fritted hearth the gas from four generators is required for 42—48 hours, but the cost is less than that of a rammed hearth, as less labour and material are expended; its durability is also very much greater, less material is required for repairs, and it is stated that the heats are finished in less time.—S. B. A. A.

On Pure Platinum and some of its Alloys. W. C. Heraeus. Chem. Zeit. Rep. 1891, 15, 170.

By a method which is left undescribed, the author has succeeded in preparing considerable quantities of platinum which does not contain more than 0.01 per cent. of other metals. Platinum of this degree of purity, being too soft for many purposes, was alloyed with varying quantities of pure iridium, and an alloy of pure platinum with 1 to 2 per cent. of pure iridium is recommended for great durability. The pure iridium used in these experiments had a specific gravity of 22.35, and was extremely hard, being equal in this respect to blue-tempered steel. It was completely indifferent towards nearly all chemical reagents, and only fusible in small quantities in the strongest heat of the oxyhydrogen flame. The author also prepared alloys of pure platinum and rhodium. For the purposes of industrial chemistry the author prepares a compound sheet of platinum and gold, in which the contact surfaces of the two metals are alloyed together so as to form a perfect union. Crucibles made in this way can be substituted for the gold crucibles hitherto used in laboratories.

Allotropic Transformations of Metals. H. le Chatelier. Bull. Soc. Chim. 1891, 5, 840—843.

It has been suggested that the variability in physical properties of metals is due to their existence in an infinite number of slightly-different isomeric states. The results of experiments, however, on the specific heats of metals (Compt. Rend. 103, 1122) point to the existence of only a very limited number of allotropic changes. Determinations, again, of the effects of heating metals, show that metals undergo sharply-defined changes at temperatures which vary with the nature of the impurities contained in them (Compt. Rend. 103, 743 and 1135).

The author considers the determination of the electrical conductivity of metals and alloys at various temperatures to be the most satisfactory method of showing the production of allotropic modifications of the same, and finds that molecular transformations take place abruptly in the case of crystalline metals or alloys, and progressively in that of amorphous metals or alloys. A fractured surface of a metal, in a great many cases, shows which of these conditions the metal is in; thus, brass containing 40 per cent. of zinc is readily seen to be crystalline, whereas brass containing 60 per cent. of zinc is amorphous.

The extreme variability in physical properties of metals does not, therefore, depend on the chemical characters alone of the same, but also depends on their internal structure, that is, the form and size of the crystals or grains of metal in juxtaposition, and on the mode of distribution of the impurities.—F. B.

Desulphurising Molten Cast Iron. *Oest. Zeits. für Berg. und Hüttenwesen*, 39, 1891, 206.

WHEN commercial ferrous sulphide (FeS), containing about 36 per cent. of sulphur, is melted together with ferro-manganese, the sulphur separates as a slag in the form of manganese sulphide, leaving the iron free. This reaction is utilised in a process introduced by the Hoerde Steel Works Company in Westphalia, for obtaining pig iron for the basic Bessemer process free from sulphur: experiments having shown that fluid sulphurous metal from the blast furnace might, by the addition of highly heated melted ferro-manganese, be purified to as low as 0.01 per cent. of sulphur. The resulting manganese-sulphide slag contains 20 per cent. and above of sulphur, and about 50 per cent. of manganese; and when subjected to a reducing fusion with lime as a flux, ferro-manganese is recovered and can be applied for desulphurising further quantities of metal. In order to carry out the operation successfully it is necessary to keep the bath liquid for a sufficient time, either by its own or externally applied heat, so that the slag may separate completely. The most convenient apparatus for the purpose is a Bessemer converter, made up with tuyeres in the bottom, and the operation should be repeated several times before pouring, in order to obtain a large volume of slag, which can then be easily removed, and to promote its separation by the stirring action caused by each new addition of metal.

The results of 15 trials at Hoerde, made in August and September 1890, showed that the sulphur in metal from the blast furnace, ranging between 0.27 per cent. and 1.20 per cent., was reduced to between 0.034 per cent. and 0.056 per cent. in the purified metal for the converter, the charges being from 10 to 11 tons each. The sulphur in the finished steel was 0.018 per cent. from a metal originally containing 0.352 per cent., and 0.025 per cent. from that with 1.20 per cent. The effect of spiegel-eisen and ferro-manganese as ordinarily used for recarburising blown metal is somewhat similar, but is less advantageous, as being likely to unduly increase the carbon or manganese on the finished steel.

PATENTS.

Improvements in making Iron of any Quality, Pig Iron, Wrought Iron, Cast Steel, and Rough Steel. A. Dauber, Bochum, Germany. Eng. Pat. 9123, June 12, 1890. 8d.

THE blast furnace is built with horizontal sets of tuyeres at different heights corresponding to the zones of preparation, of reduction, of carbonisation, of melting, and of maturation. No solid fuel is introduced with the burden except when lighting up, and then as the furnace gets into working order this fuel is replaced by gaseous fuel—"carbon in the gaseous state," superheated air and steam and finely powdered coal, all of which are introduced through compound tuyeres in proportions depending upon the zone into which they are injected, and on the condition of the furnace material at that zone. A set of tuyeres is placed round the hearth or "zone of maturation," through which the desired mixture of gases is blown so that the carbon may be reduced to yield any kind of iron or steel from "spiegel-eisen with a high percentage of carbon down to mottled iron containing but traces of carbon"—A. W.

A Hardening Preparation to Harden Iron all through. H. A. van Vught, London. Eng. Pat. 10,949, July 14, 1890. 4d.

Ox hoofs and leather are soaked in French pot-ash, and are then burnt, pulverised and mixed with sea salt and potash. The following proportions are used:—

30 per cent. of hoofs, 30 per cent. of leather, 30 per cent. of sea salt, 10 per cent. of potash.

This product is said to harden iron all through.—H. K. T.

Improvements Relating to the Manufacture of Steel. H. H. Lake, London. From La Société V. Sagramoso and Co., Milan, Italy. Eng. Pat. 11,877, July 29, 1890. 6d.

EXTRA hard steels containing chromium, tungsten, &c. are produced according to this invention from Bessemer or open-hearth metal, by adding to the molten steel in which the necessary degree of decarburisation has been attained, 2 to 3 per cent. of silicon spiegel and 0.05 to 0.15 per cent. of aluminium in the form of a rich alloy. This addition serves to deoxidise the metal and allows the ferro-chromium, tungsten, copper, manganese, or the like which may be added subsequently, to be completely incorporated with the metal. The proportions of ferro-chromium, &c. added are the same as those usual in the manufacture of similar steels in crucibles.—S. B. A. A.

Improvements in the Manufacture of Nickel. L. Mond, Northwich. Eng. Pat. 12,626, August 12, 1890. 6d.

THIS patent is based on the discovery that metallic nickel under certain conditions combines with carbon monoxide to form the gaseous product $\text{Ni}(\text{CO})_4$ from which the metal can be easily separated. The action takes place in the presence of all other bodies, provided the nickel is in a finely-divided metallic state. Oxide of nickel obtained from the ores is reduced to the metallic state by heating it with hydrogen to about 350° C., or with carbon monoxide to 500°. The finely-divided metal so obtained is allowed to cool and at a low temperature—preferably 50° C.—a current of carbon monoxide is passed over it. This gas may be either pure or mixed with some other gases, such as hydrogen and nitrogen, as in producer-gas, but neither oxygen nor the halogens may be present. The carbon monoxide combines with the nickel and carries it off as a gas, which on being passed into tubes or chambers suitably heated, becomes decomposed with the reproduction of metallic nickel and carbon monoxide. The best temperature for this operation is between 180 and 250° C., because below this limit the nickel is not completely deposited and above it the metal becomes contaminated with carbon owing to its power of absorbing this element from carbon monoxide with the formation of carbon dioxide.

The gases can be used over again with advantage, since confining them to the one apparatus obviates any ill effects from the poisonous nature of the "nickel carbon oxide," and moreover any of this compound escaping decomposition in one operation would be saved in the next. The preliminary treatment of the ore is a simple roasting if the nickel is combined with arsenic and sulphur. If it is present as silicate or arsenate, &c. the ore is converted into a speise or matte which is then roasted to oxide.

Other means can be adopted for decomposing the nickel carbon oxide gas, such as mixing with it a hot inert gas or by passing it through hot liquids. It is not necessary that it be decomposed immediately, since it may, by means of a refrigerating apparatus, be condensed to a liquid and bottled. Or it may be absorbed in benzene, petroleum, tar-oils, &c., from which solution, as well as from the condensed liquid, nickel can at any time be separated by heating to the necessary temperature. In this way the metal is obtained free from all impurities, which are left behind, and is even separated from cobalt. After a time the nickel becomes less energetic in its action with carbon monoxide. It is only necessary then to reheat it for a little while to 350° in a current of the gas and to cool it down again, when its energy becomes restored.

The patentee uses an apparatus designed by himself and previously patented (this Journal, 1888, 833). It consists of two cylinders fixed one inside the other with an annular space between them and which turn round together. By projections and a helix the solid substance is made to travel along this annular space from one end of the cylinders to

the other while the gases pass in the opposite direction. A number of such cylinders are connected together in series, so that by the aid of transporting screws and elevators the solid materials as well as the gases can be passed from one to another in succession. In one series the reduction and revivifying is carried on while in another the formation of the metallic gaseous compound takes place. The gases are previously heated to the desired temperature in preference to applying outside heat to the cylinders. The nickel is deposited in tubes suitably heated, of which two sets are employed so as to enable the working to be continuous. The inner surfaces of these tubes are coated with graphite or loam to prevent the metal adhering, or there are introduced thin metallic sheets, bent so as to fit, inside the tubes, on which the nickel is deposited and from which it can be easily removed. "The nickel is thus obtained in coherent bright metallic masses of great purity quite ready for the market."—A. W.

Improvements in or connected with Apparatus for Making Steel. G. Rodger, Sheffield. Eng. Pat. 12,912, August 18, 1890. 6d.

In the open-hearth process the author divides the bed of the furnace into two or more parts by partitions built across it, and provides each part with a separate tap-hole so that separate baths of metal of varying qualities may be prepared in the one furnace.—A. W.

A New Product or Compound for Preventing the Formation of Pores in Molten Metals, and the Manufacture of the same. F. Burger, Hamburg, and R. Mannheimer, Berlin, Germany. Eng. Pat. 13,856, September 3, 1890. 4d.

This product, which is called "anti-porous," consists of a mixture of 100 parts of pure zinc, 2 of lead, and 2 of wax, and is prepared by melting the constituents together. When added to molten metal (gold or silver) it is said to prevent access of air and the consequent formation of pores by forming a layer on the top of the metal. The quantity used is 1 part of the mixture per 100 parts of silver or $\frac{1}{2}$ part per 100 parts of gold. The anti-porous compound is volatilised to such an extent that no injury is done either to the colour or nature of the metal.—H. K. T.

Certain New or Improved Metallic Alloys. F. W. Martino, Sheffield, and F. R. Martino, Birmingham. Eng. Pat. 14,768, September 18, 1890. 6d.

THESE are alloys for the manufacture of boring and cutting tools having a hardness equal to that of tempered steel, with the further advantage of not losing their hardness when heated by friction. The following alloy is suitable for the manufacture of boring tools such as drills, milling-cutters, rhyimers, and the like:—

Pig iron	17.25
Ferro-manganese.....	3.00
Chromium.....	1.50
Tungsten.....	5.25
Aluminium.....	1.25
Nickel.....	0.50
Copper.....	0.75
Bar iron.....	79.50
	100.00

* The following alloy is suitable for the manufacture of nail-cutting blades, cutting blades for machines, cutting-out tools, and the like:—

Pig iron.....	17.25
Ferro-manganese.....	4.50
Chromium.....	2.00
Tungsten.....	7.50
Aluminium.....	2.00
Nickel.....	0.75
Copper.....	1.00
Bar iron (Swedish).....	65.00
	100.00

In making these alloys the pig-iron, ferro-manganese, chromium, and tungsten are melted together in graphite crucibles under stick charcoal and calcined borax, the tungsten and pig iron being preferably melted first. The alloy so produced is then remelted in clay crucibles together with the bar iron; and the nickel, copper, and aluminium are then added. The metal is this time covered with stick charcoal only. The above alloys are cast in sand moulds.—H. K. T.

A Process for the Recovery of the Tin and the Iron from Waste Pieces or Clippings of Tinned Sheet or other Iron or Steel. C. L. C. Berton, Paris, France. Eng. Pat. 15,174, September 25, 1890. 6d.

A CLAIM is here made for treating waste tin-plate with hydrochloric acid and a solution of potassium chlorate or sodium nitrate, under conditions alleged to be particularly favourable to the dissolution of the tin alone. The materials are used in the proportions indicated by the equations—

with the exception that hydrochloric acid is added in slight excess.

The nitrate or chlorate required for dissolving the tin from a ton of scrap is first dissolved in about 110 to 220 gallons of water, the hydrochloric acid added, the solution heated to a temperature between 30° and 50° C., according to the concentration of the liquids, and a first batch of waste introduced. It is essential not to heat the liquids at first above the temperatures given, and not to use an excess of reagents. When the first batch of waste is completely stripped, the residual iron is removed, more waste introduced and treated at a higher temperature. The metallic tin is separated from the liquors either by electrolysis or preferably by fractional precipitation with sodium or calcium carbonate, the oxide of tin being precipitated before any iron, zinc, lead, or copper in solution.

—S. B. A. A.

Improvements in Machinery for Centrifugally Treating Particles of Metallic or Mineral-bearing Substances of different Degrees of Specific Gravity. O. B. Peck, Chicago, U.S.A. Eng. Pat. 673, January 13, 1891. 8d.

THE object of this invention is to provide machinery in which the speed of the revolving vessel receiving the substance to be acted upon may be gradually decreased from a high to a diminished rate of rotation from the commencement to the end of the operation. This is effected by the use of tapered pulleys, spur wheels, and other contrivances acting upon the governor of the engine, the whole being automatically regulated, the result being that the heavier and more valuable particles of the material have been permitted to gradually accumulate in the receiving vessel instead of being thrown off and lost, as would be the case were the vessel rotated at one uniform rate of speed. For details of construction the two drawings accompanying the specification must be consulted. (See also Eng. Pats. 15,343, 15,348, and 15,349 of 1890; this Journal, 1891, 552—553.)—E. S.

Improvements in Mills or Machines for Grinding or Amalgamating Gold, Silver, and other Ores or Hard Substances. G. Fraser, Auckland, New Zealand. Eng. Pat. 2037, February 4, 1891. 8d.

THIS invention consists of an amalgamating pan in which the upper outer edge of the muller carries a removable shoe or ring on which a series of rollers are so mounted that they can revolve and grind against the muller, against one another, and against a wearing ring interposed between the muller and the lower sides of the mill bottom. The mill bottom slants outwards and downwards and at the lowest point communicates with a syphon pipe through which mercury is charged and amalgam withdrawn. Round the central axis above the level of the muller there is an arrangement consisting of an inner vertical frame and an outer frame in

the shape of an inverted cone, between which the overflow water rises and is conducted away. On commencing work the mill is half filled with water, mercury introduced, the miller raised about two inches from the bottom, rotated about 60 to 80 times per minute, and the ore previously crushed so as to pass through a half-inch mesh fed in. The centrifugal force of the revolving miller sets the rollers in motion and gives rise to an efficient grinding action; it further causes a separation of the gangue which passes upwards towards the centre of the mill and into the overflow, from the heavier particles which are driven to the periphery and there amalgamated.—S. B. A. A.

Improved Process and Apparatus for Alloying Metals. W. A. Baldwin, New York, U.S.A. Eng. Pat. 4695, March 16, 1891. *Id.*

This apparatus consists of a furnace of the reverberatory type, on one side of the bed of which is a charging door, and on the other an aperture connected with a hopper. Through the former, molten metal, such as steel, is either run in from a cupola furnace by means of an inclined trough, or is ladled in, while through the latter is introduced the mixture of ores, &c. of the metal to be alloyed with the steel. In producing aluminium steel this mixture consists of clay, salt, and charcoal. The slag is run off through a hole in the side wall and the alloy is tapped by means of another hole under this one leading from near the centre of the furnace bed. These long holes or pipes are provided with doors on the outside of the furnace. There is also built in the roof, immediately over the bed, a small stack or up-take with a damper which is used for the purpose of drawing off the objectionable fumes when necessary.—A. W.

Improvements in the Treatment of Steel. W. B. Middleton, Lancaster, U.S.A. Eng. Pat. 1793, March 17, 1891. *Id.*

This invention consists in impregnating Bessemer or other varieties of steel with silica, silicate of soda, or other silicates. The steel is preferably dipped into a bath of a saturated solution of silicate of soda containing as little soda as possible, heated and rolled or hammered. It is claimed that this treatment not only prevents the steel from deteriorating in quality during the reheating, but also effects a considerable improvement, low-grade Bessemer steel, for example, being converted by the operation into tool steel. The process may be applied with great advantage to scrap or waste steel.—S. B. A. A.

Improvements in the Art of Soldering Aluminium. F. J. Page and H. A. Anderson, Waterbury, U.S.A. Eng. Pat. 8881, May 26, 1891. *Id.*

The inventors claim that surfaces of aluminium may be successfully soldered to each other, and to other metallic surfaces, by using silver chloride as a flux in conjunction with ordinary solder.

The pieces of metal, one or both of which are aluminium, are placed in the relative position required in the joint, finely powdered fused silver chloride spread along the line of junction, and solder melted on with a blowpipe or other device. The joints are thus easily and rapidly obtained, and become hard and perfectly sound on setting, and neither crack, flake, or check.—S. B. A. A.

Improved Apparatus for Use in the Manufacture of Lead Tubes. A. Lockington, Rotherham. From S. K. Morris, Denver, Colorado, U.S.A. Eng. Pat. 9143, July 4, 1891. *Id.*

This is an improvement on the apparatus described in Eng. Pat. 15,904, of 1890. Lead issues from a vessel in which it is melted, through a pipe, the end of which is closed by a plug. This plug does not fit accurately owing to small grooves being filed in the edge of the aperture. The lead issues through these grooves and falls into water. The grooves are easily cleaned by removing the plug.

—H. K. T.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

Determination of Rhodium, Mercury, and Gold by Electrolysis. E. F. Smith. J. Anal. and Appl. Chem. 1891, 5, 200—201.

See under XXIII., page 798.

The Manufacture of "Alumina-Carbon" (Used in the Preparation of Aluminium and Aluminium Chloride). E. Wolfbauer. Chem. Zeit. 1891, 15, 846—847.

THE author recommends the following process for the preparation of the intimate mixture of carbon and alumina used in the manufacture of aluminium and aluminium chloride. Aluminium sulphate is dissolved in one-third of its weight of water, and the solution is mixed at 100° C. with finely-powdered wood charcoal (in quantity equal to one-third of the weight of the sulphate). The mixture is stirred until it forms a thick paste, which is dried at 70° C., and subsequently ignited to a cherry-red heat in a retort, air being excluded. The sulphurous acid which is given off is passed by means of pipes into heaps of moist clay, kaolin, bauxite, or other aluminous material, where it is absorbed. After some weeks or months the aluminium sulphate formed may be extracted by means of water and used for the preparation of further quantities of "alumina-carbon." If the "alumina-carbon" be intended for the manufacture of aluminium by electrical means, it is well to add more carbon and to mould the mixture into rods prior to ignition. The rods possess a considerable electrical resistance, which may be regulated to a nicety by varying the percentage of carbon and the dimensions of the rods.—H. T. P.

PATENTS.

Process for Effecting Electrolytic Deposit with Aluminium. S. Wohle, London. Eng. Pat. 9257, June 14, 1890. *Id.*

Two solutions are prepared. Solution A.—2 kilos. of ammonia alum in 10 kilos. of water. Solution B.—2 kilos. of pearlash, 8 or 10 grms. of ammonium carbonate, 10 kilos. of water. The solutions are mixed and the precipitate which forms washed. The precipitate is then boiled for half an hour with a second solution of alum to which has been added potassium cyanide (4 kilos. of alum, 2 kilos. of potassium cyanide, and 10 kilos. of water). 20 kilos. of water and 2 kilos. of potassium cyanide are next added, and the whole boiled for a quarter of an hour longer. The filtered solution is electrolysed—preferably at 80° to 120° F.—with aluminium anodes. If the deposit be dull the article should be dipped into caustic soda. The bath sometimes works better when allowed to stand some days before filtering, and when some aluminium scrap has been placed in it during the boiling processes.

Improvements in the Manufacture or Production of Zinc from Oxidised Ores of Zinc. T. Parker and A. E. Robinson, Wolverhampton. Eng. Pat. 12,432, August 8, 1890. *Id.*

This is a process for the utilisation of the heat of the electric arc for the reduction of zinc ores. The ore, if a sulphide or carbonate, is first roasted and is then mixed with sufficient carbon in the form of charcoal, coke, pitch, or tar to effect its reduction and give a proper electrical conduction. When pitch or tar is used the mixture is submitted to a preliminary coking before being placed in the electric furnace. The furnace is similar to that described in Eng. Pat. 17,060 of 1889, and consists of a rectangular chamber in which the reduction is effected, the zinc vapours and carbonic oxide passing off by a pipe at the bottom or side of the furnace.—H. K. T.

Improvements in the Manufacture of Sodium and Potassium. H. Y. Castner, London. Eng. Pat. 13,356, August 25, 1890. 8d.

Fused caustic soda or potash at as low a temperature as possible is decomposed by an electric current. When the temperature is high the power of the bath to absorb both the metal and oxygen becomes very great, and practically no decomposition takes place. The material therefore should not be heated to a temperature higher than 20° above its melting point, and at the same time facilities should be given for the rapid separation of the liberated metal from the bath. The apparatus consists of an iron vessel A, mounted in brickwork R, in which the caustic soda is melted by heat supplied by means of the gas burner G. The vessel is provided by one or more base pipes or extensions B, adapted to receive the negative electrode II

APPARATUS FOR THE PRODUCTION OF SODIUM AND POTASSIUM.

which is made of metal, the space K being filled with molten caustic, which becomes set and seals H in position. Above this electrode is suspended a tubular iron receptacle C, provided with a lid N and with a cylindrical piece of iron wire gauze M attached to its lower end. This gauze surrounds H and rests between it and F, the positive electrode. P is an opening for the escape of gas and for the insertion of a thermometer, and S is an asbestos or other insulating medium. The current is supplied through I and L.

The size of the electrodes and their distance apart should be in proportion to the quantity of current. If they be larger than necessary the elements will be subjected to a greater chance of being absorbed by the bath and recombining with a consequent waste of electrical energy. On the other hand, if they are too small the resistance will increase and the bath become overheated just at that part where an elevated temperature is most objectionable. When the decomposition takes place the liberated metal rises and floats on the surface of the caustic in C, whence it is removed by a finely-perforated spoon which allows the caustic to drain through while retaining the metal. Fresh caustic is added to the bath from time to time so that the process may be worked continuously.—A. W.

A New or Improved Solution or Composition for Charging Electric Batteries. A. Clark, Leeds. Eng. Pat. 3799, March 3, 1891. 4d.

For a battery, say of 10 volts, the inventor uses sulphuric acid 1 part to 6 of water, potassium bichromate "powdered to saturation," 10 per cent., ferrous sulphate, 10 per cent., sodium chloride varying from 25 to 50 per cent. and upwards, to which is added chromic acid or copper sulphate, in the proportion of from 5 to 15 per cent. according to strength of current required. By increasing or decreasing the quantity or proportion of the ingredients the power or efficiency of the battery can be regulated.—E. T.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

On the Acidity of various Fats and Lubricants.

R. Kissling. Chem. Zeit. 15, 789.

THE results of determinations of free fatty acid in 52 different commercial samples of oils and fats are given in terms of the equivalent percentage of monohydrated sulphuric acid. 20 samples of pure mineral oils contained traces not exceeding 0.015 per cent. As the quantities in the other samples varied considerably they are given below.

	Free Fatty Acid Calc. as H_2SO_4 .

—G. H. B.

A New Method for the Valuation of Lubricating Oils. J. Lew. Dingl. Polyt. J. 1891, 280, 16—19 and 40—44.

ONE of the most important tests generally employed for determining the lubricating quality of oils is the viscosity test, for which several apparatus (notably that by Engler) have been introduced during the last few years. The author points out that although some viscosimeters give satisfactory results in regard to the relative viscosity of a material, they do not determine the absolute lubricating capacity. For this latter a determination of the internal frictional resistance becomes necessary. The internal friction of the lubricating material itself and the external friction of the liquid with solid bodies are the physical properties which influence the frictional resistance of solid bodies with their lubricants. According to the author, not sufficient attention has hitherto been paid to the fact that the internal and external frictional resistances are different and vary in different oils and at different temperatures. He deduces formulae and describes a method by which these coefficients may be determined and used with great advantage in the valuation of oils for their lubricating properties. The author further gives tables showing the coefficients of internal friction of different oils at ordinary temperatures, and the changes which oils undergo in regard to these factors with varying temperatures. The

method of calculating, the formula, the apparatus for determining the internal friction, &c. cannot be adequately understood without the reproduction of the entire paper.

—K. E. M.

On the Quality of various Lards. C. Engler and G. Rupp. *Zeits. f. angew. Chem.* 1891, 389—391.

See under XXIII., pages 801—803.

Some Experiments on the Changes in Weight which Fatty Oils undergo on Exposure to Air. R. Kissling. *Zeits. f. angew. Chem.* 1891, 395—398.

MULLER, in his book "Die Chemie der austrocknenden Öle," gives the results from all former literature relating to the above subject. Since the publication of this book the following are the most important discoveries on the matter: O. Kirchner's (*Ber.* 21, 101) discovery of some micro-organisms in poppy oil; O. Bach (*Chem. Zeit.* 13, 905—906; see also this Journal, 1889, 990) uses the gumming property of oils for testing machine-lubricating oils, by heating the oil with pure oxygen in a sealed tube in an air-bath for 10 hours and noting the amount of oxygen absorbed. Tatlock (*Zeits. f. angew. Chem.* 1890, 559; this Journal, 1890, 374) finds that some fatty acids, when heated and exposed to air, lose weight, whilst others first gain then lose in weight, and he concludes that volatile oxidation products are formed. Ritsert (*Chem. Zeit.* 14, 1509) finds that rancidity in pure lard is not caused by bacteria, since aerobic and anaerobic bacteria die when inoculated in pure fat, the latter preserving its freshness and not showing acidity when protected from light and air; nor is rancidity the effect of ferments, since sterilised fat which had been heated to 110° C. for several hours became rancid in a closed vessel under the influence of air and light. Rancidity is the result of oxidation under the combined influence of air and light; the presence of water is not necessary. K. Hazura has also published some interesting results on drying oils (*Zeits. f. angew. Chem.* 1888, 312 and 455; this Journal, 1888, 219 and 681; 1890, 807).

With a view to determine definitively whether the absorption of oxygen by drying oils is due to the presence of micro-organisms, the author has studied the oxidation of sterilised boiled linseed oil. The oil, whether sterilised by heating to 120° C. or by treatment with chemicals such as phenol, was found to absorb oxygen from air which had been entirely deprived of carbonic acid and water. The author concludes from this that the absorption of oxygen by drying oils is a purely chemical reaction, in which bacteria or organised ferments have no part.

In order to determine the quantity of oxygen taken up under varying conditions and by different oils, the following experiments were made:—

Equal parts of boiled linseed oil were exposed to the air in different vessels for 10 days:—

Gain in weight	Per Cent.
In a watch glass with 35 sq. cm. oil surface.....	3.10
In a beaker with 35.7 sq. cm. oil surface.....	0.30

The gain in weight would have been quite proportional to the surface area of the oil had the facility for the change of air, being dependent on the shape of the vessels, not been so different.

Crude linseed oil exposed to air and light for 10 days gained 1.95 per cent. in weight.

Crude linseed oil exposed to air and protected from light for 10 days gained 0.87 per cent. in weight.

Tables I., II., and III. show gain (or loss) in weight of different oils, 10 grms. of which, with a surface area of 55 sq. cm., were exposed to the air for 10 and more days at ordinary temperature.

TABLE I.

	Diff. in Weight of 100 parts in 10 Days.	Diff. in Weight of 100 parts in One Day.
1 Olive oil	± 0.0
2 Crude rape oil	+ 0.050
3 Refined rape oil.....	± 0.0
4 Refined neat's foot oil.....	+ 0.065
5 Cotton oil.....	+ 0.515	+ 0.100
6 Crude linseed oil.....	+ 1.130	+ 0.190—0.240
7 Boiled linseed oil	+ 3.490	+ 0.59 —0.14
8 Triolein.....	± 0.0
9 Refined rosin oil	— 0.825

All the oils lost in weight when first exposed to air, with exception of No. 9; however, they gained in weight, after one or more days' exposure. No. 11. table shows how, after a time, the gain in weight becomes proportional to time of exposure until a skin is formed on the surface which interferes with further oxidation.

TABLE II.

No. of Days.	Gain (+) and Loss (—) in Weight of 100 Parts in One Day.		
	Cotton Oil.	Crude Linseed Oil.	Boiled Linseed Oil.
1	— 0.010	— 0.025	— 0.03
2	+ 0.010	— 0.010	+ 0.30
3	+ 0.015	± 0.009	+ 0.40
4	+ 0.025	+ 0.090	+ 0.37

This table further proves the volatility of the oxidation products.—K. E. M.

XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

Filtration of Shellac Solutions. E. Kressel. Chem. Zeit. Rep. 1891, 15, 110.

WHEN commercial shellac is dissolved in alcohol several parts per cent. of insoluble bodies (wax, &c.) are left behind, which must be separated from the solution in order to prepare pure spirit-shellac. To effect this separation the turbid solution is placed in cisterns and a small quantity of carbonate of lead added. After standing 10—14 days the insoluble products are precipitated and the clear shellac solution can be drawn off. The precipitate, if made in sufficiently large quantities, can be employed in the manufacture of oil paints.—C. A. K.

PATENTS.

Improvements in or Relating to Varnishes or other Coatings. J. S. Fairfax, London. From F. Crane, New Jersey, U. S. A. Eng. Pat. 12,684, August 13, 1890. 6d.

"An excellent varnish film especially suited for outdoor work exposed to salt water" is composed as follows:—

Amyl acetate, 50 galls.; spirits of turpentine, 25 galls.; methyl alcohol, 25 galls.; pyroxylin, 37½ lb.; shellac, 37½ lb.
—E. G. C.

An Improved Elastic Cement for Fixing Cycle and other Tyres. W. Sheppard, Chesterfield, and E. Simpson, Mansfield. Eng. Pat. 13,392, August 26, 1890. 4d.

This cement consists of tallow 4 parts, resin 4 parts, and glue 1 part.—E. G. C.

A Process for Bleaching Ground Cork. F. Walton, London. Eng. Pat. 14,829, September 19, 1890. 4d.

THE ground cork used in the manufacture of linoleum, &c., is, according to this invention, bleached as follows:—A bath is prepared of dilute nitric acid (5 to 10 per cent.) and heated to boiling. Whilst boiling, the ground cork is introduced in successive small quantities and the bath well agitated. The cork, on the expulsion of air from it, sinks in the bath, but after a time rises, whereupon a little cold water is added, which causes the cork to sink again. The boiling is then resumed and continued for half an hour, at the end of which time the bath is allowed to cool, the liquid strained off the mass of cork, and the latter washed with water. The washed cork is next treated with bleaching powder and sulphuric acid "in the same manner as for the bleaching of paper pulp," and, after again straining and washing, is pressed and dried.—E. B.

A New or Improved Method of Cleaning, Treating, or Preparing Kauri Gum for the Market. J. C. Firth, Auckland, New Zealand. Eng. Pat. 17,009, October 24, 1890. Amended April 25, 1891. 4d.

THE pieces of Kauri gum are prepared and treated by being submitted, firstly, to the action of bristles of steel or other suitable material, mounted on discs or cylinders, to which a reciprocative, circular, or other motion is imparted, and, secondly, to friction against revolving felt-covered discs.

* The claim is unaffected by the emendation, which consists in adding that the bristles of the abrading tools may be made of "other suitable material" besides steel.—E. G. C.

Improvements in the Preservation of Wood and Iron Imbedded or Buried in the Earth. R. A. Chesbrough, New York, U.S.A. Eng. Pat. 6389, April 14, 1891. 4d.

THIS inventor dips the wood or iron in melted ozokerite, the coating of which is stated to have been proved, by actual tests and experiments, to be absolutely proof against moisture, alkaline and acid solutions, the attacks of insects and worms, &c.—E. G. C.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

PATENTS.

Improvements in the Treatment of Skins and Hides for the Preparation of Leather. H. Belcher, Wantage. Eng. Pat. 14,913, September 22, 1890. 4d.

THIS invention is for preparing hides and skins for tanning by immersing them in dilute sulphuric acid. The strength of the acid solution used will depend on the character of the hides, but the ordinary proportion is $\frac{1}{2}$ lb. of acid to 35 gallons of water. The inventor states that the dilute acid removes the animal matters and the lime used for unhairing which resist the action of the tanning process.

—B. H.

Improvements in Apparatus for Treating or Preparing Leather. A. A. Hunting, Salem, U.S.A. Eng. Pat. 7731, May 5, 1891. 11d.

THIS invention relates to a machine by which partially-tanned leather may be stretched without detriment to its strength, and compressed at the same time to make the fibre denser, so that when "split," a side of leather having a substantially uniform thickness and density is obtained, which "plumps" uniformly during the subsequent completion of the tanning process. The specification is unsuited for abstraction and would be unintelligible without the accompanying drawings.—B. H.

An Improved Embossed Composition Fabric. A. M. Clark, London. From The Fantasie Leather Company, Passaic, U.S.A. Eng. Pat. 2769, June 9, 1891. 6d.

THE improved fabric consists of four thicknesses, the "foundation" being stout, heavy, and coarsely woven cloth. Upon this foundation cloth is spread a thick layer of gum composition. This gum composition may be any well-known gum compound used for making artificial leather or vulcanised india rubber, gutta percha, or similar substance, and is spread in quite a considerable thickness while in a plastic state over the cloth. Upon the surface of the gum composition is spread a cloth which is preferably much finer and more closely woven than the foundation cloth. Upon this second cloth is spread a very thin layer of gum composition which hides the grain of the cloth. The fabric is next embossed by means of a suitable tool and has the appearance of natural leather, is waterproof, and cannot be stretched out of shape.—B. H.

XV.—MANURES, Etc.

Thomas-Slags. Stoklasa. Chem. Zeit. 15, 543—544, and 563—564.

A GREAT many experiments with Thomas-slugs, to ascertain their value as a fertiliser, have been made and recorded, but in the author's opinion they are not of much value, as they have been made with slags of various origin and composition, or different physical structure. The climatic conditions have also greatly varied. To get reliable comparative results, experiments extending over five years with chemically pure preparations have been made by the author.

The chief forms of phosphoric acid (P_2O_5) in concentrated manures are mono-calcium phosphate, free phosphoric acid, di-, tri- and tetra-calcium phosphates. The manuring experiments were carried out according to the modified process of Paul Wagner, and various kinds of soil (humus, clay, lime, sand) were used. Barley was the crop sown. Artificially prepared soils are manured with nitrate of potash, also with the same quantity of phosphoric acid in its various forms. The period of vegetation extended over 55 days. The results given in a table plainly prove that:—

In a humus soil a certain quantity of the phosphoric acid, in the form of a tetra-calcium compound, acts like the same amount of the acid in the mono- or dicalcium phosphate. The more "*Matière noire*" the soil contains, the more valuable the tetra-calcium phosphate becomes.

Experiments made in Bohemia on soils rich in humus have also proved that, in the case of wheat and beet, 1 kilo. of soluble phosphoric acid from a superphosphate has the same effect as 1 kilo. of active phosphoric acid (viz., soluble in citric acid) from a Thomas-slag.

The experiments with Thomas-slugs as a manure for clay soils were made both in March and October. Barley was again used. From the results (communicated in two tables) the author draws the following conclusions:—

(a.) The action of the Thomas-slugs is dependent on the amount of *Matière noire*, which not only retains moisture, but contains both ulmic and humic acids which decompose the tetra-phosphate.

(b.) If the soil contain more than 3 per cent. of *Matière noire* of humus soil, Thomas-slugs may be advantageously used for summer crops, provided they are ploughed in the month of March. If one wishes to get the same results with the slugs as with a superphosphate, it is best to use of its active phosphoric acid, say 75 instead of 50 kilos. per hectare. If the soil be poor in *Matière noire* even 100 kilos. must be used.

(c.) The autumn manuring with Thomas-slugs for winter crops in soils rich in *Matière noire*, is very successful when from 75—100 kilos. of active phosphoric acid are used. The slugs must be either ploughed or harrowed in.

(d.) In lime or sandy soils which contained less than 0.75 per cent. of *Matière noire*, the author found even 100 kilos. of active acid per hectare to be insufficient.

Very interesting results were obtained with slugs which had been treated with sulphuric acid of 1.532 sp. gr. Although the product contained scarcely any soluble phosphoric acid, it still proved superior to the untreated slag, as it raised the produce of beetroots from 40,152 to 50,214 kilos. It was, however, inferior to superphosphate. The author finally suggests that in judging the commercial value of the slugs, the analyst should be only guided by the percentage of active phosphoric acid, viz., the acid soluble in citric acid solution. To carry out the analysis, 2 grms. of the finely-powdered sample are treated with 200 cc. of solution of citric acid (1:2) for two hours, with constant stirring on the water-bath. The filtrate is then made alkaline with excess of ammonia and precipitated with magnesia mixture.—L. de K.

PATENT.

Improvements in Reducing or Disintegrating Apparatus more especially intended for Disintegrating Superphosphates and other Similar Substances. P. U. Askham and W. Wilson, Sheffield. Eng. Pat. 11,474, July 22, 1890. 8d.

See under L., page 749.

XVI.—SUGAR, STARCH, GUM, Etc.

Determination of Ash in the Products of the Sugar Manufacture. E. Donath and G. Hattensaur. Chem. Zeit. 1891, 15, 520.

THE authors have attempted to determine the ash in raw sugar, molasses, &c. directly by mixing the sample with a weighed quantity of powdered pumice, ignited alumina, magnesia, or copper oxide previous to combustion, but without satisfactory results. Better results are obtained by first carbonising the sample, then heating it at the lowest possible temperature in a mixture of air and oxygen and finally in pure oxygen. The ignition is best conducted in a platinum crucible with a small shallow platinum dish with perforated bottom fitting inside, and covered by a perforated lid. The perforated dish serves to distribute the entering gas which would otherwise act more energetically upon the substance in the centre of the dish.—S. B. A. A.

The Manufacture of Rice Starch. J. Berger. Chem. Zeit. 1891, 15, 843—844.

IN the present paper, which forms an addendum to a previous communication (this Journal, 1891, 152—154), the author enters more fully into the improvements he has suggested in the manufacture of rice starch. The great importance of the preliminary softening of the rice with a solution of caustic soda is again pointed out. The precise action of the soda has been misunderstood by most rice starch manufacturers. Many of them have been satisfied to look upon the process as a merely mechanical one; whereas in reality the action is purely chemical. The soda dissolves the albuminous substances which cement the starch-cells together and thus renders them amenable to the after-processes. It is advisable that the solution of the rice-proteins, i.e., the softening process, be carried out as quickly as possible in order to prevent fermentation, which is especially liable to occur in warm weather. The method at present most commonly employed is not at all adapted to serve this end. The rice and soda-lye are allowed to stand in contact for considerable periods of time, the mixture being in some cases occasionally stirred. This stirring is practically useless. In order to get the best results the soda solution should be made to circulate through the rice; and it would need but little alteration of existing plant to effect this desirable object.

There is at present very little chance of some better and cheaper reagent than soda being found. Lime, baryta, and strontia certainly exert a slight solvent action on the albuminoids of rice; but in practice large amounts of these bodies are required to effect a useful softening of the rice; and it is afterwards necessary to remove that portion of the base precipitated as carbonate from the starch by means of an acid. Finally, baryta and strontia are dear, and above all, poisonous. Potash and soda are about equal in their solvent action on the proteins of rice, but ammonia is distinctly less effective. Still, if softening of the rice be the only object sought for, ammonia might possibly be used with advantage. Ammonia dissolves comparatively little protein, but it may be employed in much more concentrated solution than soda without damaging the starch, so that a rapid softening of the rice may be obtained. From the waste

liquor the ammonia may be readily recovered by distillation and used over again. At the same time the proteins held in solution by the ammonia in the waste liquor will be precipitated when the latter is distilled. When soda is used the addition of acid is required to precipitate the albuminoids. In practice, however, the separation of the proteins from the starch must be made the primary consideration; and in this direction soda is much superior to all other substances. Of course, even soda does not dissolve the whole of the albuminoids contained in rice, and it is doubtful whether a reagent to do this will ever be discovered. But it is of interest to know that the greater part of the protein remaining after treatment with soda may be rendered soluble by fermentation. The author is of opinion that a method involving this fact might be of value.—H. T. P.

PATENTS.

Improvements in Saccharate of Lime. W. R. Hutton, Partick. Eng. Pat. 10,449, July 5, 1890. 4d.

THE saccharine body is dissolved in water, an excess of slaked lime added, and the mixture boiled. The proportions recommended are 100 parts by weight of sugar to 15 parts by weight of lime. The claims are:—“1. The manufacture of saccharate of lime, as a liquid or a solid, of fixed chemical composition. 2. The manufacture of saccharate of lime of fixed chemical composition, being a new commercial compound.—A. J. K.

Improvements in the Treatment of Molasses or Syrup for the Purpose of Improving its Flavour. J. Duncan, Selby. Eng. Pat. 11,473, July 22, 1890. 4d.

IN the treatment of molasses or syrup by sulphate of alumina or sulphuric acid, the weaker acids, such as acetic and hydrochloric acids, which have been replaced from their combinations by sulphuric acid, are still left in solution in the syrup, and impart to it a disagreeable taste. They may be removed as follows:—The acid mixture, diluted to 17° B., is evaporated in vacuo or in an open pan to 29 to 30° B., being exposed, in the latter case, during evaporation to a current of air, carbonic acid, or some other gas, which is forced through the syrup by a Korting's or other injector. The vapour given off in this operation contains acetic acid and other volatile impurities. The syrup is now neutralised, filtered and refined in the usual way.—A. J. K.

Improvements in the Treatment of Phosphoric Acid for Facilitating its Storage and Transport. B. E. R. Newlands, London. Eng. Pat. 13,863, September 3, 1890. 6d.

PHOSPHORIC acid, in a more or less pure condition, is now largely employed in the manufacture and refining of sugar, but the forms in which it comes on the market are open to objection. When in solution it is difficult to pack for shipment, and in the form of superphosphate it is mixed with a very large proportion of calcium sulphate, which is very objectionable to add to sugar solutions. The inventor avoids these difficulties by incorporating syrupy phosphoric acid with kieselguhr or infusorial earth, which absorbs more than twice its weight of phosphoric acid of sp. gr. 1.750, with the production of a powder which is perfectly dry to the touch and can be packed in wooden casks or iron drums. As the kieselguhr consists only of silica, its addition to sugar solutions is free from objection.—G. H. B.

Process for the Defecation of Sugar-Cane Juice. H. H. Leigh, London. From W. V. Fry, Lambayeque, Peru. Eng. Pat. 581, January 12, 1891. 11d.

THE juice is defecated with a decoction of the leaves, twigs or other of the smaller growths of the *Eucalyptus*. For this purpose 35 lb. of the eucalyptus growths are boiled with 50 gallons of water for three hours or until the liquor

measures 15° Cartier when hot, or from 9° to 10° when cold. (Degrees Cartier $\times 1.066$ = degrees Baumé.) After straining, the liquor is ready for use, and is used in the proportion of 1½–2 gallons to 500 gallons of sugar juice. After boiling for about 10 or 12 minutes the juice may be filtered by any of the usual methods. The defecant is non-poisonous, and in tropical countries is cheaply and easily obtained.—A. J. K.

XVII.—BREWING, WINES, SPIRITS, Etc.

The Analysis and Judging of Cognac. "Chemiker Verein" in Hamburg. Chem. Zeit. 15, 463.

Before the February meeting of the society, Langfurth read a paper on "The Analysis and Judging of Cognac." The analysis of cognac is simple enough, and approaches to that of wine. It includes the determination of the specific gravity, alcohol, extract, free acid, fusel oil, nature of colouring matter, and cane and invert sugars. But when it is required to form an opinion from the analytical results as to the genuineness of a sample of cognac, a great difficulty is encountered in the fact that the definition of "cognac" is so exceedingly vague. At the present day cognac is no longer the pure distillate from wines grown in the Charente and Charente Inférieure districts, but consists of "raw cognac" distilled from wine, no matter of what origin, mixed with more or less grain-spirit. Raw cognac, i.e., pure wine distillate, costs from 25–30 marks per litre, and is only employed in the preparation of the finer varieties of commercial cognac. The colour of fine cognac is produced by storing the spirit in casks of oak or ash. The cheaper kinds are coloured with caramel or an extract of raisins or plums. Old white wine is also sometimes added, the process termed "adomessage" being used chiefly in order to remove the hard flavour which new cognac sometimes possesses, and which would otherwise only disappear after years of storage. The alcohol percentage of finished cognac steadily diminishes during cask storage, so that old cognacs contain less alcohol than new. In fact, according to Fresenius, a certain well-known French firm sends out cognac containing only 25–30 per cent. of alcohol by weight. It is evident, therefore, that analysis is practically useless for detecting an adulteration of cognac, i.e., excessive dilution with other spirit. As regards artificial cognac prepared from potato spirit, caramel, water, and essence of cognac, the matter is different. Such mixtures may be recognised by testing for certain constituents of genuine cognac, such as aldehyde, butyrol, amyl alcohol, &c. These bodies never occur in artificial cognac. Nevertheless it is quite possible that in course of time the manufacturers of such spirit will learn to add these substances artificially, but for the present the author considers the process of value.

Before the March meeting of the "Chemiker Verein," Wagner described various methods for the estimation of tannins in wines, and states that in his opinion Lowenthal's process is the most suitable. H. T. P.

Influence of Wines on Pepsin Digestion. L. Hugonnet. Bull. Soc. Chim. 1891, 5, 819–855.

The author has investigated the influence on pepsin fermentation of the various substances present in wines. The experiments were made by placing in a flask 5 grms. of fibrine, 0.05 to 0.1 gm. of pepsin, 0.08 to 0.15 gm. of hydrochloric acid, and 50 cc. of the solution or infusion under examination, and keeping at a temperature of 38–40° until a sample on being tested with acid gave no precipitate, a comparative test, in which 50 cc. of distilled water replaced the 50 cc. of the solution, being simultaneously made. The conclusions arrived at are as follows:—

1. All kinds of wine, without exception, hinder the action of the pepsin ferment, those which contain most alcohol, cream of tartar, and colouring matter being most injurious in this respect.

2. The natural colouring matters contained in wine act in conjunction with the alcohol and cream of tartar in hindering or preventing pepsin action.

3. The acidity of natural wines does not in general assist pepsin action.

4. Of the coal-tar dyes employed for artificially colouring wine, Methylene blue, Azollavine, Spirit induline, and, above all, Magenta, oppose the action of the pepsin ferment, as also do the vegetable colouring matters derived from black mallow, elderberries, and "maki."

5. The treatment of wines with plaster of Paris (plâtre) causes the removal of a substance which hinders pepsin digestion *in vitro*, digestion being more rapid in the presence of "vins plâtrés" than in that of wines not so treated.

—E. B.

The Analysis of Top-Yeast in Breweries and in Distilleries by Hansen's Method. A. Jørgensen. Zeit. f. d. ges. Brauw. 1891, 14, 45.

A long series of trials under varying conditions have shown that Hansen's system of testing yeast applies to top yeast as well as to bottom yeast. Also the experience of the author goes to show that one is able to isolate a product characterised by special purity both as regards smell and taste by making a careful and systematic choice of the most suitable top yeast. It is always dangerous to employ mixtures of different top yeasts both in breweries and in distilleries. All top yeast shows a tendency to form more numerous and stronger spores than is the case with cultured bottom yeast, and in all cases there is at least one temperature more favourable to the growth of the crude top yeast than to the corresponding cultured product. Since a considerable number of cultured top-yeasts develop spores on blocks of gypsum at 25° C. in about the same time that the crude products do, a temperature of 15° C. is recommended for their culture, when they develop considerably more slowly than the crude top-yeasts. In cases where there is a difference of only half a day or a few hours in the time of development, a temperature of 12° C. is chosen, when the difference in the time of development becomes more marked, thus allowing the analysis to be made with ease and safety. The spores of the crude top yeast, when young, are clear and homogeneous, with an indistinct wall; those of the cultured top-yeast are less clear and homogeneous, larger, and have, as a rule, a well-defined wall. These differences are chiefly of value when it is not found possible to separate the products by means of the differences of temperature as described above.—C. A. K.

Testing the Keeping Power of Beer. H. van Laer. Station Scientifique de Brasserie, 1890, 72.

The author has examined 15 samples of beer from different countries with a view of testing their keeping qualities. The results arrived at are as follows:—(1.) That the behaviour of the beer at the brewing temperature (25° C.) gives a good indication of its keeping power, due regard being paid to the thickening of the sample. (2.) It is necessary to examine average samples of a cask either by filling several glasses with the beer or by taking the same quantity of liquid from the top, middle, and bottom of the cask. (3.) In taking the samples care must be observed not to allow the liquid to come into contact with the air.—C. A. K.

Method of Detection of Sugared Wine in Natural White Wines. Sochaczewski. L'Union Pharm. 1891, 32, 209.

The method is based on the assumption that wines made from sugar contain larger quantities of colouring and fermentative matters than the natural wines. 20 cc. of the sample are treated with 1.5 to 2 grms. of sodium bicarbonate. The alkaline reaction causes a change of colour, but the solution remains clear in the case of a pure natural wine. With a sugared wine there is no decided change at first, but after several hours the solution becomes cloudy and discoloured, and gradually a very voluminous precipitate forms.—G. H. B.

Experiments in Mashing with Sodium Sulphite and with Acid Calcium Sulphite. G. Heinzlmann. Zeits. f. Spiritusind. 1891, 14, 95.

ACCORDING to Brauer (Chem. Zeit. Rep. 1890, 14, 368), when sodium sulphite is made use of as an antiseptic in mashing, a very marked smell of sulphurous acid is noticeable towards the end of the mash, and the worms of the fermenting vats are in the course of time attacked by the fumes evolved. These observations are not substantiated by the author, who noticed, however, a distinct smell of sulphuretted hydrogen when using sodium sulphite. Parallel experiments made in four distilleries with and without sodium sulphite showed in almost all cases a better fermentation, and consequently better yield, when the antiseptic was used. Acid calcium sulphite behaved similarly to sodium sulphite. The resulting alcohol was free from sulphurous acid and from sulphuretted hydrogen, nor was any smell of the latter noticeable during fermentation. Details of a number of experiments are tabulated. The antiseptic was not found to decrease the acidity of the fermentation in all cases, notably when potatoes were used; the cause of this lies in the large proportion of acid contained in the sweet mash from such products. With mashes of this nature an antiseptic, even hydrofluoric acid, is of little value.—C. A. K.

On the Capacity of Antiseptics to hasten Alcoholic Fermentation. E. Biernacki. Arch. f. Physiol. 1891, 49, 112.

THE results of this research point to the conclusion that all antiseptic substances possess the property, under certain conditions, especially in small quantities, of assisting and hastening the alcoholic fermentation, and this property is the more decided in the stronger antiseptics. The action is more marked in the organic than in the inorganic substances. The antiseptic power of organic bodies seems to be proportional to their richness in carbon, and inversely proportional to the number of hydroxyls (OH) in its constitution. Combination between the substances increases the antiseptic power, and this effect is most marked in combination between organic and inorganic antiseptic substances.—G. H. B.

On the Action of Finings. C. G. Matthews and F. E. Lott. Trans. Inst. Brewing. 1891, 4, 201—216.

FININGS were made with solutions containing equivalent quantities of sulphurous, acetic or tartaric acid; sulphurous acid "cut" the isinglass quickest and the resulting finings kept best; there was little difference between the acetic and tartaric acid finings except that the former kept slightly better. The quantities giving the best finings were found to be 2½ lb. of Russian isinglass cut with 7 galls. of 0.72 per cent. sulphurous acid, and made up to 36 galls.; finings thus made were used in most of the experiments here described.

Lactic acid cuts isinglass better than acetic acid, so when sour beer is used, lactic acidity is most effective.

Isinglass appears to exist in finings in true solution, as when diluted it is not precipitated and will then pass through filtering paper.

When finings are made slightly alkaline, precipitation occurs, the precipitate sometimes rises in the solution, but after a time contracts and sinks, owing to increase of density produced on contraction.

The density of isinglass is about 1.3, rolled samples are slightly denser.

The actual cause of the precipitation of finings in practice appears to be the presence of suspended matter. Cooler grounds, beer grounds, yeast, clay, powdered glass, &c. when suspended in water will each cause the precipitation of finings. The grey drainings of brewers' grains, or a perfectly bright beer, will not take finings, solutions containing bacteria will not "fine" easily, and even if the bacteria are carried down they will most probably work their way out again.

With regard to bodies actually in solution, it was found that alcohol promotes the action of finings, sugar and dextrin have no effect, caramel causes the precipitation of finings and at the same time is itself partly precipitated.

Hop gallo-tannin is only present in beer in minute traces, and its effect on finings may be neglected, except perhaps in the case of "dry hopping." Water containing hop resin in suspension took finings readily. Hop oil diffused through water had no effect on finings, but if other matter be present which will precipitate finings the hop oil will be cleared out if the globules are not very small. Carbonic acid hastens the action of finings. The fining action was assisted by the presence of 0.4 per cent. of acetic acid and retarded by 0.2 per cent. of lactic acid.

Finings added to beer cooled below 40° F. separated in a bulky form and left the beer turbid. If finings have been heated they will not fine beers.

The conditions that are favourable to fining are, dry hopping, presence of suspended matter in beer, especially with hop resin attached to it, alcohol, carbonic acid at low pressure, normal acidity, soluble hop derivatives, and a rising temperature.

The unfavourable conditions are, unusual fineness without brilliancy, flatness, greyness, presence of bacteria, abnormal secondary fermentation, excessive acidity, excessive quantity of suspended yeast.

The authors consider that finings are best made with tartaric acid and a little sulphurous acid subsequently added, or with sulphurous acid alone, and the best isinglass; and that 1 pint containing ½ oz. isinglass should fine a barrel of beer.—A. L. S.

PATENTS.

Improvements in or relating to Distilling Apparatus for Spirits and the like. W. P. Thompson, Caracas, Venezuela. Eng. Pat. 10,436, July 5, 1890. 11d.

THE objects of the apparatus are to economise fuel, to distil two distinct spirits at one and the same time, and to produce a pure spirit of high proof.

Fig. 2 shows an improved furnace setting for the retort, especially useful when the fuel is "cane or wood trash." The cavities A¹ are to retain ashes which may have been carried into the flues A².

Fig. 1 is an elevation, partly in section, of the entire apparatus. A is the retort, a the still head, B the rectifier, D the "vapour still," which is heated by the coil D¹ and fed from the tank E by the pipes E¹ and E². The rectifier communicates by a pipe G with a condenser H, situated in a water-tank F. The condenser is connected with a similar condenser J in a tank J¹. K is a third condenser placed in a tank K¹, which is in communication with the vapour still by a pipe K² which passes through the tank F. Cooling water is supplied to the tank K¹ by a pipe K³, and overflows through the small holes K⁵ into the dish K⁶; thence into the tank J¹, and from this into the tank F, and thence to waste by the pipe F¹.

The vapours issuing from the condensers J and K are conducted by the pipes L and M through the wash heater P to the special condensers N and N¹ and the cooling worms Q¹ and Q²; these are placed in a cold water tank Q. Each condenser consists of an outer vessel n, having within it a similarly shaped vessel n¹ (Fig. 3). The vapour enters at n², passes between the two vessels, through the holes n³ into the interior of the inner vessel, and thence by the outlet n⁴ to the worms Q¹ and Q² (Fig. 1). When the apparatus is to be employed for carrying on two simultaneous distillations, the retort is charged with fermented wash, the rectifier with low wines and the vapour still with spirit which is to be rectified. At the commencement the water tanks J¹ and K¹ should be supplied with some water, but the full supply should not be turned on until the distillation has commenced. When the liquor in the retort commences to boil the vapours are condensed in the worm D¹ or the tube G until the spirit in the vapour still is raised to a sufficiently high temperature, when it commences to boil, and the more volatile vapours pass through the condenser K to the condenser N¹ and worm Q², where they are condensed. The more volatile vapours from the retort then pass through the rectifier B and the condensers H and J to the condenser N

Fig. 1.

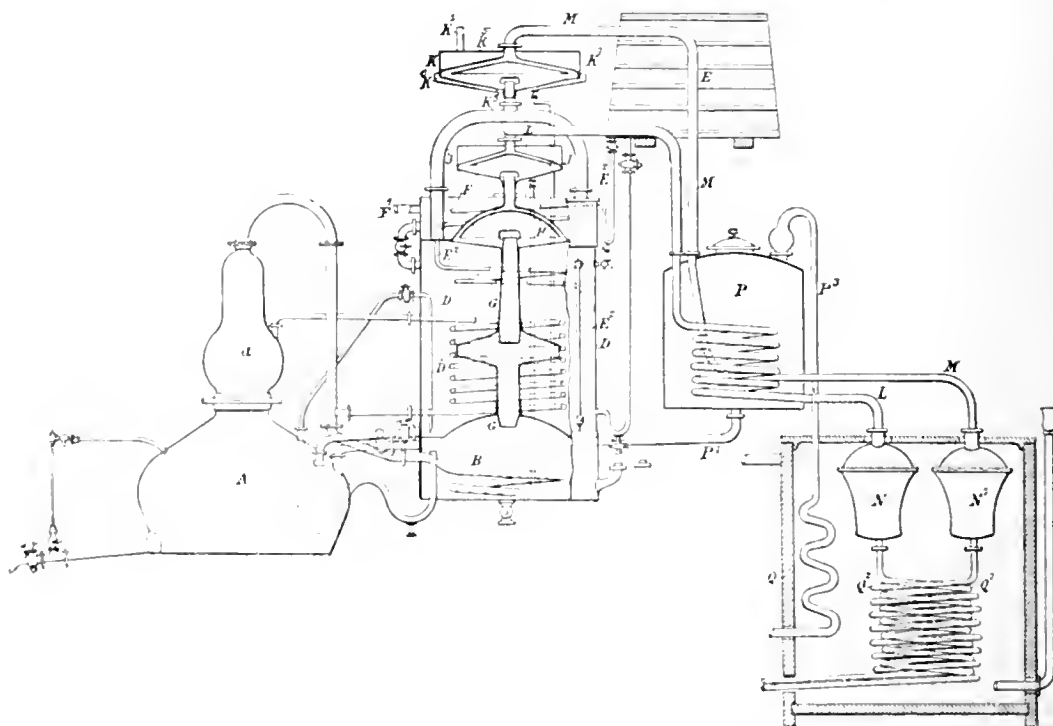

Fig. 2.

Fig. 3.

and coil Q^1 , where they are condensed. To make the operation continuous the retort is kept supplied from the wash heater P by the pipe P^1 , and the vapour still from the tank E by the pipe E^2 . When the vapour still only is employed the retort and rectifier is charged with water.

If the retort be charged with spirit, the strength of the spirit should be reduced to at least 15° Cartier (15° Cartier $\times 1.066 = 15.99$ Baume). The apparatus may also be used to produce one spirit.—A. L. S.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

Honey Testing. E. Dieterich. Helffenbergen Annalen, 1890, 50.

See under XXIII., page 799.

The Present Commercial Importance of Saccharine and the Attitude of the Beetroot Industry with Reference to the Exemption of this Substance from Taxation. F. v. Thumen. Chem. Zeit. 1891, 15, 634–635.

This is a reply to certain remarks made on the above subject by v. Lippmann and Maereker at the meeting of the "Central Agricultural Association" of the province of Saxony, held at Halle on the 19th December 1890, and which were published in the February number of the Journal of the Association.

Fahlberg's saccharine being "300 times as sweet as sugar," it seems at first plausible to suppose that each kilogramme of the former would replace 300 kilos. of the latter on the market. This, however, is not possible since the quantity of sweetening material used by mankind has practically no limit. Even if it were the case, the European sugar industry with its factories which number considerably over 1,000, could

receive but little injury from a product of which the whole world's supply emanates from a single factory. Von Lippmann has asserted that the quantity of saccharine manufactured is equivalent to 240,000 ctrs.; whilst Maereker places it at 600,000 ctrs., and both are of opinion that the German sugar manufacture is injured to this extent. These numbers are quite fallacious and exaggerated, and the fact that the greater portion of the saccharine manufactured in Germany is exported is not taken into account. von Lippmann and Maereker then refer to the noxious effects of saccharine on the human system, citing the investigations of Stutzer and Stift; the experiments of the latter were, however, only made in the laboratory and not on living organisms. They also quote the article published by Worms of Paris. Kornauth has recently made an extended series of experiments with pigs, dogs, and ducks, very large quantities of "saccharinum purum" being administered, and he comes to the conclusion that the substance has neither a noxious effect on the system nor decreases the digestibility of the food in the least; he finds also that the aversion which, according to Stift, animals have towards saccharine is by no means general and only occurs in individual cases, being probably analogous to the aversion which many persons have towards certain foods. Numerous experiments with human beings extending in some cases over several months have led to the same result. The conclusions drawn from the investigations of Leyden, Gerhardt, Rüger, Polatschek, Jessen, Zerner, and Petschek also agree in the main with the last-mentioned.

Saccharine is not a food material, and has never been put forward as such. Maereker objects to the use of a poisonous compound such as phosphorus trichloride in the manufacture of saccharine, this being forbidden by the food laws. His remarks seem however to be directed to the general public, who are unaware that the phosphorus trichloride is subsequently removed.

The statement made by the experts on the commission of the last edition of the German Pharmacopoeia which has been interpreted by those interested in the sugar industry to signify the exclusion of saccharine from the dispensary, is in reality as follows:—"That saccharine is a substance of such wide application that it does not belong to the dispensary."

Lippmann and Maereker's concluding motion that every food material containing saccharine shall be marked as such, the omission being regarded as an infringement of the food laws, does not meet the case, for if saccharine were found to be noxious to health, its sale would then come under the penal laws, and not under the food laws at all.—A. R. L.

(B.)—SANITARY CHEMISTRY.

On the Purification of Sewage. T. König. Chem. Zeit. 15, 541—543.

THE author in a lengthy reply to his critics first of all treats of the action of lime on sewage. It has been argued that lime, without any addition of alum, is capable of purifying the water. Now, it all depends on the nature of the sewage. If it contain substances which are capable of yielding copious insoluble precipitates, for instance, carbonic or phosphoric acid, fatty matters, sugar, dextrin, or salts of heavy metals, &c., an addition of alum may be superfluous.

It has been proposed to determine the amount of lime to be used by a laboratory experiment, but the author does not believe in this, because the same precautions and care can never be taken when operating on the large scale. The question whether lime used in excess is injurious or not is answered by the author in the affirmative. Lime, being a powerful alkali, has a solvent action on nitrogenous organic matter, as has been proved by many hundreds of water analyses. It is true that water treated with excess of lime had for a while lost its bacteria, which fact was taken by bacteriologists as an excellent sign; but no sooner had the alkalinity disappeared than the bacteria at once made their appearance. Another drawback to the use of

excess of lime is the nasty scum which forms on the surface of the water, when exposed to the action of atmospheric carbonic acid.

The author next treats of the purification of sewage by the action of oxygen. The plan recommended is to expose the water as a fine spray to the action of the air. It has been observed that such water has not immediately lost any of its injurious organic matter, but the object of the process is to charge the water with sufficient oxygen, for then bacteria will perform their purifying mission more completely, as the author has observed that in well-drained and aerated soil the micro-organisms perform their functions more completely than in ill-drained and confined soil.

This fact seems to be somewhat ignored by the modern bacteriologists. The bacteria themselves are probably harmless enough, and would never make their appearance if the water were not charged with organic matter. The question is, whether they ought not to be encouraged instead of being destroyed by chemical means. This idea has been, in principle, proposed by Muller and East, who desired to destroy the organic matter by a kind of rapid fermentation. This ingenious plan would, however, require a great number of very large reservoirs, which, in most places, cannot very well be fitted up.—L. de K.

On the Purification of Sewage. H. Schreib. Chem. Zeit. 15, 669—670.

THE author objects to some statements made by König (see preceding abstract), and, having experimented on sewages of widely different origin, concludes that excess of lime diminishes the amount of soluble organic matter. He also holds that experiments may be safely made on the small scale, although as a rule a smaller amount in proportion of the purifying agent need be added when performing on the large scale.

The author, who has witnessed an experiment with König's aerating process (see preceding abstract), had no reason to be particularly pleased with it. In the town of Praeg, chimney gas is used with good success for the purification of the sewage. From this it would seem that abundant supply of oxygen is not so necessary after all.—L. de K.

The Purification of Rivers. O. Loew. Arch. f. Hygiene, 1891, 12, 261.

TO the various means which contribute to the natural purification of rivers, the growth of algae should be added, for these plants are capable of assimilating many substances which are the products of decomposing organic matter. Indol, skatol, phenylpropionic acid, paracresol, phenol, and other aromatic products, together with amido-fatty acids, the pure fatty acids and ammonia, carbonic acid, sulphuretted hydrogen, and methyl-mercaptan are instances of bodies which can afford nourishment to plants of the mushroom tribe, and they may also be taken as affording support to algae, whose assimilating powers are shown to be similar to mushrooms in the case of glycocine, leucine, asparaginic acid, creatine, and betaine.—G. H. B.

(C.)—DISINFECTANTS.

The Disinfecting and Antiseptic Action of Guaiacol. P. Marfori. Annal. di Chimica, 1891, 13, 3.

A LARGE number of experiments go to show that the antiseptic and disinfecting powers of guaiacol are greater than those of many other commonly employed aromatic substances. A 2 per cent. solution of guaiacol is as powerful as a 5 per cent. phenol solution in the case of the mildew bacillus; a 0.5—1.0 per cent. guaiacol solution destroys the tubercle bacillus in 2 hours, whilst a 0.1—0.2 per cent. solution only produces local infection when injected into rabbits. Other bacteria are killed by a 4—5 per cent. solution in 20—30 minutes.—C. A. K.

XIX.—PAPER, PASTEBOARD, Etc.

Soda Wood Pulp. Papier Zeit.; through Chem. Trade J. 9, 107.

The results were obtained by E. Hennefeld in a Swedish pulp works. The principal kinds of timber used correspond to the *Pinus Sylvestris* and *Pinus Abies excelsa*. Trees having a diameter of about 6 inches are now being cut down. The Kiefer (*Pinus Sylvestris*) when felled, is sorted into three different sizes, viz., 15–25 cm., 25–35 cm., and 35 cm. diameter and over. After barking these poles, they are cut up into pieces 12 mm. × 12 mm. × 4 mm. thick, and in this condition used for pulp boiling.

The pulp boilers are capable of holding 8½ cbm. of chopped and cleaned wood, i.e., 245 cb. ft. of piled logs, and to this 6,000 litres of caustic soda-lye containing caustic soda equivalent to 75 kilos. of NaO per cbm. of wood. The pulp boilers revolve, and their contents are heated by direct steam. The pressure employed is 125 lb. above that of the atmosphere, and the length of time the pressure is applied varies with the age and variety of the wood.

Thus for timber of 35 cm. diameter and above, the pressure is maintained for 2 hours. Timber of 35 to 25 cm. diameter, the pressure is maintained for 1½ hours. Timber of 25 to 15 cm. diameter the pressure is maintained for 1 hour.

This done, the steam pressure in the pulp boiler is blown off, and the latter emptied. Each boiler full of wood yields 1,240 kilos. (27½ cwt.) of air-dried pulp or 145.9 kilos. per cbm. of wood (35.28 cb. ft.).

From these figures, according to the Chemical Trade Journal, the following numbers may be deduced:—

60 per cent. caustic required per ton of pulp, 14.75 cwt.
Air-dried pulp per boiler, 24½ cwt.
Cubic feet of wood per ton of pulp, 245.

The Constitution of the Ligno-celluloses. C. F. Cross and E. J. Bevan. Chem. News, 64, 1891, 63.

1.—Recent Investigations of Soluble Products of Wood Boiling (Bisulphate Cellulose Process).

THROUGH the kindness of Prof. Tollens, the authors received a copy of the "Inaugural Dissertation" (Göttingen, 1891), of J. B. Lindsey, embodying the results of an extended investigation of the products of the now widely-known "bisulphate" process of treating wood for converting it into a paper-maker's pulp (cellulose). The object of the latter, working under the guidance of Tollens, was to throw light on the constitution of the substance of fir-wood. The main subject of his inquiry was the constitution of the lignone, or non-cellulose constituent of the wood substance (ligno-cellulose).

This was converted by the process of digestion (at 108° C. Mitscherlich process) into a soluble derivative, probably, as Lindsey premises, with the minimum of change, and the first part of the work is therefore devoted to the investigation of the waste liquors of this process, holding in solution 2–10 per cent. of "total solids." Of these the inorganic constituents are mainly calcium sulphate and sulphite. In the organic constituents the author found small quantities of pentaglucooses, probably xylose, and of galactose or galactan, traces of vanillin, and some quantity of mannose. But by far the larger proportion, say 90–95 per cent. the author finds to be made up of the amorphous or gummy solid which characterises the residue of evaporation. This compound was isolated in a variety of forms, showing a satisfactory uniformity in empirical composition. Of these we may cite the following, omitting the details of the preliminary purification:—

- (a) Precipitated by alcohol, $C_{26}H_{40}O_{12}$ SO
(b) Gums precipitated as lead salts $C_{26}H_{40}O_{12}$ SO
compounds, $C_{26}H_{40}O_{12}$ SO, $C_{26}H_{40}O_{12}$ SO, $C_{26}H_{40}O_{12}$ SO
(c) Precipitated by HCl, $C_{26}H_{40}O_{12}$ SO
(d) Precipitated by Br, $C_{26}H_{40}O_{12}$ Br₂SO

These bodies may be regarded as derived from the compound $C_{26}H_{40}(C_2H_5)_2O_{12}$, which is therefore well established, subject to the conditions premises, as the empirical formula for the lignone constituent of fir-wood.

The insoluble product of the manufacturing process, i.e., sulphite cellulose, was found to be partially converted into dextrose by treatment with concentrated sulphuric acid. By the action of strong nitric acid this cellulose, and also the original wood, was converted into an oxycellulose, having the empirical composition:—

C.....	63.41
H.....	6.19
O.....	50.10

Therefore similar in composition, as it was found to be in its properties, with that obtained by the authors from cotton (Chem. Soc. Jour. 1883).

Such is a brief outline of Lindsey's results, and upon them the authors offer one or two comments.

The empirical formula deduced by themselves for the lignone constituent of jute, from the study of its chlorination products (Chem. Soc. Jour. 1889, 213), was $C_{26}H_{40}O_{12}$, which differs but little from Lindsey's formula (*supra*) for the non cellulose of fir-wood; for—

The proportion of methyl groups in the above formula was determined by the hydriodic acid method; they are therefore present as $O.C_2H_5$ groups. In their paper on the "Constitution of the Jute Fibre Substance" (*loc. cit.*), the authors noted the formation of acetic acid by the solution of the fibre in sulphuric acid, and deduced from the observation that the C_2H_5 groups were in union with CO groups. But conclusions may be true, and would appear to be justified by the study of the products of destructive distillation, of which both CH_3 , CO and OCH_3 groups are prominently characteristic. The authors also obtained methyl chloride by the destructive distillation of the chlorinated derivative of the lignone of jute.

Lindsey does not appear to have attempted to diagnose the mode of union of the S atom in the molecule of the derivative of the lignone. It is important, however, to have established the fact of its presence in combination; and it will no doubt prove to have an important bearing on the theory of this process of cellulose isolation. The authors are engaged, on the other hand, in studying the derivative obtained in the sulphurous acid (Pictet) process of resolving pine-wood, which is of an obviously simpler character, and appears to yield a derivative more closely related to the original lignone than that investigated by Lindsey and Tollens.

Lastly it is noted that Lindsey and Tollens retain the term *lignin* for the non cellulose constituent of the ligno-cellulose; seeing that the characteristics of the body are those of a ketone, we have suggested the substitution of the term *lignone*, which we think preferable.

II.—Oxidation of Ligno-Celluloses by Chromic Acid.

In their earlier contributions to the chemistry of cellulose (Chem. News, 42, 77; Chem. Soc. Jour. 38, 666), the authors noticed that the cellulose isolated by the chlorination method was not homogeneous, containing a form of cellulose easily hydrolysed by acids and alkalis to soluble derivatives; further, that by suppressing or limiting as far as possible the conditions tending to hydrolysis in the process of separating the cellulose, the proportion obtainable, i.e., percentage yield on the raw fibre, could be considerably increased.

Thus, by preventing the rise of temperature in chlorination, and digesting subsequently in aqueous sulphurous acid at 0°, the yield was increased to 80–82 per cent. from the 71–76 per cent. obtainable without these precautions.

These observations led the authors to the conclusion, which we give in the words of our first paper (1880), that "as the cellulose is not homogeneous, and the percentage yield varies with the several methods by which the inter-cellular substances may be removed, they had reason for believing them to contain a body allied to cellulose. The

facts are explained by the hypothesis that the intercellular substance consists of a complicated quinone which is intimately associated with a carbohydrate . . . more closely allied to cellulose than to glucose."

This view the authors are now in a position to confirm and develop from results which they had recently obtained by graduated oxidations of the ligno-celluloses with chromic acid. Of these they take the opportunity of giving a brief preliminary notice.

Chromic acid, in cold dilute aqueous solution, is not deoxidised to Cr_2O_3 by the jute fibre substance; there appears, on the other hand, to be a direct combination and a considerable quantity of the oxide appears to be fixed, probably, in part at least, in the form of the oxides intermediate between Cr_2O and Cr_2O_3 .

The addition of a mineral acid determines the deoxidation, and the fibre is converted into a greenish product, brittle and yet soft to the touch, and of high lustre. Of this product the authors obtained from 85–90 per cent. of the weight of the raw fibre; in this case a jute of medium quality, yielding about 74 per cent. cellulose by the ordinary chlorination method. On ignition it gave an ash containing Cr_2O_3 , equal to from 2–2.5 per cent. of its weight. The organic portion they found to be an *oxycellulose*. The carbon percentage they determined in various specimens; it varies between 43 and 44. It is largely soluble in alkalis, the solution reducing Fehling's solution copiously on boiling.

Pine-wood they found gives similar results, *i.e.*, a high percentage of a product of low carbon percentage, soluble for the most part in cold alkaline solutions, and agreeing in this as in other respects with the well-characterised group of *oxycelluloses*.

The soluble products of the chromic acid oxidation they isolated and found to be brown gummy bodies giving chlorine substitution products with characteristic colour reactions.

By this particular oxidation, therefore, the authors appeared to convert into cellulose (*i.e.*, a derivative of cellulose) a body which, under the treatment hitherto adopted for separating the cellulose, is *hydrolysed* into soluble products. They had on many occasions pointed out that the yellow chlorinated derivative obtained from the fibre contained a *quinone-chloride* associated with a body which gave a copious yield of furfural by acid hydrolysis, and probably, therefore, a *pentagluco*.

It is therefore probable that this pentagluco exists in the fibre in the form of a cellulose (E. Schulze, Ber. 24, 2277). There are many grounds for regarding lignification as a process of modification of cellulose by deoxidation and dehydration, and the action of dilute chromic acid in presence of a hydrolysing acid would appear to confirm this view, while giving the nearest approach which the authors have yet made to the retracing of the process backwards through its several stages.

PATENTS.

An Improved Method of Treating Peat Fibre for the Manufacture of Paper Wrappers, Millboards and the like. J. A. London, Newcastle-on-Tyne. Eng. Pat. 7816, June 30, 1890. 4d.

PEAT fibre is taken direct to the breaking engine and is there mixed with the other material, such as rope, bagging, waste jute, and waste papers. To the mixture rosin size, containing a large excess of alkali, is added, and the temperature raised to 150° F.—E. J. B.

New Process of Sizing Paper. A. Mitscherlich, Freiburg, Germany. Eng. Pat. 11,372, July 21, 1890. 4d.

On adding sulphite liquors in which wood has been boiled to a solution of gelatine, the latter is precipitated in a "highly cementitious and adhesive condition." The precipitate is dissolved in slightly alkaline water, and is reprecipitated in the pulp by the addition of alum. (Compare this Journal, 1883, 541.)—E. J. B.

Improvements in the Manufacture of Pearl Hardening. J. Beveridge, Gravesend. Eng. Pat. 12,400, August 8, 1890. 6d.

PEARL hardening or crystallised calcium sulphate is prepared by the double decomposition of solutions of sodium sulphate and calcium bisulphite. The resulting solution of sodium bisulphite is sold as such, or it may be applied to a variety of uses in paper mills.—E. J. B.

Improvements in the Method of Obtaining Useful Products from Bleaching Powder Dregs and Lime Mud from Paper Works. T. J. Hutchinson, Manchester. Eng. Pat. 13,504, August 28, 1890. 4d.

INSTEAD of repeatedly washing with water the waste residues from the production of bleach liquor or caustic soda liquor, the inventor treats these residues at once with a solution of sodium carbonate, so as to utilise any lime present in the residues for the production of caustic soda. The treated residue is collected in a filter press, dried and calcined for the reproduction of caustic lime.—G. H. B.

Improvements in Photographic Sensitised Films or Cards. H. Kuhn, Springfield, U.S.A. Eng. Pat. 6921, April 22, 1891. 6d.

THE inventor renders cardboard waterproof by dipping it in a "solution of insoluble soap." After being covered with celluloid varnish it is coated with a mixture of barium sulphate and gelatine. When this is dry the boards are passed between polishing rollers and are then coated with an emulsion prepared by mixing together alcohol, ether, pyroxilin, chloride of strontium, an aniline colour, and nitrate of silver.—E. J. B.

Improvements in the Manufacture of Pearl Hardening. J. Beveridge, Gravesend. Eng. Pat. 7797, May 6, 1891. 4d.

INSTEAD of the sulphate of soda specified in Eng. Pat. 12,400 of 1890 (see above) the inventor uses a solution of sulphate of magnesia for the purpose of decomposing a solution of bisulphite of calcium.—E. J. B.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Hypoidous Acid. A. Schwieker. Chem. Zeit. 1891, 15, 630.

See under XXIII., page 805.

The Spontaneous Inflammability of Carbon Disulphide. M. Pöpel. Chem. Zeit. 15, 822–823.

THE causes governing the spontaneous ignition of carbon disulphide are obscure, and the following case may be useful as serving to elucidate one of them. On account of the volatility of carbon disulphide great difficulty is experienced in working with it, it being impracticable to prevent its escape through the cocks, manholes, &c., of the extraction apparatus in which it is used even at trifling pressures such as 9.1 of an atmosphere. The air which finds its way into the apparatus each time it is opened also carries away a considerable amount. While experimenting, in order to diminish the loss thus caused, the author attached a tube to the end of the exit pipe dipping into oil to the depth of about 10 cm., and found that absorption was fairly complete, and that though the amount of carbon disulphide vapour carried off when the temperature of the cooling

water was only 10—12° C., yet when it rose 8—10° C. the loss amounted to several litres in a few hours. On account of the addition of the absorption vessel the pressure in the apparatus rose to about one-eighth of an atmosphere, and the boiling of the liquid in the still was consequently affected. While a workman was removing the pipe and the oil vessel was lowered to give him more room for that purpose, it was observed that the pipe became hot at the bend, and an explosion followed which set fire to the oil saturated with carbon disulphide. The author attributes this occurrence to the mixture of vapour and air in the pipe being raised to its ignition point by friction. A direct experiment, consisting in allowing a little carbon disulphide to evaporate in a copper oven, showed that ignition would take place at 98—99° C. Copper has apparently some specific action inducing the combination, as on coating the sides of the oven with clay no such effect was produced. Iron steam-pipes at a temperature of 135—145° C. (= 3—4 atmospheres) will ignite a mixture of carbon disulphide and air; all steam-pipes should therefore be lagged where such a mixture is likely to come into contact with them. The more air is present the higher the temperature of ignition and the more violent the explosion.

In conclusion, the author recommends the adoption of as low pressures as are possible without the use of a partial vacuum, recourse to which is forbidden by the risk that would be incurred by the explosion of a mixture of carbon disulphide vapour and air during compression in the pump cylinder. Where plenty of cold water for condensation is available the loss is small, but in any case the plant should be under careful and intelligent control.—B. B.

On Benzoyl-Guaiacol as a Substitute for Cresols.

F. Walzer. Chem. Zeit. Rep. 1891, 15, 165.

Cresols are one of the most useful medicines in lung diseases, but it has a disagreeable taste and not infrequently gives rise to inflammation of the mucous membrane of the stomach. The author attributes the evil effects to the cresolic substances present and the good effects to the guaiacol. But as guaiacol also possesses an objectionable taste and smell, the author proposes the use of Bongart's "Benzosol" (benzoyl-guaiacol)—

This substance can be obtained free from injurious impurities, as well as from taste and smell. It becomes decomposed in the stomach into guaiacol and benzoic acid, and, according to the hospital experience of the author, its use as a substitute for cresols has a favourable effect on digestion and has a strengthening influence on the patient.—G. H. B.

The Properties of Diethylendiamine (Piperazine). A.

Ladenburg. Ber. 24, 2100—2102.

The quantity of piperazine furnished as a commercial product being now such that exact observations and experiments are rendered more easy than formerly, the author has availed himself of opportunities thus occurring.

Nitroso piperazine, $\text{C}_4\text{H}_{10}\text{N}_2(\text{NO})$, is easily prepared by treating a solution of piperazine hydrochloride containing some free hydrochloric acid, with nitrate of soda, and warming the mixture for a short time. A crystalline body thus separates out, which is once or twice recrystallised from water. A solution of phenol in concentrated sulphuric acid (Liebermann's reagent) is coloured strongly by this nitroso-compound, and becomes, after a few minutes, deep blue. Melting point = 158°. It is with difficulty soluble in cold water and ether, easily in hot water and hot dilute alcohol.

N-Dimethylpiperazine, $\text{C}_6\text{H}_{12}\text{N}_2(\text{CH}_3)_2$.—An aqueous solution of piperazine is warmed with an excess of methyl-potassium sulphate for several hours in connexion with an inverted condenser until the alkaline and nitroso reactions

have disappeared. Supersaturation with soda follows, and distillation so long as the base distils over. The latter is then evaporated down with hydrochloric acid, and the residue recrystallised from alcohol.

The Base itself is easily separated from the hydrochloride by means of alkalis, is easily volatile, and possesses a penetrating odour, similar to that of methylamine.

New Compounds of the Camphor Group and a New Terpene. O. Wallach. Annalen, 1891, 263, 129—156.

This paper is a continuation of the author's researches on Fenchol, the geometrical isomeride of camphor, for which it is now proposed to substitute the name Fenchon, on account of its ketonic nature. (This Journal, 1890, 1147.)

Fenchon, $\text{C}_{10}\text{H}_{16}\text{O}$.—To prepare this body, the portion of fennel oil of boiling point 190°—195° C. is treated with nitric acid (concentrated), when the anethol and other impurities are oxidised, whilst the fenchon is left unchanged. The product of the reaction is poured into water, the separated oil washed with caustic soda, distilled with steam, dried, and finally crystallised at a low temperature. The pure product boils at 192°—193°, and has a specific gravity of 0.9165 at 19° C. (not 0.934 at 23° as given in the abstract mentioned above). On prolonged cooling at a low temperature it solidifies in large crystals, melting at 5—6° C. Its index of refraction is $n_D = 1.46306$ at 19° C., corresponding to a molecular refractive power = 44.23, whereas a compound $\text{C}_{10}\text{H}_{16}\text{O}$ without ethylene bonds requires 44.11. It is dextro-rotatory $[\alpha]_D = +71.97$. Bromine forms an unstable crystalline addition-product with fenchon in the cold; on warming, both bromine and iodine yield substitution products. Fenchon is dissolved unchanged by cold hydrochloric or sulphuric acid, nitric acid only attacks it on prolonged heating, and then but slowly, organic acids and hydrocyanic acid being among the products of decomposition. It is oxidised by potassium permanganate, when dimethyl-malonie, acetic, and oxalic acids are formed. Fenchon and camphor have a similar physiological action. The former does not react with either phenylhydrazine or with acid sulphites of the alkalis, but yields a crystalline oxime with hydroxylamine (*cide* previous abstract). The melting point of this body varies with the method of heating from 150—165° C., owing to its losing water and forming an anhydride, $\text{C}_{10}\text{H}_{14}\text{N}$, which is most readily got by warming the oxime with sulphuric acid (dilute). This anhydride boils at 217—218° C., is dextro-rotatory, and appears to be an unsaturated body, combining readily with bromine and with the halogen hydracids. When treated with sodium amalgam in alcoholic solution it yields a base, $\text{C}_{10}\text{H}_{17}\text{N}$ ($\text{C}_{10}\text{H}_{17}\text{N} \cdot \text{HCl}$), which boils between 250° and 260° C. Like the anhydride or nitrile, it appears to be an unsaturated body, forming a hydrochloride, $\text{C}_{10}\text{H}_{19}\text{N} \cdot 2\text{HCl}$. Fenchon reacts similarly to camphor with ammonium formate to form the formyl compound of a base, *fenchylamine*, from which the free base, $\text{C}_{10}\text{H}_{17}\text{N}$, is readily isolated. This latter is a liquid having a smell resembling both that of piperidine and of bornylamine. It boils at 195° C., and has a specific gravity of 0.9095. Of the salts, the hydrochloride and sulphate are readily soluble in water. The base is a primary one, and acetyl, benzoyl, and alkyl substitution products have been prepared from it. It is laevo rotatory, $[\alpha]_D = -21.63$. With nitrous acid a peculiar neutral oil is formed, which is under investigation, but neither the corresponding alcohol nor a diazo-compound results. The alcohol, *Fenchyl-alcohol*, $\text{C}_{10}\text{H}_{17}\text{OH}$, the analogue of borneol, is obtained by reducing fenchon with sodium in alcoholic solution. It forms well-characterised white crystals melting at 40°—41° C. and boiling at 201° C. The vapour has a penetrating smell slightly resembling that of borneol. The alcohol is insoluble in water, soluble in alcohol and ether, but does not form addition products with bromine or with the halogen hydracids as borneol does. It is laevo rotatory, $[\alpha]_D = -10.35$. Treated with strong nitric acid it is readily oxidised to fenchon. Phosphorus pentachloride converts the alcohol into the corresponding chloride, $\text{C}_{10}\text{H}_{17}\text{Cl}$, a liquid boiling between 84° and 86° C.,

which, like bornyl chloride, is converted into a terpene, $C_{10}H_{16}$, when heated with aniline. This body, to which the name *Fenchene* is given, is a liquid boiling at 158° – 160° C., readily volatile with steam, and optically inactive. Its refractive index points to the presence of an ethylene bond, as does the ease with which it reacts with bromine. It is very stable towards nitric acid; on oxidation with potassium permanganate a monobasic hydroxy acid, $C_{10}H_{16}O_3$, results, the nature of which is being worked out. The paper concludes with theoretical considerations as to the relation which fenchon and its derivatives bear to camphor.—C. A. K.

Terpenes and Etheral Oils. O. Wallach. *Annalen*, 1891, 264, 1–32.

Pinene.—It is generally believed that pinene readily takes up a molecule of bromine to form a liquid dibromide, $C_{10}H_{16}Br_2$, which when treated with alcoholic potash gives off hydrobromic acid and forms cymene. On the other hand Tilden has shown (*J. Chem. Soc.* 1888, 82) that pinene, like limonene and dipentene, can absorb 2 molecules of bromine. The author has re-investigated the reaction and finds that when 1 molecule of the hydrocarbon is treated with 1 molecule of bromine, absorption occurs very readily, but that some hydrobromic acid is always liberated. The product of the reaction when treated with alcoholic potash yields a complex mixture consisting of camphene, undecomposed pinene hydrobromide, a crystalline pinene dibromide, and perhaps a very small quantity of cymene, which last was not however detected with certainty. The crystalline dibromide, which has the formula $C_{10}H_{16}Br_2$, forms hexagonal colourless crystals melting at 169° – 170° C., soluble with great difficulty in cold alcohol, readily soluble in chloroform and in warm acetic ester. The yield obtained is only 7 per cent. Neither camphene nor pinene hydrobromide yield it when treated as above, so that it is to be regarded as a direct product of the action of bromine upon pinene. It is optically inactive and does not form addition products. When heated with aniline, cymene is formed.

Limonene, when treated with 2 molecules of bromine yields in addition to the crystalline tetrabromide, $C_{10}H_{16}Br_4$, a liquid tetrabromide which is regarded as a physical isomeride of the former. The crystalline, dextro-rotatory tetrabromide when heated with alcoholic potash, is converted into a liquid monobromide, $C_{10}H_{15}Br$, also dextro-rotatory, 3 molecules of hydrobromic acid being most probably split off thus:— $C_{10}H_{16}Br_4 = C_{10}H_{15}Br + 3 HBr$. This monobromide reacts with hydrobromic acid to form the inactive limonene tetrabromide, viz., dipentene tetrabromide. Aniline reacts differently to alcoholic alkali with limonene tetrabromide, only a small quantity of hydrocarbons resulting amongst which a mono-alkylated benzene, probably propylbenzene and cymene, were detected.

Dipentene.—Dipentene dihydrobromide, $C_{10}H_{16} \cdot 2HBr$, treated with bromine, is converted into a crystalline tribromide, $C_{10}H_{17}Br_3$, which forms snow-white plates melting at 110° C. Heated with sodium in alcoholic solution a hydrocarbon, $C_{10}H_{14}$, is formed, isomeric but not identical with cymene. It boils at 183° – 184° C. and absorbs bromine very readily to form a well defined crystalline tetrabromide, $C_{10}H_{11}Br_4$, which melts at 154° – 155° C., and also a second tetrabromide of the same formula, melting at 103° – 104° C. This latter could not be obtained crystalline, but only in an amorphous condition. The study of the action of chlorine on dipentenedihydrochloride has also been begun by the author, a tri- and tetra-chloride, $C_{10}H_{17}Cl_3$, and $C_{10}H_{16}Cl_4$, having already been isolated.—C. A. K.

Strychnine. J. Tafel. *Annalen*, 1891, 264, 33–84.

AFTER a review of the attempts that have been made to elucidate the constitution of strychnine, the author gives full details of his own experiments, with the same object in view.

Loebisch and Schoop (*Monatsh. Chem.* 7, 83), have shown that strychnine treated with alcoholic soda yields a body to which they gave the name of "*strychnol*," which has been

shown by the author (this *Journal*, 1890, 1061), to have the formula $C_{20}H_{22}N_2O_3$, being formed by the addition of H_2O to the strychnine molecule. This substance possesses phenolic properties, but further experiments have shown that it is not a phenol, but an imido-acid, for which the name "*strychnic acid*" is proposed. The alkaloid itself is to be regarded as the anhydride of this acid, the two bodies standing in the relation of isatic acid to isatine:—

The presence, both of the imido-group and of the carboxyl group in strychnic acid is pointed to by the action of nitrous acid, by the introduction of acid radicles and by the formation of esters. The two latter reactions are complicated by the fact that the acid regenerates strychnine on treatment with mineral acids. The sodium salt of strychnic acid reacts with methyl iodide in alcoholic solution, to form the methiodide of strychnic acid, also a secondary base, which, when treated with mineral acids, behaves similarly to strychnic acid and forms strychnine methiodide, the product obtained by direct treatment of strychnine with methyl iodide:—

When the sodium salt of this methiodide of strychnic acid is treated with an excess of methyl iodide in methyl-alcohol solution two methylated bodies result, standing in the relation of a methyl ester to its acid, as was proved by converting the one into the other. These products are:—

the formation of which points decisively to the presence of the imido group and of the carboxyl group in strychnic acid. The silver salt of the methiodide of strychnic acid loses silver iodide on gentle warming with water and forms methyl strychnine, which is to be regarded as the methyl-beta-in of strychnic acid, an ammonium hydrate having been formed as an intermediate product:—

The silver salt of the methiodide of methyl strychnic acid reacts similarly to form the corresponding compound in which the hydrogen of the imido-group is replaced by methyl, viz.:—

Methyl strychnine is a secondary amine and forms a nitrosamine; dimethyl strychnine is a tertiary amine and forms a nitroso-compound closely resembling the nitroso-compound of dimethylaniline, with which base it shows

further analogy in reacting both with benzaldehyde and with diazobenzene sulphonic acid to form a green and a yellow colouring matter respectively. These reactions point undoubtedly to the $\text{N} = \text{CH}$ group in dimethyl strychnine and consequently the $\text{N} = \text{CO}$ group in strychnine itself, being attached to a benzene ring by one valency. Attempts to decompose the nitroso-dimethyl-strychnine by alkali similarly to nitroso-dimethyl-aniline, with the formation of a substituted methylamine were unsuccessful.

Two other products, produced by the action of baryta-water on strychnine at 130° have been described by Galand Etard, to which the names of *dihydrostrychnine* and *trihydrostrychnine* have been given respectively. The former of these bodies has the composition $\text{C}_{21}\text{H}_{26}\text{N}_2\text{O}_4$, and according to the researches of the author is an isomeride of strychnine acid, containing one molecule of water of crystallisation, which it loses at 135° C. This *isostrychnine acid* is stable towards mineral acids, with which it forms salts, differing essentially in this from strychnine acid. Concentrated hydrochloric acid acts on the iso-acid at 100° C. to form a body reacting similarly to strychnine, which could not however be obtained in a crystalline condition and which has not yet been examined in detail; the acid has similar poisonous properties to strychnine. The iso-acid forms a nitrosamine, and reacts with alcohol and with acetic anhydride to form an ester and acetyl compound respectively, which crystallise with difficulty. Methyl iodide forms a methiodide with the sodium salt of the iso-acid and the sodium salt of the former reacts further with methyl iodide on similar lines to the corresponding compound of the normal acid to form methyl-iso-strychnine acid methiodide, and its methyl ester. Iso-methyl-strychnine and iso-dimethyl-strychnine have also been prepared from the silver salts of the corresponding iso-compounds; these behave similarly to the normal compounds in their reactions, but differ in their physical properties. The cause of the isomerism requires further investigation.

Full details of the methods of preparation and properties of the substances dealt with in the memoir are given.

—C. A. K.

Stability of Hydroxylamine. V. Meyer. *Annalen*, 1891, 264, 126.

HYDROXYLAMINE is not completely decomposed by boiling with concentrated caustic fixed alkali, as is generally supposed, and hence this reagent does not serve to remove the base completely from solutions when required. It is, however, completely destroyed by treatment with platinum chloride and hydrogen being reduced to ammonia, as previously shown by the author. On the decomposing action of ferric chloride, platinum chloride, &c., Lossen and others have repeatedly written.—C. A. K.

Phenocolum Hydrochloricum, a New Antipyretic. Schering. *Apoth. Zeit.* 1891, 6, 247.

This new antipyretic is the hydrochloride of amidocetiparaphenetidine—

and results from the condensation of glycoic and phenetidine. It forms a white micro-crystalline powder soluble in about 16 parts of water and crystallising therefrom in cubes. From alcoholic solution it separates in needles which melt at 95° C. Ammonia, caustic potash, and the alkaline carbonates separate the base from an aqueous solution of the hydrochloride in the form of fine needles, which contain 1 molecule of water of crystallisation. Phenetidine and glycoic are regenerated on prolonged boiling with the alkaline hydrates or carbonates. Doses of 0.5–1.0 gm. of the hydrochloride act most successfully in cases of nervousness or neuralgia, whilst daily doses of 5 grams have given good results in cases of rheumatism in the joints, when antipyrine, antifebrine, and sodium salicylate were of no avail.—C. A. K.

The Physiological Action of Paraphenetidine. L. Reuter. *Pharm. Zeit.* 1891, 36, 185.

PARAPHENETIDINE, which is found as an impurity in phenacetine, is poisonous, and when given for some time in very small doses affects the kidneys, producing *nephritis*. It is therefore very necessary always to test phenacetine for *p*-phenetidine.—C. A. K.

Conversion of Cupreine into Quinine. O. Hesse. *Pharm. Zeit.* 1891, 36, 289.

THE author observes that Grimaux and Arnaud, (*this Journal*, 723–724) who claim the production of quinine from cupreine by the action of methylic chloride on cupreine sodium, have not stated the yield. He therefore thinks it possible that the cupreine experimented upon might have contained quinine as an impurity.

But even if the conversion has really been successful it will simply be a matter of scientific, not practical, interest, as cupreine is, after all, an alkaloid procurable with difficulty.—L. de K.

A Violet Colouring Matter from Morphine; the Formula of Pseudomorphine. P. Cazeneuve. *Bull. Soc. Chim.* 1891, 5, 857–863.

See under IV., page 754.

Resoppyrine. L. Roux. *J. Pharm. Chem.* 1891, [5], 23, 282.

WHEN concentrated solutions of antipyrine and of resorcinol in molecular proportions are mixed together a white precipitate is formed with which a few oily drops are mixed up. On stirring, the oily compound increases in quantity, forming a thick mass which after 1–2 minutes becomes hard. The resulting product is insoluble in water, only slightly soluble in ether, but fairly so in alcohol, from which solution it separates in white crystals which melt readily on heating. *Resoppyrine* is the name given to the new compound, the composition of which has not been ascertained. It has no smell but a slightly biting taste; the alcoholic solution is not precipitated by water. It is coloured orange-red by sulphuric acid, red by nitric acid, and blood-red by ferric chloride.—C. A. K.

Preparation of Hypnal or Monochloralantipyrine. Demandre. *Répert. de Pharm.* 1891, 47, 107.

FORTY-SEVEN GRMS. of chloral hydrate are dissolved in 50 grms. of water, and a solution of 53 grms. of antipyrine also in 50 grms. of water added. The mixture is well shaken in a separating funnel and allowed to stand when it separates into an aqueous and an oily layer, the former floating on the latter. After standing for one hour the two liquids are run separately into evaporating dishes and there allowed to stand for 24 hours, when the oily layer solidifies to form transparent rhombic crystals. A few crystals also separate from the aqueous solution. The crystals are purified and finally dried between filter paper or over sulphuric acid in an exsiccator.—C. A. K.

Method for Purifying Carbon Bisulphide without Distillation. A. Chenevier. *L'Union Pharm.* 1891, 32, 201.

ONE litre of the carbon bisulphide is treated with 0.5 cc. of bromine and allowed to stand for 3 to 4 hours. The excess of bromine is removed by agitation with caustic potash or copper turnings. Any remaining cloudiness may then be removed by agitation with a little dry calcium chloride with subsequent filtration. The carbon bisulphide treated in this way is colourless, of pleasant smell, and evaporates without residue.—G. H. B.

Bromoform. G. Beringer. Amer. J. Pharm. 1891, **63**, 80.

THE author was unable to obtain satisfactory results with Günther's method for the preparation of bromoform, and has worked out the following modification of Dumas' method. 120 grms. of lime are slaked and placed in a flask attached to a condenser and provided with a dropping funnel. The stopper of the flask carries in addition a tube reaching into the flask and connected at its upper end by means of a piece of rubber tubing to a rubber ball which serves to blow a current of air into the mixture and thus to keep the whole well agitated. 120 grms. of acetone are then added gradually, the mixture warmed gently to 45°–50° C. and then bromine added slowly until the liquid is coloured permanently yellow. When the reaction is completed, lime-water is added to alkaline reaction and the liquid distilled. The first portion of the distillate contains the bromoform, which is separated, washed with water, dried over calcium chloride and distilled. The product of boiling point 143°–148° C. is placed in a freezing mixture and the portion that solidifies at + 6° C. separated as quickly as possible from adhering liquid. The crystals, which may be considered as chemically pure bromoform, have a sp. gr. of 2.900 at 15° C. and boil at 147°–148° C.

According to the author, bromoform used medicinally should boil at 147°–150° C. and should not be coloured either by strong sulphuric acid or by caustic potash. When shaken with water the aqueous solution should not give an acid reaction, nor a precipitate with silver nitrate, nor reduce the latter reagent with the formation of a mirror. The vapours of the sample should not irritate the membrane either of the eyes or of the nose.—C. A. K.

The Present Commercial Importance of Saccharine and the Attitude of the Beetroot Industry with Reference to the Exemption of this Substance from Taxations. F. v. Thümen. Chem. Zeit. 1891, **15**, 634–635.

See under XVIII. A., pages 784–785.

PATENTS.

Improvements in the Manufacture of Oxyphthalic Acids (Phenol Dicarboxylic Acids). J. Y. Johnson. From F. von Heyden, Dresden, Germany. Eng. Pat. 12,993, August 19, 1890. 4d.

THE alkali salts of the alkyl esters of 1 : 3 and 1 : 4 hydroxybenzoic acid are treated in an anhydrous condition with carbon dioxide in an autoclave at a temperature of 140°–180° C., the product of the reaction dissolved in water and the ester of the hydroxydicarboxylic acid precipitated by the addition of a mineral acid. The alkyl group attached to the carboxyl is then removed by hydrochloric acid or other suitable means and the free dicarboxylic acid obtained. In this manner the following acids are formed:—(1.) the β -hydroxy-phthalic acid of Reimer and Tiemann; (2.) the hydroxy-terephthalic acid of Burkhardt and Jacobsen; (3.) the α -phenol-dicarboxylic acid of Ost, from the esters of 1 : 2, 1 : 3, and 1 : 4 hydroxybenzoic acids respectively. The following equation represents the reaction:—

Improvements in the Manufacture of "Spermine." W. Majert, Berlin, Germany. Eng. Pat. 15,404, September 29, 1890. 6d.

"Spermine" is the name given by Schreiner to a base, $\text{C}_2\text{H}_5\text{N}$, found in human and in animal sperm, and which, according to Ladenburg (Ber. **21**, 758), is ethylenimine—

which in aqueous solution should be easily condensable to piperazine or piperazidine—

The author finds that the product has this latter formula, and that it is produced by the action of alkalis or of alkaline earths or of mixtures of the two upon the following bodies:—

Dinitroso-	}	Diphenyl-piperazine.
Dinitro-		Ditolyl-piperazine.
Trinitro-		Dixylyl-piperazine.
Tetranitro-		Dimesityl-piperazine.
Pentanitro-		Dipseudocumyl-piperazine.
Hexanitro-		Dinaphthyl piperazine.
Di-chlor-		
Trichlor-		
Tetrachlor-		
Pentachlor-		
Hexachlor-		

The dichlor, &c. compounds may be substituted by the corresponding bromo- or iodo-piperazines.

One part by weight of the above is treated with 2 to 4 parts by weight of 25 per cent. caustic soda or potash. From dinitroso-diphenyl-piperazine, one molecule of piperazine and two molecules of nitrosophenol result. The mixture is distilled, when the piperazine passes over with the steam, and is neutralised in the distillate by hydrochloric, phosphoric, or sulphuric acid. Water is employed as the solvent for the alkalis or alkaline earths; when the latter are used it is advisable to work under pressure in closed vessels and at a rather higher temperature. The free base has the smell of sperm, and is very soluble in water, from which it crystallises in glittering four-sided tables. The hydrochloride, which is employed in medicine, forms needles containing water of crystallisation. Very weak, slightly acid solutions of this salt give a pomegranate-coloured crystalline precipitate with bismuth-potassium iodide, and a yellow precipitate with picric acid. The gold double chloride forms small yellow glittering scales. (Compare this Journal, 1891, 381.)—C. A. K.

A Receiver for the Preservation and Application of Chloride of Ethyle. B. J. B. Mills, London. From Messrs. Auguste Gilliard, Prosper Monnet, and Jean Marie Cartier, Lyons, France. Eng. Pat. 16,392, October 15, 1890. 4d.

THE ethyl chloride is enclosed, immediately after its manufacture, in glass flasks, each containing the quantity usually necessary for an operation—about 10 grms. The flasks are cylindrical and have a slender neck, which is hermetically sealed after filling. The slender neck of the flask is broken off at the most contracted part, which is indicated by a file mark, when required for use, and as the ethyl chloride boils at + 10° C. it vaporises immediately and issues in a fine jet of vapour. A liquid jet can be obtained by laying the flask down or by turning it upside down. By heating the flask more or less by the hand the strength of this liquid jet can be regulated at will. By simply placing the finger over the mouth of the flask the jet of liquid or vapour can be stopped.—C. A. K.

Improved Manufacture of Pepsin. J. Le Roy Webber. Detroit, U.S.A. Eng. Pat. 5981, April 7, 1891. *Id.*

THE mucous membranes from animals' stomachs, especially those of the pig, are digested with acidulated water or with weak hydrochloric acid at 40–50° C., sufficient sulphurous acid then added to prevent decomposition, and the whole allowed to clarify by standing. The comparatively clear liquid is next drawn off and saturated with sodium sulphate, preferably at about 34° C., which precipitates the pepsine. This is collected, pressed and dried, and forms the crude product from which the pure pepsine is prepared; it is, however, very active itself, and is marketable. The purification is effected by dialysis, the sulphate of sodium and peptone passing into solution, whilst the pepsine remains behind. More than 90 per cent. of the sodium sulphate employed can be thus recovered. The purified pepsine is practically devoid of offensive odour; it is not hygroscopic, and is of superior digestive strength, being quite free from the inactive peptone.—C. A. K.

Improvements in the Manufacture of Ortho-oxyquinoline and Oxyquinoline Derivatives. A. Lembach and F. Schleicher, Biebrich, and C. J. Wolff, Wiesbaden, Germany. Eng. Pat. 7863, May 6, 1891. *Id.*

ORTHO-AMINO-PHENOL-PARA-SULPHONIC acid, ortho-nitro-phenol-para-sulphonic acid, glycerol, and sulphuric acid are boiled together for about 6 hours in a suitable vessel provided with an inverted condenser and the resulting molten mass diluted with water. The whole is then neutralised with caustic soda, and the hydroxyquinoline, which is completely precipitated, separated by filtration and purified by distillation with steam. By boiling this product with sulphuric acid and water for 6 hours and evaporating off the excess of liquid in a vacuum pan, the neutral sulphate, $(C_8H_7O.NH_2).H_2SO_4$, is obtained in the form of sulphur yellow crystals. Or instead of separating the water in a vacuum pan, the liquid can be evaporated on a water-bath, or by means of steam, when a honey-like yellow syrup is obtained which when digested with a mixture of alcohol and ether yields the sulphate as a fine yellow powder melting between 170 and 180° C.

The phenol sulphamate of 1:2 hydroxyquinoline, $C_8H_5(OH).N(C_6H_5)(OH)(SO_3OH)$, is prepared by boiling a mixture of molecular proportions of 1:2 hydroxyquinoline and 1:4 phenol sulphonic acid with water for about a whole day in a vessel provided with an inverted condenser. A 50 per cent. solution of the product results, which, when concentrated in a vacuum pan below 100° C., yields a yellow syrup which does not crystallise readily. The phenol sulphamate is very soluble in water. Similar compounds of 1:2 hydroxyquinoline with 1:2 phenol sulphonic acid, with 1:2 and 1:4 cresol sulphonic acid and with sulphosalicylic acid (hydroxyquinoline sulphosalicylate, $C_8H_5(OH).N(C_6H_5)(OH)(OH)(SO_3OH)$) are obtained on analogous lines to the above phenol sulphamate. Further, other phenols or their derivatives may be employed in the preparation of 1:2 hydroxyquinoline derivatives, and in the preparation of the 1:2 hydroxyquinoline itself the 1:2 intraphenol 1:4 sulphonic acid may be substituted by nitrobenzoic, picric acid, or other suitable oxidising agents. —C. A. K.

Improvements in the Manufacture of Medical Extracts. P. A. Newton, London. From the American Embury Company, New York, U.S.A. Eng. Pat. 8541, May 19, 1891. *Id.*

THE process consists in obtaining medicinal extracts from vegetable substances by means of "petroleum jelly" (vaselin). The jelly is allowed to percolate through a suitable vessel containing the substance to be extracted, the whole being kept at such a temperature that the solvent is perfectly liquid (120–140° F.). On the vegetable substances may be steeped in the warmed jelly. After extraction the jelly is strained or filtered. Mustard, cloves, coffee, cinnamon, bay leaves, cinchona bark, &c., may be

extracted in this manner. The patent further covers the production of a medicinal preparation consisting of the said jelly, having absorbed within it the active principle of a vegetable substance.—C. A. K.

Manufacture of Pyrazolones. O. Imray, London. From C. F. Boehringer Söhne, Waldhof, near Mannheim, Germany. Eng. Pat. 9923, June 26, 1891. *6d.*

PYRAZOL derivatives are produced by the action of β -halogen substituted fatty acids or of their esters on phenylhydrazine, the substances being heated together on the water-bath and the product of the reaction then separated by the addition of water. From β -chloropropionic acid or its ester *phenylpyrazine* (*phenylhydropyrazolone*)—

results.

This body forms fine flat needles or plates which melt at 121° C. and are readily soluble in alcohol and in chloroform. When treated with a mild oxidising agent such as mercuric oxide, in benzene or chloroform solution, it is converted into *dehydro-phenyl-pyrazine* which crystallises in fine needles melting at 154° C. This body has the following constitutional formula:—

From this, *dehydro-methyl-phenyl-pyrazine* is obtained by the action of methyl iodide and wood spirit at 100° C., a body which possesses valuable antipyretic properties. It is readily soluble in water and crystallises from chloroform in large crystals which melt at 120° C.—C. A. K.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Stability of Hydrargyramine. V. Meyer. *Annalen*, 1891, 264, 126.

See under XX., page 790.

PATENTS.

Improvements in the Manufacture of Transparent Flexible Films for Photographic and other Purposes. J. W. Swan, Bromley, and J. Leslie, Belfast. Eng. Pat. 9893, June 26, 1890. *Id.*

A SOLUTION of nitrocellulose or celluloid is distributed by means of a machine or in any other suitable manner, upon or over a surface of paper, linen, cotton, or any other suitable flexible material, previously prepared with a surface of gelatine or other substance unaffected by the nitrocellulose or celluloid solution, calendered or polished with talc, &c. After coating, the flexible support must be kept level until the solution sets, when it may be hung up to dry. The film is then stripped from the support. If intended for photographic purposes the film is coated with the sensitive emulsion either before or after stripping.—C. H. B.

Improvements Relating to the Manufacture of Flexible Films for Photographic and other Purposes, and to Apparatus for Use in such Manufacture. B. J. Edwards, London. Eng. Pat. 11,945, July 30, 1890. 8d.

THE specification describes and illustrates an apparatus for recovering the solvents used in the manufacture of flexible films by passing the coated support through a heated chamber from which the vapours are driven or drawn into a refrigerating and condensing apparatus. The support used is preferably a plate or slab of glass, and after the dried film has been coated with the sensitive emulsion these slabs are passed into a special drying chamber containing horizontal racks placed one above the other and capable of movement in a vertical direction.—C. H. B.

Improvements in Apparatus applicable for Use in Photography. T. B. Sloper, Devises. Eng. Pat. 12,014, July 31, 1890. 8d.

THIS patent relates to holders made of wire for lifting plates out of developing dishes and holding them during washing, also for keeping prints separate whilst washing. The holders for plates grasp them round opposite corners. In the case of prints, wires or threads are passed across from one end of the wire holder to the other, in order to form a network on which the print rests.—C. H. B.

Improvements in the Manufacture of Photographic Films. J. J. Aeworth, London. Eng. Pat. 13,836, September 3, 1890. 4d.

A BAND of American cloth or other suitable material is coated with a strong solution of gelatine or an analogous substance, such as isinglass, containing glycerol or some similar compound in order to make it pliable. When the film of gelatine is dry it is stripped off the support and wound on a roller. The film is then passed through a solution of nitrocellulose or pyroxylin, which makes it waterproof, or nearly waterproof, on both sides. The pyroxylin solution contains from 3 to 6 per cent. of pyroxylin dissolved in a mixture of amyl alcohol and amyl acetate. The film is afterwards dried by passing dry air over the surface, or by placing it in a room kept at a suitable temperature, or by passing it through a specially constructed chamber containing air heated to about 200° F.

—C. H. B.

Improvements in or connected with Photographic Spotting or Re-touching. F. C. D. Beacham, London. Eng. Pat. 2390, February 10, 1891. 6d.

A COLOURED crayon for spotting or re-touching is made by melting together, and heating at a high temperature, white wax, soap, "salts of nitre," pitch, shellac, calcined lamp-black, and brown, scarlet, blue, and violet powders in varying proportions according to the colour required.

—C. H. B.

Improvements in Photography. A. J. Boulton, London. From J. North, New York, U.S.A. Eng. Pat. 8557, May 19, 1891. 6d.

GUAIARETIC acid, $C_{20}H_{26}O_4$, when freshly prepared, is soluble in alcohol, ether, carbon bisulphide, chloroform, acetic acid, benzene, &c., but when the free acid, or its salts with metallic or organic bases, or its haloid substitution derivatives and their salts, are exposed to light, they become more or less insoluble in the solvents named. The addition of small quantities of Aniline violet, Magenta, Safranine, and other colouring matters, accelerates the action of the light. Guaiaretic acid is prepared by concentrating to a thin syrup a filtered solution of two parts of guaiacum in 10 parts of alcohol and adding a warm concentrated solution of 1 part of potassium hydroxide. After 24 hours the pulpy mass is pressed through a filtering cloth, and the solid matter washed with alcohol and then with water, and finally crystallised from dilute alcohol.

One hundred parts of the acid, or 120 parts of its silver, zinc, lead, or magnesium salt with or without 3 to 4 per cent. of Aniline violet or other colouring matter, are dissolved in 500 parts of pure benzene. $7\frac{1}{2}$ parts of dry caoutchouc is also dissolved in 500 parts of benzene, and the two solutions are thoroughly mixed and spread in the dark on a well cleaned surface of glass, metal, &c. The dried film is exposed behind a transparent negative or positive to bright sunshine for 10 to 12 minutes, and is developed by means of a mixture of one part of benzene and five parts of turpentine, or some similar liquid. The plate is then dried and etched by some acid according to the nature of the support.

Another method is to mix a neutral aqueous solution of 10 parts of guaiaretic acid (neutralised by any alkali) with 100 parts of a dilute solution of gelatine. A well-cleaned surface is coated with this mixture and dried in a horizontal position at a temperature not exceeding 120° F. The film is then put into a dilute solution of any suitable acid in order to precipitate guaiaretic acid in the film, or into a solution of a metallic salt in order to form a guaiartrate. After thorough washing it may or may not be immersed in a very dilute solution of an aniline dye. After again drying the film is exposed and is then developed with a benzene developer. After drying the gelatine film is hardened by means of alum, chrome alum, tannic acid, &c., and the support is etched through the film by a suitable acid. If the image is etched on glass suitable pigments may be rubbed in and fixed.—C. H. B.

XXII.—EXPLOSIVES, MATCHES, Etc.

The Rate of Explosions in Gases. H. B. Dixon. Lecture Royal Inst., June 12, 1891.

See under II., page 752.

Modern Explosives in Relation to Health. Industries, August 21, 1891, 182.

IN compliance with the wish of the workpeople a committee was formed in September 1889 of the Durham Coal Owners' Association consisting of representatives of both masters and men, with two of Her Majesty's Inspectors of Mines, to consider the question and report whether the fumes produced by the combustion of *Tonite* and *Robarite* were injurious to health.

The medical report of Drummond and Hume shows that after thorough inquiry and examination, they could find no evidence of acute illness being caused. The general conclusions arrived at by the united experts, chemical and medical, were that (1) the fumes produced by *Tonite* and *Robarite* are not more dangerous than those from gunpowder. (2.) Nitrobenzene is apparently not produced by the combustion of *Robarite*. (3.) The carbon monoxide produced is only present in traces. (4.) An interval of five minutes should be allowed to elapse before the hewers re-enter the scene of firing; and (5) that as a portion of the gases in the fumes came from the fuse the charges should be fired by electricity.

Dynamite. V. Meyer. *Annalen*, 1891, 264, 127–129.

ACCORDING to the researches of Abel, explosive substances are not exploded by the detonation of any other body, but it is only certain detonators which produce an explosive effect in each case. For instance, large quantities of iodide of nitrogen will not explode gun-cotton, and dynamite is not fired by all explosives. Hence it appears that the explosive wave of the detonator must be specially suited to the explosive, and consequently one would expect that each explosive would be its own best detonator. The author observed, however, that in one instance, when he exploded a dynamite cartridge as a lecture experiment and had pushed an ordinary detonator further than usual into the mass

of the dynamite, that although an explosion took place, a considerable portion of the dynamite remained unaffected and was merely scattered about, a result which is quite out of accord with the above theoretical idea. In like manner, the author points out that Abel, on allowing a weight of 22 kilos. to fall through a space of 11.9 m. upon compressed gun-cotton, found that only a comparatively small portion of this material was exploded, whilst the greater portion was scattered about in a finely-divided state.

—C. A. K.

PATENTS.

Improvements Relating to Explosive Projectiles or Shells and to Cartridges or Charges for Use therein. J. M. McMahon, New York, U.S.A. Eng. Pat. 9612, June 20, 1890, 1s. 3d.

THE object of this invention is to enable nitro-glycerin and other high explosives to be fired with safety in shells. For description of the numerous means by which the inventor proposes to effect his purpose, the original specification, with its copious description and numerous drawings, must be consulted.—W. M.

Improvements in the Manufacture of Explosive Projectiles. A. Martin, Birmingham. Eng. Pat. 11,616, July 24, 1890, 6d.

THE object of the invention is to prevent the blowing out of the fuse and the consequent failure of the shell to burst under the force of the explosion. For this purpose "the base of the shell is formed by closing in or contracting the internally threaded rear end of the shell behind or around an externally threaded ring or bushing after the same has been screwed into the body of the shell. The ring or bushing is thus wholly or partially imprisoned by the contracted end of the shell, the fuse being screwed into a tapped hole passing through both the closed-in base of the shell and the internal ring or through the bushing only, as the case may be."—W. M.

Improvements Relating to the Manufacture of Explosives and to Apparatus therefor. H. H. Lake, London. From H. S. Maxim, Westminster. Eng. Pat. 15,183, September 30, 1890, 6d.

THE inventor proposes to effect great economy in the manufacture of nitrocellulose by dipping the cotton successively in acid baths of increasing degrees of strength. The excess of acid is removed at each operation from the cotton. When the acids in the final bath become too weak to properly complete the nitration, the weakest bath is removed and a fresh bath of highly concentrated acids is added which becomes the final one, and so on systematically.

After immersion in the last bath the cotton is left in contact with the adhering acids in closed chambers for some hours. It is then quenched in a large quantity of water and put into a pulping mill which is provided with heating coils, so that the wash water can be heated, and thus the material can be thoroughly washed without having recourse to the usual boiling.—W. M.

Improvements in Matches. F. A. Ventris, Reading. Eng. Pat. 4381, March 11, 1891, 3d.

THIS improvement consists in coating wooden splints with wax, stearin, or any other substance.—W. M.

Improvements in Smokeless Blasting Compounds and Cartridges made therefrom. A. Moschick and A. Brunngr. Graz, Austria. Eng. Pat. 5843, April 4, 1891, 6d.

THE blasting compound consists of a mixture of malt germs or cocons, ammonium nitrate, and potassium chlorate. The malt germs can be either desiccated or undessicated,

or can be used in a dried or in a steeped condition. The nitrate of ammonium and chlorate of potassium can be employed either solid or dissolved, or the materials for producing these salts can be so used as to be converted into the salts in the blasting material. Other indifferent materials can also be added to the mixture for colouring purposes, such as aniline dissolved in alcohol or glycerol. Further, either of the above salts may be omitted from the mixture, which can be prepared either wet, dry, warm or cold. By modifying the proportions of the ingredients any desired degree of explosive force can be attained. The cartridge is cylindrical, with a central boring for the introduction of the match, round which five air channels are arranged, whilst it also contains a recessed air-chamber at the base. A sketch is given. The name "Dynamoit" is proposed for the new explosive.—C. A. K.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

Brunton's Quartering Shovel. Eng. and Mining 1891, 718.

THE author has invented a rapid and accurate sampling tool. The tool consists essentially of a flat-bottomed, well-balanced steel shovel 10 in. in width, having vertical sides, and two central partitions $2\frac{1}{2}$ in. apart, thus dividing the shovel into three compartments, the centre one being closed by a curved back, and having a width one-quarter of the whole.

SAMPLING SHOVEL.

To use it the shovel is pushed into a pile of finely-crushed ore. As the shovel is raised it is drawn back at the same time with a sharp rotary motion to the right, which throws the ore contained in the outside compartments out from the back end of the shovel into a rejected ore pile. When the necessary throw to accomplish this result has been given, the motion is reversed and the shovel brought rapidly to the left, which action discharges the sample from the central compartment of the shovel upon a pile.

Tests at sampling works and different smelters upon hundreds of lots of ore, many of them in duplicate and triplicate, show that there is no difference between the results obtained by this method and Cornish quartering. Experienced operators attain such great rapidity in this method of quartering that it will doubtless be as applicable to concentrates and all other finely-crushed material as to the final reduction of machine samples. In some recent speed tests it was found that a ton of ore could be cut down to a 100-lb. grinder sample by one man in 15 minutes.

Apparatus for the Constant Generation of Gases.

R. I. Bricht and O. Foerster. Chem. Zeit. 1891, 15, 563.

THE authors are in the habit of drying feeding cakes, and their ethereal extracts, in a current of carbonic anhydride. As the Kipp's apparatus requires a good deal of attention, and wants often re-charging, they have now constructed an apparatus which will be found to answer better, and can be left for a long time to itself.

Fig. 1 represents the apparatus. A is a glass cylinder 1 metre in height and 10 cm. in diameter, filled with small

Fig. 1.

lumps of marble. The top of the cylinder is fitted with a treble-perforated ground glass stopper A' , and the lower part is connected with the tube b . Through the tube a (see Fig. 2)

Fig. 2.

A CONSTANT GENERATOR OF GASES.

which can be closed by the stop-cock, and the lower part of which is drawn out into four points, hydrochloric acid contained in the reservoir B is allowed to slowly drop on to the marble. Having to traverse such a long distance, the acid is almost completely spent before it reaches the bottom. The solution of the calcium chloride flows through the tube b into the flask C, which must contain sufficient fluid to prevent escape of gas. The tube must have a sufficiently large diameter so as never to be filled and consequently not to act as a syphon. The cylinder A is connected with the reservoir B by means of the tube β (Fig. 2), which in turn is connected air-tight with c by means of an india-rubber tube, in order that the pressure of the gas in both tubes shall be the same. The carbonic acid finally escapes through the tube γ (Fig. 2) and is passed through a wash-bottle. If the marble wants

replenishing, all the analyst has to do is to remove the stoppers a and c .

The same apparatus may of course also be used for generating other gases such as hydrogen sulphide.—L. de K.

Continuous Apparatus for the Generation of Chlorine.

G. Grünewald. Zeit. Chem. u. Phys. Unterr. 1890, 4, 84.

The flask A contains the manganese dioxide and is provided

Fig. 1.

APPARATUS FOR GENERATION OF CHLORINE.

with a rubber stopper having two holes through one of which the bent tube a, b, c, d , passes to the flask B, whilst a tube provided with a stop-cock is inserted in the other. By opening or closing this stop-cock the acid is drawn into or forced back from the flask A, the acid being contained in B and C. The bent tube a, b, c, d , must be capable of being moved up and down. To prevent the stopping up of the bent tube it is provided with a number of small holes at the bottom, and is surrounded by a wider tube also containing small holes at the sides as shown in Fig. 2. The dimensions

Fig. 2.

recommended are as follows:—Flask A, 300 cc.; flask B, 320 cc.; bulb C, 600 cc.; a, b , 24 cm.; b, c , 12 cm.; c, d , 12 cm.; l , 40 cm. For larger forms of apparatus these proportions should be adhered to. The apparatus can also be employed for the continuous generation of other gases that require heat for their production.—C. A. K.

Apparatus for the Rapid Determination of Carbon Dioxide in Furnace Gases.

Thonind. Zeit. 1891, 15, 539—540.

The apparatus, as shown in the Figure, consists of a vessel a having a capacity of 100 cc. and provided with an inlet and outlet tube. A graduated tube c , divided into cc., and fitted with a stop-cock, is ground into a at b . The stopper b is bored at the side, so that communication between the vessel a and its side tubes can be made or closed.

The vessel *a* is filled with the furnace gas to be tested by drawing it in through the tube *c* by means of the rubber ball *g* in the usual way. The graduated tube *e* is filled with caustic soda solution of specific gravity 1.25 to the mark *f*. A blank experiment is first made by filling the vessel *a* with air free from carbon dioxide, closing the openings of the side

APPARATUS FOR DETERMINING CARBONIC DIOXIDE.

tubes by turning the stopper *b* and opening the cock communicating with *c*. The liquid in *e* falls to a certain point, which is made the zero of the instrument. Correction for temperature and pressure is neglected, as the instrument is only intended for rough technical purposes.

In making a determination, the vessel *a* having been filled with the gas to be tested, the soda solution is allowed to flow in until absorption of carbon dioxide is complete and no more can enter. The volume of soda solution used then gives at once the percentage of carbon dioxide in the sample.

Determinations made by this instrument agree well with those made by more accurate apparatus.—B. B.

INORGANIC CHEMISTRY.— QUALITATIVE.

m-Phenylenediamine as a Reagent for Active Oxygen.
P. C. CARONNOY. Bull. Soc. Chim. 1891, 5, 855—857.

The author has made some experiments with *m*-phenylenediamine as a reagent for the detection of active oxygen, a use for which it has been recommended by Deniges (Bull. Soc. Chim. 1891, 5, 293). A 1 per cent. alcoholic solution of the hydrochloride of the base was prepared and mixed with a few drops of ammonium hydrate; such a solution, as Deniges has shown, gives a blue colouration when heated with hydrogen peroxide. The author finds that the active oxygen contained in animal black, resin black, coke, and mineral black (the residue of calcined schists), gives immediately an indigo blue colouration with the reagent; the reaction is less decided when these substances have been washed with hydrochloric acid. Platinum black acts still more powerfully, a milligramme of the same being sufficient to cause the colouration of 10 cc. of the reagent. Ozone gives a very distinct brown colouration, whilst ordinary oxygen, even under a pressure of 300 atmospheres, fails to effect any change.

As *m*-phenylenediamine thus distinguishes between ozone, hydrogen peroxide, and the active oxygen contained in charcoal, &c. (this Journal, 1890, 657), it is superior as a reagent for active oxygen to the methyl derivatives of *p*-phenylenediamine proposed by Wurster (this Journal, 1887, 361), which do not so discriminate.—F. B.

INORGANIC CHEMISTRY.— QUANTITATIVE.

Estimation of Bismuth in Silver Refinery Slags.
W. HAMPE. Chem. Zeit. 1891, 15, 410.

At Lautenthal crude silver is refined according to Roessler's method (this Journal, 1889, 286) by treating it in graphite crucibles with powdered quartz and silver sulphate, this process occasioning less loss of silver and purifying it almost completely from bismuth. The slag consists mainly of silicates, and is sold according to the percentage of silver and bismuth. For a complete analysis the slag is evaporated to dryness with nitric acid, taken up with nitric acid and water, filtered, and the residue fused with soda in a platinum crucible, the fused mass treated with nitric acid, the solution evaporated to dryness, &c. For a determination of the bismuth it is sufficient to digest 1 gm. of the finely-powdered slag with 15 cc. of the nitric acid for a considerable time, adding 10 cc. concentrated hydrofluoric acid, and when solution is complete adding a few drops of sulphuric acid and evaporating to dryness. The residue is dissolved in nitric acid, filtered from graphite, neutralised with ammonia, precipitated with ammonium carbonate, boiled, filtered, the precipitate dissolved in nitric acid, sulphuretted hydrogen passed in, the precipitated sulphides redissolved in nitric acid, treated with ammonium carbonate, the precipitated lead and bismuth carbonates dissolved in hydrochloric acid, evaporated almost to dryness, treated with excess of hot water, and the undissolved bismuth oxychloride filtered off, dissolved in nitric acid and reprecipitated with ammonium carbonate. The dry bismuth carbonate is removed as far as possible from the filter paper from which the adhering traces are dissolved off with nitric acid, the solution evaporated to dryness in a weighed porcelain crucible, the bulk of the carbonate added, and the whole ignited to oxide.

The following is an average analysis of a silver slag from the Roessler process:—

SiO₂, P₂O₅, SO₃, S, FeO, Al₂O₃, Bi₂O₃, PbO,
10.07, 0.61, 0.61, 15.13, 13.47, 0.43, 6.61, 33.50,

Ag₂O, Cu, Sb, CaO, MgO, K₂O, Na₂O,
2.05, 0.45, 0.02, 1.73, 0.25, 0.64, 0.26.

—S. B. A. A.

Estimation of Phosphorus in Pig Iron by the Centrifugal Process. C. REINHARDT. Chem. Zeit. 1891, 15, 410.

THE centrifugal process for estimating phosphorus in iron is now largely adopted in German steel works. Bormann and Von Reis (this Journal, 1890, 111) recently rendered it available for use with high carbon steels by introducing potassium permanganate into the boiling solution of steel. Von Reis has determined the influence on the volume of the separated precipitate of the amount of acid, ammonium nitrate, and molybdate present, and of the dilution, but has overlooked the effect of variations of temperature and of the time of rotation. The bulk of the precipitate is greater when the temperature of precipitation is high, and decreases with continued rotation, and in order to obtain satisfactory results the method of working must be absolutely uniform. The process is conducted by the author as follows:—Two grams of pig iron (1 to 0.5 gm. if there be over 1 per cent. of phosphorus) are treated in a 500 cc. flask with 60 cc. of nitric acid (sp. gr. = 1.2), heated until solution is complete and the nitrous acid is expelled, a solution of potassium permanganate (10 cc. for grey iron, 20 cc. for white iron, 30 cc. for spiegel and ferro-manganese) added a little at a time, the whole boiled for a few minutes longer and a solution of potassium oxalate added drop by drop until the liquid becomes clear. After boiling for a little while it is cooled, diluted to 250 cc., the silica (when there is much) allowed to subside, and filtered off; 25 cc. of the solution (0.2 gm. iron) are pipetted off into a 200 cc. Erlenmeyer flask, which must be previously cleaned by rinsing with 50 cc. of 10 per cent. ammonia, distilled water, 100 cc. of warm hydrochloric acid (1:1) and distilled water successively to prevent adhesion of the precipitate to the sides of the flask,

10 cc. of acid ammonium nitrate solution are added, the whole heated exactly to 70°, 10 cc. of ammonium molybdate solution added, and the mixture briskly agitated for 1 to 2 minutes and allowed to cool. The pear-shaped vessel with graduated stem in which the precipitate is rotated is cleaned first with a strong jet of distilled water, then, if necessary, with dilute ammonia and water, and finally it is half filled with hot hydrochloric acid (1:1), emptied and rinsed with distilled water. The precipitate is poured into this vessel directly, the last portions being washed in with water containing a little ammonium nitrate; the vessel is then closed with the thumb, well shaken and placed in the centrifugal machine. The latter is rotated for two minutes at the rate of 20 revolutions per second, and then violently brought to a full stop, the vessel removed, closed, tapped on the bench until the precipitate has a level surface, and the volume read off. The mean coefficient or value of a division of the calibrated stem of the vessel, must be ascertained by a number of very carefully made comparative gravimetric and centrifugal determinations. A series of analyses given by the author show a difference from 0.005 to 0.026 per cent. of phosphorus in different classes of iron.

The reagents used in the above process are as follows:—
(a.) *Acid ammonium nitrate*, a clear solution of 400 grms. of ammonium nitrate in 280 cc. of water, to which is added 280 cc. of nitric acid (sp. gr. = 1.4). (b.) *Potassium permanganate*, 28 grms. of the crystals are dissolved in 1 litre of water. (c.) *Potassium oxalate*, 250 grms. of the neutral salt in 1 litre of water. (d.) *Molybdate solution*, 180 grms. of molybdic acid are dissolved in 450 cc. of water and 450 cc. of 20 per cent. ammonia, the solution allowed to stand several days, filtered and 450 cc. of the filtrate added to 1 litre cold nitric acid (sp. gr. = 1.2), heated to 80° or 90° C., let stand for some days and filtered. (e.) *Wash-water containing ammonium nitrate*, a clear solution of 750 grms. of ammonium nitrate in 1 litre of water is added to a mixture of 250 cc. of nitric acid (sp. gr. = 1.4) with 3½ litres of water.—S. B. A. A.

Analysis of Phosphates. J. H. Vogel. Chem. Zeit. 1891, 15, 495—499.

For the estimation of ferric oxide and alumina the author prefers a combination of the methods of Glaser (this Journal, 1890, 111) and Stutzer, as follows:—The lime is precipitated as sulphate according to Glaser's method, and the filtrate is then rendered alkaline with excess of ammonia; this excess of ammonia is not expelled by boiling. The precipitated phosphates of iron, alumina, and possibly a little magnesia, are filtered off, and then, without any washing, 30 cc. of nitro-molybdate solution are poured on to the precipitate while still on the filter. The beaker, in which the phosphates were precipitated, and which will still contain a little of this adhering to the sides, is placed under the funnel, and the phosphates become dissolved by the nitric acid of the molybdic acid solution. 20 cc. of the molybdate solution are diluted to 100 cc. with water, and the filter thoroughly washed with it. The phosphoric acid in the solution is precipitated and filtered off, and the filtrate, which now contains the iron, alumina, and magnesia (if present at all) is heated to boiling, and after the ferric oxide and alumina are completely precipitated with ammonia, 10 cc. of concentrated ammonia are added. It sometimes happens that some molybdic acid precipitates with the iron and alumina, but this will be entirely redissolved by excess of ammonia. The magnesia present remains unprecipitated, and the precipitated iron and alumina are therefore pure.

The results obtained by the author are good.

If it be desired to estimate the magnesia also, it is recommended to allow the first ammonia precipitate, consisting of the phosphates of iron, alumina, and magnesia, to stand for 24 hours, instead of filtering it off while still hot. In this case the whole of the magnesia is separated with it, and will be found, together with the ammonium molybdate, in the filtrate, after separating the ferric oxide and alumina.

—J. W. L.

Estimation of Sulphur in Iron and Steel. G. Hattensaur. Chem. Zeit. 1891, 15, 521.

THE accuracy of the results obtained by dissolving the metal to be tested in hydrochloric acid and oxidising the sulphuretted hydrogen evolved has been questioned by Meineke (this Journal, 1888, 645) and others.

A series of analyses of Siemens-Martin metal made by the author by this method, and by dissolving the metal in a solution of sodium copper chloride, yielded, however, very concordant results, as is evident from the following figures:—

—	No. 1.	No. 2.	No. 3.	No. 4.	No. 5.	No. 6.	No. 7.
Solution in hydrochloric acid.	0.022	0.032	0.034	0.008	0.025	0.027	0.011
Solution in sodium copper chloride.	0.020	0.033	0.033	0.007	..	0.027	0.012

It may be noted that in one of these samples (No. 6) the whole of the sulphur was evolved on treatment with hydrochloric acid, in spite of the presence of a considerable quantity of copper (0.16 per cent.).—S. B. A. A.

The Employment of Iodic and Bromic Acids in Quantitative Analysis. A. Schwicker. Chem. Zeit. 1891, 15, 845—846.

THE author has independently elaborated a volumetric process similar to that of Feit and Kubierschky (this Journal, 1891, 486) for the estimation of reducing bodies, involving the use of iodic or bromic acid. The author's method differs from that of Feit and Kubierschky in so far that the bromine liberated by the reduction of the bromic acid is not boiled off prior to titration with sodium thiosulphate. Of course, in those cases when the substance being estimated is only completely oxidised at a boiling temperature, or when it is necessary to filter the liquid, only the latter process is permissible. Iodic acid is only capable of very limited application on account of its feeble oxidising power. Sulphurous acid is almost the only body that may be conveniently estimated by its means. The reactions on which the method is based are as follows:—

It appears, therefore, that it is only necessary to know the thiosulphate equivalent of the standard solution of iodic or bromic acid before and after the addition of the reducing body which it is desired to estimate. The difference between the two volumes of thiosulphate is a measure of the oxygen consumed by the reducing substance. The author employs normal-tenth and normal-hundredth solutions of sodium thiosulphate, potassium bromate, and potassium bi-iodate. In carrying out an analysis a measured volume of iodate or bromate solution is acidified with an excess of sulphuric acid, and a known quantity of the substance to be estimated is added. After a short time an excess of potassium iodide is added, and the liberated iodine is titrated with sodium thiosulphate. The following example will show the method of calculation:—

10 cc. of a solution of sodium sulphite, containing 0.01038 gm. of Na_2SO_3 , were treated with 10 cc. of normal-tenth iodate solution. Afterwards 8.35 cc. of normal-tenth thiosulphate were required to absorb the liberated iodine. The difference (10 cc. — 8.35 cc. = 1.65 cc.) represents the volume of iodate consumed. Now, 1 cc. of normal-tenth iodate equals 0.0063 gm. Na_2SO_3 . Therefore, 1.65 cc. = 0.01039 gm. Na_2SO_3 .

The other test analyses given are very satisfactory.

—H. T. P.

The Estimation of Carbon Dioxide. F. Tschaplowitz.
Zeits. Anal. Chem. 1891, 30, 279-282.

THE method here described relates to the estimation of carbon dioxide in carbonates, and is used by the author in cases where only a small quantity of material is available for examination. Schulze's method (Zeits. Anal. Chem. 9, 290), in which the carbonic acid evolved is absorbed by a solution of barium hydrate of known strength, and the excess of barium hydrate afterwards titrated with oxalic acid, using turmeric tincture and paper as indicator, he finds too tedious. Weighing in an absorption apparatus, the gain in weight indicating the carbon dioxide absorbed, he finds open to two objections that the aqueous vapour evolved during the boiling required to expel the carbon dioxide from the generating flask is not completely absorbed by such drying materials as sulphuric acid, calcium chloride and anhydrous copper sulphate, and if hydrochloric acid be used for evolving the carbon dioxide, some of this passes the copper sulphate absorption tube and is weighed as carbonic acid. He also finds that self-contained apparatus, in which the carbonic acid is determined by the loss in weight after its expulsion, are unreliable owing to the difficulty due to surface condensation, as these apparatus, owing to their irregular shape, cannot be easily perfectly cleaned or brought to the same condition of surface at the beginning and end of the experiment. To avoid these objectionable features he uses an absorption apparatus consisting of a double-necked flask, with corks in each neck, through which pass wide tubes. The tubes are filled with glass beads about the size of peas, and a layer of beads 4 cm. thick covers the bottom of the flask. About 25 cc. of a 1.5 per cent. caustic potash solution is poured over the beads. The carbonic acid is evolved by sulphuric acid in a flask which is attached to the absorption flask by an india-rubber tube. This generating flask should be large enough to contain sufficient water to dissolve any calcium sulphate that may be formed in it. After boiling to expel all the carbon dioxide from the generating flask, the beads are rinsed with hot water out of the tubes of the absorption flask into the bottom of this flask, and a solution of barium chloride is added, and after closing the necks of the flask it is allowed to stand two hours. The excess of caustic potash is then titrated with 1.20 normal oxalic acid, using turmeric tincture and paper as indicator. A blank titration with the caustic potash, using the same quantity of hot water and barium chloride, and allowing to stand two hours, must also be made.

—H. S. P.

A New Volumetric Method of Estimating Manganese.
L. Blum. Zeits. Anal. Chem. 1891, 30, 281-288.

THIS method depends upon the precipitation of manganese as manganese ammonium ferrocyanide, $Mn(NH_4)_2Fe(CN)_6$, by a standard solution of potassium ferrocyanide, from an ammoniacal solution of manganese containing ammonium chloride. When tartaric acid and a ferric salt are present in such a solution, the iron is not precipitated by potassium ferrocyanide, but after the whole of the manganese has been precipitated an excess of ferrocyanide is indicated by taking out a drop of the liquid upon a porcelain plate and mixing it with a drop of acetic acid; the ferric salt and the excess of ferrocyanide then react and produce the blue colour of iron ferrocyanide. The presence of any of the precipitated manganese ammonium ferrocyanide in the drop of liquid does not interfere with the test, as the manganese salt and the ferric salt do not react together in an acetic acid solution, even after a considerable time. Manganese ammonium ferrocyanide and acetic acid react and produce ammonium acetate and an acid manganese salt of ferrocyanic acid, viz., $MnH_2Fe(CN)_6$.

When much iron is present the yellow colour of the solution renders the finishing point of the titration indefinite. This is the case in testing steels for manganese by this method, but the author has obtained good results in testing manganese ores. In testing manganese ores 5 grms. of the sample are dissolved in concentrated hydrochloric acid, and the solution made up to 250 cc. without removing the insoluble residue. 50 cc. of this solution (equal to 1 gm.

of the sample) are then measured from a pipette into a beaker. If no iron or not enough iron be present, a few drops of ferric chloride are now added, then 20 cc. of a concentrated solution of ammonium chloride and 30 cc. of tartaric acid solution (1:2) are added, and finally the mixture is rendered strongly ammoniacal. It is then brought to the boiling point and titrated with a standard solution of potassium ferrocyanide, the strength of which has been accurately ascertained by standardising with a solution of pure manganese chloride of known strength. An excess of ferrocyanide solution is shown to be present when a drop of the liquid from the beaker placed upon a white porcelain plate gives a blue colour when mixed with a drop of concentrated acetic acid.

The author found that the potassium ferrocyanide supplied by manufacturers as pure, contained a considerable quantity of sodium ferrocyanide. If, therefore, the standard solution be made on the assumption that the potassium ferrocyanide is pure, results that are too low are obtained owing to the lower molecular weight of sodium ferrocyanide. The solution must therefore be standardised with a known quantity of manganese.

Ferrous salts and zinc salts when present in the manganese solution vitiate the accuracy of the test, as these salts are precipitated by potassium ferrocyanide. If ferrous salts are present they must therefore be oxidised by a few drops of nitric acid.

The standard solutions of potassium ferrocyanide used by the author was made by dissolving 38.487 grms. of crystallised potassium ferrocyanide in one litre of water. One cc. of this solution was found to be equal to 0.005532 gm. of manganese.—H. S. P.

Determination of Rhodium, Mercury, and Gold by Electrolysis. E. F. Smith. J. Anal. and Appl. Chem. 1891, 5, 200-201.

Rhodium.—The author used for his experiments a solution of crystallised rhodium-sodium chloride, 10 cc. of which contained 0.098 gm. of the metal. 10 cc. of this solution were mixed with 30 cc. of a solution of sodium phosphate (sp. gr. 1.0358), and 3 cc. of solution of phosphoric acid (sp. gr. 1.347). After diluting up to 180 cc., a current yielding 1.8 cc. of electrolytic gas per minute was applied. The precipitation of the metal took place at the ordinary temperature, and was finished in seven hours. 0.0982 gm. of rhodium was found. The liquid was at first of a dark purple colour, but became gradually colourless, a sign that the metal had completely precipitated. The metal which was deposited on a platinum dish was black, and adhered so strongly that it could readily be washed with boiling water without danger of loss.

Mercury.—The best plan is to prepare a solution of mercuric sulphide in sodium sulphide. The latter is best prepared as follows:—A solution of caustic soda of 1.3 sp. gr. is saturated with hydrogen sulphide. The same quantity of soda is then added, and the liquid once more treated for several hours with hydrogen sulphide. The liquid is then rapidly concentrated and allowed to crystallise in a closed flask. After recrystallising the product, it will be fit for use.

The author carried out several experiments with the same solution containing 0.1903 gm. of mercury. It was mixed with 20, 20, 20, 20, and 30 cc. respectively of the sodium sulphide solution (sp. gr. 1.19), diluted up to 125, 125, 125, and 130 cc., and exposed to a current yielding 1, 1, 1, 1.2, and 1.2 cc. of gas per minute respectively. After the current had been acting over night, the amounts of mercury precipitated were respectively 0.1902, 0.1905, 0.1907, 0.1910 and 0.1910 gm. The deposit was greyish and very compact. It was dried by gently blowing over it. The presence of arsenic does not interfere with the process.

Gold.—A solution of gold chloride containing 0.1446 gm. of metal was mixed with 10 cc. of the sodium sulphide solution, diluted with 100 cc. of water, and exposed all night to the action of a current yielding 2.6 cc. of gas per minute. The precipitated metal was bright yellow,

adhered very firmly, was washed with water, and dried on a warm iron plate. Its weight amounted to 0.1446 grm. In a second experiment the double quantity of sodium sulphide was used and the current allowed to act for 5½ hours. The gold which was deposited on platinum was completely recovered. It may be readily removed from the dish by a solution of potassium cyanide.

Gold may be separated in this manner from arsenic, molybdenum and tungsten, but not from antimony or tin.

—L. de K.

New Methods of Quantitative Analysis. A. Baumann.
Zeits. f. angew. Chem. 1891, **11**, 328—332.

THE author has already described various methods of analysis depending upon the fact that 116.29 parts by weight of chromic acid will liberate 63.84 parts by weight of oxygen from an acid solution of hydrogen dioxide. In the present paper he describes methods, based upon the same principle for estimating lead, bismuth, and barium. These substances all yield chromates insoluble in acetic acid. The precipitated chromate is washed and is then introduced into an apparatus for testing and measuring gases, where it is mixed with hydrogen peroxide and dilute acid. The volume of oxygen evolved is then measured, and from this measurement the quantity of lead, bismuth, or barium, as the case may be, is calculated. Or the base to be determined may be precipitated with a measured quantity of potassium bichromate or chromate solution of known strength, an excess being used. The solution is then made up to a certain bulk, and the precipitate filtered off through a dry filter paper. An aliquot part of the filtrate is then taken and the quantity of chromic acid in excess determined in it by agitating with hydrogen peroxide and measuring the oxygen evolved. In the case of barium a solution of ammonium chromate is employed.—H. S. P.

ORGANIC CHEMISTRY.—QUALITATIVE.

Reaction for Cocaine. F. Flückiger. Pharm. Zeit. 1891, **36**, 72.

THE author confirms Schell's reaction for cocaine hydrochloride with moistened calomel, which latter is reduced, and shows further that cocaine itself behaves exactly similarly, despite Schell's statement to the contrary, when the two substances are boiled with water. When alcohol is substituted for water the reduction occurs in the case of the hydrochloride, but not with the free base.—C. A. K.

The Examination of Phenacetin by Means of Chloral Hydrate. L. Reuter. Pharm. Zeit. 1891, **36**, 185.

2.5 GRMS. of chloral hydrate are melted in a test-tube on the water-bath, and 0.5 grm. of the phenacetin to be tested is added. If the phenacetin be pure it will dissolve, forming a colourless solution, which only after prolonged digestion acquires a pink tint. But if the sample contain only a trace of *p*-phenetidin, the mixture will at once assume an intense violet to reddish or bluish-violet colour according to the amount of the impurity present.—H. T. P.

Some New Tests to Distinguish between Naphthalene and α - or β -Naphthol. L. Reuter. Pharm. Zeit. 1891, **36**, 289.

THE author adds 0.1 grm. of any of these compounds to 2.5 grms. of fused chloral hydrate and warms for 10 minutes. In some of these experiments he also added hydrochloric acid, with or without zinc.

		0.1 Grm. Naphthalene.	0.1 Grm. α -Naphthol.	0.1 Grm. β -Naphthol.
1	+ 2.5 grms. chloral hydrate	Colourless	Intensely ruby-red, transparent, not fluorescent.	Pure blue, transparent, not fluorescent.
2	Ditto + 5 drops of acid.....	Very slight pink	Intensely dark greenish-blue, not transparent.	Intensely yellow, transparent.
3	Ditto, with a piece of zinc..	Violet, passing into brown.	Colour changes to a dark violet-blue. (Water gives a violet flocculent precipitate.) Alcoholic solution, reddish-violet with a violet fluorescence.	Colour becomes of a deep dark brown. (Water throws down a greasy body.) Alcoholic solution, yellow with a blue fluorescence.

—L. de K.

A New Test for Resorcinols. L. Reuter. Pharm. Zeit. 1891, **36**, 292.

IF 0.1 grm. of resorcinol is dissolved in 50 cc. of potash ley and a little of this solution is heated in a test tube (placed in hot water) with addition of a drop of chloroform or bromoform, or with a little crystal of either chloralhydrate or bromalhydrate, the mixture quickly assumes an intensive ruby-red colour. The reaction is so delicate that even 1 part of resorcinol dissolved in 17,000 parts of potash ley will still show a distinct reddish colouration. (See following abstract).—L. de K.

Reaction for Resorcinol. L. Scholvién. Pharm. Zeit. 1891, **36**, 299.

THE author calls attention to the fact that the reaction described as new by Reuter (preceding abstract), has been known since 1872, when it was published by Guareschi.

—J. B.

Honey Testing. E. Dieterich. Helffenberger Annalen, 1890, 50.

HAENLE has submitted to dialysis, left- and right-handed honeys, also samples adulterated with starch syrup, and found that the genuine samples showed after 16—18 hours no polarisation, but the adulterated ones gave a fairly constant right-handed polarisation. Haenle therefore concluded that a sample of honey which after dialysis is right-handed may be taken to be adulterated with starch-syrup. In the author's laboratory these experiments were repeated. The samples were dissolved in 2 parts of water, and after being decolorised with animal charcoal, polarised. They were now submitted to dialysis, the outside water being constantly renewed. After respectively 10, 20, 30, and 45 hours dialysis, the liquid was evaporated to its original bulk and again polarised. The figures obtained show that prolonged dialysis may cause a right-handed polarisation even with pure samples, although there will of course be an interval when the polarisation will be *nil*.

—L. de K.

Testing Olive Oil. E. Dieterich. *Helffenberger Annalen*, 1891, 79.

Dress modifies Labiche's process for the detection of cotton-seed oil in olive oil as follows:—10 cc. of the oil are shaken in a test tube with 10 cc. of ether. 5 cc. of strong *liquor plumbi* are added, and finally, 5 cc. of ammonia, and the whole well shaken. In presence of Cotton-seed oil an orange-red colour gradually appears and may be more particularly noticed in the top layer. In the author's laboratory this test was tried with various oils with the following results:—Poppy oil, Nut oil, and Cotton-seed oil, all gave similar colours. Codliver oil, Arachis oil, Sunflower oil, Sesame oil, and Olive oil, were next examined and gave colours varying from orange to yellow, the colour being most intense in the codliver oil. Lard oil and Castor oil remained colourless. The test therefore fails to serve for the proper identification of cotton-seed oil, all the more because olive oil itself assumes a yellow colour. The test loses still more of its value when it is remembered that there are samples of Cotton-seed oil which do not give the reaction at all.—L. de K.

The Elaidine Test for Fatty Oils. C. Wellemann. *Landw. Versuchst.* 1891, 37, 447.

The author applied the elaidine test to olive oil and ground nut oil. 10 grms. of the oil were shaken in a test tube with 5 grms. of nitric acid of 1.37 sp. gr. (at 19° C.), and 1 gm. of mercury for three minutes. After standing for 20 minutes it was once more violently agitated for one minute. After this the time was noticed which the oil took to solidify. It then appeared that the temperature was of great influence on the result, a lower temperature assisting the solidification. Temperature is also of influence on the colour the mixture assumes. The manner of shaking the mixture is also of great importance, the more violently the mass is agitated at first, the more quickly it will set.—L. de K.

Testing Glycerin. J. Lüthke. *Apoth. Zeit.* 1891, 6, 263.

The value of the test for the purity of glycerin prescribed by the German Pharmacopœia, consisting in warming the liquid with an ammoniacal solution of silver nitrate (this *Journal*, 1891, 187) was recently disputed (*Chem. Zeit.* 14, 346), and the author's present results justify that condemnation. Of 21 samples tested, the whole number gave a colouration on heating to boiling. Small quantities of arsenic cannot be detected, although that is one of the objects of the test. Similarly nerolein and aldehydic substances are overlooked. The test recommended by the author for acrolein in glycerin consists in heating 5 cc. of the sample with an equal bulk of rosaniline bisulphite solution containing 1 gm. of the dye, 10 grms. of sodium bisulphate, and 15 grms. of 25 per cent. hydrochloric acid made up to 1 litre.—B. B.

On the Testing of Oil of Turpentine. G. Vulpinus. *Apoth. Zeit.* 1891, 6, 289.

The author finds that reliable determinations of petroleum in turpentine oil may be made by the following modification of a method proposed by Hinsdale. 1 gm. of the sample and 1 gm. of a pure oil of turpentine are weighed on separate watch glasses, which are then floated on a basin of water maintained at about 80° C. As soon as the pure turpentine has evaporated both watch glasses are weighed. The weight of the residue from the pure oil of turpentine (small quantity of resin always present in pure turpentine) is deducted from that of the residue in the watch glass which held the sample. The difference is petroleum, which may thus be determined to one-tenth of a per cent.—G. H. B.

Detection of Rosin Oil in Oil of Turpentine. E. Baudin. *J. Pharm. Chim.* 1891, 23, 279.

A drop of the oil to be examined is placed on the lower edge of a small piece of unglazed paper, such as cigarette paper, and there allowed to evaporate spontaneously. If the oil be pure no appreciable mark will remain on the paper, but if the sample contain rosin oil an oily spot is left behind. In doubtful cases 20–30 drops of the suspected oil are evaporated down to 6–8 drops in a small porcelain dish, and the residue is then tested as above.—C. A. K.

Sulphocarbazole as a Reagent for Distilled Waters.

L. Viron. *J. Pharm. Chim.* 1891, 23, 441.

The reagent employed to characterise such distilled waters as Cinnamon water, Cherry laurel water, Orange blossom water, &c., consists of a mixture of 0.15 gm. of sulphocarbazole and 100 cc. of pure sulphuric acid, which should be boiled for a few minutes to remove traces of nitrous acid. To make a test, 3 cc. of the yellowish fluorescent liquid are placed in a test tube and the water to be tested added gradually by means of a pipette until precipitation takes place. 3 cc. are generally required. Cinnamon water gives a brilliant red colouration, and then a rust-red precipitate; Cherry laurel water also first gives a red colouration followed by a brownish precipitate changing to dark blue; Orange blossom water gives a flesh coloured precipitate, the upper portion of which is of a chestnut brown colour. Peppermint water, Rose water, Ysop water, Melilot water, and Lime blossom water give more or less whitish precipitates which darken on exposure to the air. These tests serve not only to characterise the various waters, but also to detect any change they undergo.—C. A. K.

On Payen's Process for the Detection of Free Mineral Acids in Vinegar. F. Corcil. *Jour. Pharm. Chim.* 1891, 23, 444.

According to Payen's process 100 cc. of the suspected sample are boiled for 20 or 30 minutes with 0.05 gm. of potato starch. If no mineral acids were present the starch will have been but little inverted, and will consequently show with the iodine test; but the presence of even two parts per thousand of sulphuric acid is said to be sufficient to convert all the starch into dextrin or glucose. The author, however, cannot recommend the process as he still obtained the starch reaction with vinegar containing from four parts of sulphuric, or five parts of either hydrochloric or nitric acid per thousand.—L. de K.

Detection of Phenerythrene in Phenol that has turned Red. E. Fabini. *Pharm. Post.* 1891, 24, 185.

10–12 cc. of strong sulphuric acid are treated in a test tube with double the volume of the phenol. An orange-coloured zone is formed at the junction of the two liquids, above which a more or less violet-blue zone appears, the latter being characteristic of phenerythrene (this *Journal*, 153–154).—C. A. K.

Method of Detection of Sugared Wine in Natural White Wines. Sochaczewski. *L'Union pharm.* 1891, 32, 209.

ORGANIC CHEMISTRY—QUANTITATIVE.

Estimation of Free Acids in Butter. C. Hesana. *Chem. Zeit.* 1891, 15, 410.

The author has found that the volumetric estimation of the total free acids in butter only yields comparable results when the process is always conducted in exactly the same

way, even in the smallest particulars. He proceeds as follows:—

20 grms. of butter are melted on the water-bath, separated from the buttermilk, filtered, and 10 grms. of the liquid fat weighed out into a cylinder of about 40 cc. capacity 17—18 mm. in diameter, provided with a well-fitting ground stopper. The butter is then warmed up by dropping the cylinder into a water-bath, when 15 cc. of 95 per cent. alcohol are added, the whole warmed as before for a few minutes, shaken energetically for one minute and left in the water-bath until the alcohol separates from the oily layer. The latter is decanted into an Erlenmeyer flask and treated twice in the same way with successive quantities of 15 cc. of alcohol. The alcoholic solution, which contains the whole of the free acids, is titrated with decinormal soda in presence of 0.5 cc. phenolphthalein.

The author, like Schweissinger and others, has found that the rancidity of butter is entirely independent of the amount of free acid present, extremely rancid butter having often a low degree of acidity and vice versa.—S. B. A. A.

Determination of Ash in the Products of the Sugar Manufacture. E. Donath and G. Hattensaur. Chem. Zeit. 1891, 15, 520.

See under XVI., page 781.

Röse's Method for the Estimation of Alcohol. L. Grünhut. Chem. Zeit. 15, 847—848.

Röse's method for the estimation of alcohol is based on the idea that under certain conditions alcohol is completely oxidised to carbonic acid by potassium permanganate, according to the following equation:—

The author has had occasion to try the method and has followed Röse's instructions to the letter; but the results obtained were exceedingly unsatisfactory, the alcohol being found in all cases far too low. The discrepancies were discovered to be due to incomplete oxidation of the alcohol, the smell of acetic acid being plainly perceptible in several of the experiments. In fact by decreasing the volume of sulphuric acid employed with the permanganate the results agreed roughly with the hypothesis that the alcohol was oxidized to acetic acid. On the other hand, when the sul-

phuric acid was largely increased the alcohol found was also higher, but still unsatisfactory. In one case 200 cc. of strong sulphuric acid were used (50 cc. of permanganate, 2 cc. of dilute alcohol, and 3 cc. of water), the result obtained was 0.0509 grm. of alcohol, against the theoretical amount of 0.0585 grm. That Röse obtained satisfactory results by this process may possibly be due to the fact that he used absolutely pure alcohol in his experiments, whilst the author employed a more or less impure distillate from a fermented liquid. Still, under the circumstances, the author considers the method to be practically of very little use.—H. T. P.

On the Quality of various Lards. C. Engler and G. Rupp. Zeits. f. angew. Chem. 1891, 389—391.

The authors find that more than one half of the American lard consumed in Germany is either adulterated with cotton-seed oil or consists of a mixture of tallow, vegetable oil, and perhaps a small percentage of lard.

With a view to investigate the influence which the mode of feeding or different breeds of swine might exert on the composition of lard, the authors have collected and examined a number of samples of pure lard from different countries. The following methods of examination were adopted:—

1. Hübl's iodine absorption. This method gave the best results for deciding the quantitative composition.

2. Beechi's test of boiling with an alcoholic solution of silver nitrate. This was found very useful for qualitative information.

3. Labiche's colour test of treating with acetate of lead and ammonia. This test was not always found to be reliable, since it seemed much influenced by the action of light, also by the age and the rancidity of the sample.

4. Maumené's test of observing the increase in temperature on mixing with concentrated sulphuric acid. This gave satisfactory results when applied with care.

A useful reagent for indicating qualitatively the presence of vegetable oil in lard was found by Welmans in phosphomolybdate of soda dissolved in nitric acid. A solution of lard in chloroform shaken up with Welmans' reagent does not alter in colour when pure; the solution becomes green in presence of vegetable oil, increasing in intensity of colour with the quantity of oil. The green changes to blue on supersaturation with ammonia, whilst the solution of pure lard is not effected by excess of ammonia.

The table shows the results obtained by the authors on examination of a number of lard samples:—

Lard from	Hübl's Iodine Number.	Beechi's Silver Nitrate Test.	Silver Nitrate Test in Ethereal Solution.	Labiche's Lead Acetate Test.	Maumené's Reaction. Rise of Temperature.

Some Experiments on the Changes in Weight which Fatty Oils undergo on Exposure to Air. R. Kissling. *Zeits. f. angew. Chem.* 1891, 395—398.

See under XII., page 778.

On the Determination of Glycerol by Benedikt and Zsigmondy's Method. C. Mangold. *Zeits. f. angew. Chem.* 1891, 400—401.

THE author has simplified Benedikt and Zsigmondy's method (this *Journal*, 1889, 6) of determining glycerol as follows:—

To 0.2—0.4 gram. of glycerin dissolved in 300 cc. water containing 10 grms. of caustic potash, as much of a solution containing 5 per cent. potassium permanganate is added as will correspond to $1\frac{1}{2}$ times the theoretical quantity of glycerol (for one part of glycerol 6.87 parts of potassium permanganate). The operation is conducted in the cold and the solution must be agitated on addition of the permanganate. After standing for about half an hour at the ordinary temperature, sufficient hydrogen peroxide is added to completely decolourise the liquid; no large excess of peroxide should be used. The whole is now made up to 1,000 cc., well shaken, and 500 cc. filtered through a dry filter. After heating the filtrate for half an hour to destroy all hydrogen peroxide, and cooling to about 60° C., sulphuric acid is added, and the liquor titrated with permanganate.

Heating after the addition of permanganate is superfluous. The presence of butyric acid does not affect the result, since butyric acid does not become oxidised in the cold by an alkaline solution of permanganate; butyric acid yields oxalic acid only when boiled for a considerable time with an excess of alkali and potassium permanganate. Repeated determinations show that even the original method of Benedikt and Zsigmondy in the presence of butyric acid does not yield an appreciable increase of oxalic acid. A number of results of analysis by the above method are given by the author which prove the method of determination to be accurate even in presence of 90 per cent. of butyric acid.—K. E. M.

A New Method for the Valuation of Lubricating Oils. J. Lew. *Dingl. Polyt. J.* 1891, 280, 16—19 and 40—44.

See under XII., page 777.

On an Important Source of Error in the Gravimetric Estimation of Tannins. R. Koch. *Dingl. Polyt. J.* 280, 141—144 and 159—162.

THE author fully agrees with the conclusions arrived at by v. Schroder (*Dingl. Polyt. J.* 269, 38 and 82; this *Journal*, 1888, 647) with regard to possible errors in tannin estimations by the gravimetric method. He finds, however, that a still more important error is liable to creep into the results owing to the varying capacity of different samples of hide-powder for absorbing tannin, and especially the different colouring matters present in the material under examination. To be suitable for this process the hide-powder should be in a fine state of division, and have a woolly appearance; its colour should be white or yellowish-white, not grey, even when it is washed with water, pressed, and dried, and the cakes so obtained must retain their porous and friable nature. On extracting 7 grms. of the powder with 100 cc. of water, not more than 0.016 to 0.018 gram. of soluble matter should be found upon evaporating 50 cc. of the filtrate, as otherwise it is probable that owing to carelessness in the manufacture, so much decomposition of the skin will have occurred that its action will be abnormal. The smell is also important, and if it gives evidence of decomposition, the sample should be rejected. For the preparation of a hide-powder answering to these requirements, only the best fresh skins unbaired by lime should be employed, and the lime should be removed by as rapid washing as possible, the water being quite cold, and the purification being assisted by mechanical means. The drying should be hastened by removing by pressure as much water as possible, and should take place at ordinary temperatures in a well-ventilated room.

To show the large differences in the results caused by the employment of different samples of hide-powder, the author made a large number of tannin estimations on different materials. The first sample of hide-powder (I.) employed was obtained from Tharand. It gave rather too much (0.020 gram.) soluble matter on extraction (*ut supra*), and was rather too powdery in appearance, its smell also was

suggestive of decomposition. After washing with water several times, the soluble matter was reduced to 0.005 gram. Powder II. was prepared by the author in the manner previously indicated, and it may be regarded as a standard. After washing, it gave 0.001–0.005 gram. of soluble matter. Powder III. was an ordinary commercial sample, having a greyish colour and on moistening with water a very putrid smell. The soluble matter amounted to 0.129 gram. Powder IV. from the same maker contained only 0.018 gram. of soluble substances. On washing with water, the fibres cohered strongly together, had a very dark colour, and also a somewhat of objectionable smell; which properties are probably due to the skins having been unhaird by “sweating” instead of by lime. Powder V. was prepared from II. by washing in 70 per cent. alcohol instead of water; it differed in appearance but little from the original, but was found to be wetted again with difficulty, hence the employment of this method of purification is not to be recommended. Powder VI. was obtained from König and closely resembled I.; and Powder VII. was prepared by Trommsdorf. Powder VIII. was a sample from Schuchardt, having a dark grey colour and rather strong smell and yielding on extraction 0.058 gram. of soluble matter. By washing, however, it was found to yield a product of first-rate quality, a peculiarity which is due to its being prepared from skin other than that of the ox. Before powdering this hide had a thickness only of about 1.5 mm., hence the drying took place much more quickly than usual, not allowing time for decomposition to occur.

The varying nature of these different samples of hide-powder was readily shown by treating on hide-filters Nos. 1, II., IV., and V. with a 2 per cent. extract of fir bark. After standing half an hour the solution was gradually run off, and was found to possess in each case a different colour. That from IV. was water-white; I. yellowish; II. yellow-brown; and V. rather dark. A second quantity of solution was then passed through the hide, when the filtrates showed similar appearances. On examining the powders, IV. was found to be coloured very deeply for half the length of the column; I. for about two-thirds, and II. almost the whole amount; while V. was much lighter in appearance, but the colouration extended through the whole length.

In the analyses, from which the accompanying table is derived, the amount of tannin found in Powder II. is taken as the standard and the difference between it and that given by the other samples indicated; those figures marked with an asterisk being obtained by difference from the estimation of the “non-tannins” according to v. Schröder’s method (*loc. cit.*)—F. H. L.

Separation of Rosin from Fatty Acids. E. Twitcheell. Journal Analyt. and Appl. Chem. 1891.

By saturating a solution of fatty acids in absolute alcohol with gaseous hydrochloric acid the ethyl ethers of fatty acids are formed. By treating resin acids in a similar manner it was found that no combination took place when the solution was kept cool, and the resin acid could be subsequently separated by dilution with water and boiling to collect the precipitate.

The method of analysis depends upon the fact that in the reactions specified all fatty acids combine to form ethers neutral in alcoholic solution and unacted on by alkalis in the cold, while the rosin is left intact. The rosin reacts acid in alcoholic solution with phenolphthalein and unites readily with caustic potash to form a soluble soap. All that is necessary therefore is, by the means indicated, to combine the fatty acids with alcohol, when the resin acids may be titrated with standard caustic soda solution, using phenolphthalein as indicator, or they may be combined with potash, and the rosin soap thus formed separated from the unsaponified fatty ethers by extracting with naphtha in a separating funnel.

The gravimetric method is carried out as follows: 2 or 3 grms. of the mixture of fatty acid and rosin are dissolved in 10 times their volume of absolute alcohol in a flask, and dry hydrochloric acid passed through in a moderate stream. The flask is set in a vessel with water to keep it cool. The acid is rapidly absorbed, and, after about 45 minutes, the ethers separate, floating on the solution, and no more hydrochloric acid is absorbed. The flask is then removed and allowed to stand half an hour longer to ensure a complete combination of the alcohol and fatty acid. It is next diluted with about five times its volume of water and boiled until the acid solution is clear, the ethers, with rosin in solution, floating on the top. To this is added some naphtha and the whole transferred to a separating funnel, the flask being washed out with naphtha. The acid solution is then run off and the naphtha solution (which ought to measure about 50 cc.) washed once with water and then treated in the funnel with a solution of 0.5 gram. KOH and 5 cc. alcohol in 50 cc. water and agitated. The rosin is immediately saponified and the two layers separate completely. The solution of rosin soap can then be run off, treated with acid, the rosin collected in any manner desired, dried, and weighed. A second washing of the soap with naphtha is hardly necessary, as very little remains after the first extraction. The naphtha used is “74 gasoline,” and for this purpose is to be preferred to ether.

The first stages of the volumetric method are similar to those of the gravimetric, with the exception that the contents of the flask are washed into the separating funnel with ether instead of naphtha, and the ether solution in the funnel is then thoroughly washed with water, until the wash-water is no longer acid; 50 cc. of alcohol, previously neutralised, are then added and the solution titrated with standard caustic soda solution. If the combining equivalent of rosin be known, its percentage may be calculated, or some of the original mixture may be also titrated, when the difference in caustic soda required will correspond to the fatty acids converted into ether.

The author has tested this method by a number of experiments, some of which are described. The following experiments show the action of gaseous hydrochloric acid on alcoholic solutions of fatty and resin acids.

(1.) Five grms. of distilled fatty acids were dissolved in 50 cc. absolute alcohol, treated with gaseous hydrochloric acid in the manner described, then treated with water, boiled, washed in a separating funnel, and dried. They yielded 5.451 grms. of ethyl ethers. These ethers were dissolved in neutralised alcohol and titrated with a normal

solution of caustic soda. They required for neutralisation 0.14 cc. of the solution. This would represent 0.97 per cent. of resin acid, taking 346 as the combining equivalent of rosin, i.e., the weight of rosin neutralised by 1 cc. of normal alkali = 0.346 grm.

(2.) Five grms. fatty acids from a low grade tallow were treated in the same way, and required 0.06 cc. for neutralisation = 0.41 per cent. rosin.

These figures, although not indicating a perfect combination, are still very small, and can be explained, especially in the first case, by the supposition that there were actually some resin acids present, natural constituents of the crude fats.

On attempting to use alcohol of 90 per cent. instead of the absolute, the author only succeeded in etherifying 92 per cent. of the fatty acids.

(3.) Five grms. of an average sample of rosin were treated in exactly the same manner as in working with the fatty acids. After diluting with water and boiling, the rosin was collected by dissolving in a little ether and found to weigh 4.9382 grms. This was dissolved in alcohol and required 14.27 cc. of the caustic soda solution to neutralise it. Five grms. of the original rosin were titrated and required 14.45 cc. There had been a slight loss in drying, but no change in the combining weight.

When the alcoholic solution became heated by the passage of the hydrochloric acid or when the solution was boiled without first diluting with water, the rosin suffered some change and required less caustic soda to neutralise it.

Analyses were made of a number of mixtures. In using the volumetric method the mean combining weight of fatty acids was taken at 275, and of rosin 346.

A mixture consisting of 20 per cent. rosin, 80 per cent. fatty acid gave, by the volumetric method, 20.36 per cent., 21.40 per cent., and 19.91 per cent. of rosin. The same by the gravimetric method: 18.93 per cent. of rosin.

A sample of soap said to be made of 100 parts of fat to 40 of rosin, and therefore containing 28.67 per cent. of rosin, assayed by the volumetric method, 73.7 per cent. of fatty acid, and by the gravimetric method, 25.7 per cent. of rosin.

Unsaponifiable matter in the fat does not affect the process, but can be determined by the volumetric method in one operation, as follows: Two grms. of the original fatty mixture are titrated with normal caustic soda solution and saturate *a* cc. Two grms. are treated with hydrochloric acid &c., then filtered and are found to saturate *b* cc. Then

$$b \times 0.346 = \text{weight of rosin.}$$

$$a - b \times 0.275 = \text{weight of fatty acid.}$$

The remainder is unsaponifiable matter.

A mixture of rosin, fatty acid, and paraffin was prepared and analysed in this manner, with the following results:—

—	Calculated.	Found.
Rosin.....	21.3	22.6
Fatty acid.....	43.6	42.7
Paraffin.....	35.1	34.7

The author has since analysed a number of samples of soaps and always obtained the resins distinctly brittle and therefore practically free from fat. This he found to be the case even when the percentage of rosin was so low as 4 or 5 per cent.

In his experiments the caustic soda solution was normal, but a more dilute solution might be used with advantage, as a smaller sample could be taken and the operation considerably hastened.

The figures given have been those actually obtained, without correction for error, such as unsaponifiable matter in the original rosin, which would affect the gravimetric determination. The volumetric method he would prefer in all cases except where an examination of the rosin was desired.

ANALYTICAL AND SCIENTIFIC NOTES.

On the Influence of Climate on the Amount of Nicotine in Tobacco. A. Mayer. Landw. Versuchst. 1891, 37, 453.

ACCORDING to the author's investigations a liberal amount of heat and light, together with a sufficient moisture in a rich soil, will not only cause a luxurious development of the plants, but a large increase in the percentage of nicotine. The other organic constituents of the tobacco plant are not so much affected by climatic conditions.

—L. de K.

Hypiodons Acid. A. Schwieker. Chem. Zeit. 1891, 15, 630.

THE following fact affords evidence in favour of the existence of hypiodons acid. When urea is added to a freshly prepared solution of iodine in concentrated sodium hydroxide a brisk evolution of nitrogen commences; the same reaction proceeds even better when iodine is added to a solution of urea in sodium hydroxide. It is thus analogous to the action of sodium hypobromite on urea, and the presence in the above solution of sodium hypiodite, whose existence has already been foreshadowed by the observations of Schönheim and of Berthelot, is rendered probable.—A. R. L.

Trade Report.

(From the Board of Trade and other Journals.)

TARIFF CHANGES AND CUSTOMS REGULATIONS.

SWITZERLAND.

Classification of Articles in Customs Tariff.

Note.—Quintal = 220.4 lb. avoirdupois. Franc = 9 $\frac{1}{10}$ d.

The following decisions affecting the classification of articles in the Swiss Customs tariff were given by the Swiss Customs authorities in the month of July last:—

Zinc ashes, zinc scorie (waste from the manufacture of zinc powder, composed from metallic zinc and impurities).—Category 1. Free of duty.

Agalithe (asbestine, silicate of magnesia, used in paper factories as a substitute for kaolin or china clay); hydrated alumina in powder, calcined, &c., used as a substitute for kaolin in the manufacture of paper.—Category 160. Free of duty.

Gypsum paste.—Category 167. Duty, 20 cents. per quintal.

UNITED STATES.

Customs Decisions.

The following decisions respecting the construction to be given to Acts of Congress relating to the classification of articles in the Customs tariff, and the application of the Customs laws of the United States, have recently been given by the Customs authorities in that country:—

Ammoniacal cochineal is dutiable at 25 per cent. *ad valorem* under the provision for colours.

Grecian red, a colour composed of barytes 98 per cent. and aniline colour 2 per cent., is dutiable at 25 per cent. under paragraph 61 as a colour not specially provided for.

Prussiate of soda, a chemical salt composed of a certain percentage of carbon, nitrogen, iron, and sodium when in the dry state, and when crystallised of the same elements with about 41½ per cent. of water in addition, is dutiable under the provisions of paragraph 92 of Act of 1883, which levies a duty of 25 per cent. *ad valorem* on "all chemical

compounds and salts, by whatever name known," not specially enumerated or provided for in said Act.

Certain so-called "cocoa butterine" is dutiable at 25 per cent. under paragraph 76, N. T., as an expressed oil.

Cineine hydrobromate crystals, cineine hydrobromate powder, and cineine hydrochlorate crystals, which are salts crystallised from an extract of the fruit of the henlock plant, used exclusively as medicines, are dutiable at 50 cents a pound under paragraph 74.

EXTRACTS FROM DIPLOMATIC AND CONSULAR REPORTS.

FRANCE.

Olive Oil.

In discussing some of the injurious effects of the Franco-Italian tariff war the British Consul at Nice makes some interesting observations on the "olive oil question." Encouraged by the low import duty formerly exacted on the olive oils of Italy, some 30 or 40 firms were gradually established in Nice, which did large business in mixing the finest Nice oils with the more fruity Neapolitan variety from Bari, and then exporting the whole as Nice oil. To such an extent was this practice carried that about three times as much oil was annually exported from Nice as was produced in the entire territory. It is stated in defence of this practice of *coupage* that the flavour acquired by the oil rendered it more acceptable to northern palates, and considerable skill was exercised in the proper manipulation of the oil previous to placing it on the French or foreign markets, and there appears to have been no secrecy as to this manipulation. The duty on Italian olive oils has, however, been raised of late to 15 frs. the 100 kilos., or, in other words, has been quadrupled; and it is anticipated that the large oil trade which has become the principal source of export from Nice will be ruined by the new duty as soon as the stocks previously laid in are exhausted. It is said that the Tunis and Algerian oils are so inferior as to afford no proper substitute for the South Italian variety used in the *coupage*. It is felt that if any raw materials are to be exempt from the new exorbitant duties it should be the Bari oil, as being the raw material of the most profitable industry that has grown up in Nice. The new duty has already caused adulteration of a totally different form from that above described, and an ingenious process has been invented at the Station Agronomique de Nice by M. Brüllé, by which it has been discovered that Nice oil is now mixed to a large extent with cotton-seed oil and other grain oils, being subsequently re-exported as pure Nice olive oil. This process consists in the mixture of nitrate of silver and alcohol with the oil, which is subsequently boiled and changes colour, becoming reddish or brown, instead of retaining the greenish gold of the pure olive oil.

NORWAY.

Iodine.

A new industry, which promises to become of permanent value to the coast inhabitants of Jænderen, has recently been started in Norway. This is the burning of seaweed, which is found in great abundance on the coast, and the preparation of kelp for the manufacture of iodine.

SIAM.

Benzoin.

Benzoin is brought by traders from Luang Phrabang to Chiengmai, whence it is sent down to Bangkok. Some is sent to Bangkok via Korat, but that route is so infested with thieves that traders prefer to bring their gum to Chiengmai. A "hek Chin" (son of a Chinese father by a Siamese mother) is the principal benzoin buyer in Bangkok. According to him 9,386 $\frac{1}{2}$ lb. were brought to market in 1890. There are two qualities; the best kind fetching 300 r. (22 $\frac{1}{2}$ 10s.) per "sen" (293 $\frac{1}{2}$ lb.), and the inferior quality 100 r. (7 $\frac{1}{2}$ 10s.) per "sen." Four parties of traders came from Luang Phrabang to Chiengmai with benzoin during 1890. A 3 per cent. duty was charged on this article in Bangkok.

Sticklac.

Sticklac is abundant in Chiengmai, and is sent down to Bangkok. Last year 8,800 lb. were bought there by one trader at prices varying from 80 r. (6 $\frac{1}{2}$ l.) to 90 r. (6 $\frac{1}{2}$ 15s.) per "sen" (293 $\frac{1}{2}$ lb.). The trade in sticklac was formerly much hampered by the heavy duty on it, which was 33 $\frac{1}{2}$ per cent. The duty was levied last year, but has now been taken off, and the trade, which has been in a moribund state for some time, may now perhaps revive.

GENERAL TRADE NOTES.

THE IRON INDUSTRY OF HUNGARY.

A. von Asbóth. *Chem. Zeit.* 1891, 15, 845.

The iron industry of Hungary has only been developed to any great extent during the last 2—3 years, i.e. since the native blast-furnace owners have entered into an agreement with their Austrian confrères. At present the Hungarian iron market is so active that the demand for various iron products exceeds the supply. Rolled iron, especially, has been in great request, and the price rose by 50 kreutzers in 1889 and again by 50 kreutzers in 1890 per 100 kilos. Considerable business was also done in girders, rails, boiler plates and sheet iron, iron beams, &c. used in building construction, and light sheet iron. The favourable influence of the "Cartell" on the Hungarian iron trade may be traced in the rise in value of the shares of various iron companies. The shares of the *Rimamórny-Salgótarjánér Iron Company* were quoted in 1886 at 83 florins; in 1890 they had risen to 158 florins; and similarly in the case of other companies. It is satisfactory to know that the agreement ("Cartell") with the Austrian manufacturers, which expired in 1890, has been renewed for three years.

The total production of the Hungarian refining and rolling works in 1890 was 200,000,000 kilos., compared with 166,000,000 kilos. in 1885. The pig iron for the purpose was all of native manufacture, and in consequence every existing blast-furnace was kept in full swing. In fact, in 1889 and 1890 the supply of native pig iron was not equal to the demand. The price of bloom iron rose from 2·80 florins in 1886 to 5 florins in 1890 per 100 kilos.

The production of raw iron in 1890 was 280,000,000 kilos. Most blast-furnace works also produce cast-iron goods, partly directly from the furnace iron and partly from more or less refined iron. The production of cast-iron ware in 1890 was 35,000,000 kilos. In 1885 240,000,000 kilos. of raw iron were manufactured.

During the year 1890 50 blast furnaces, 11 Bessemer converters, 9 Siemens-Martin furnaces, 28 gas regenerative double puddling furnaces, 7 puddling furnaces, and 26 forges, &c. were at work.—H. T. P.

THE METAL INDUSTRY OF HUNGARY.

A. von Asbóth. *Chem. Zeit.* 1891, 15, 881.

With the exception of Russia, there is scarcely any country so rich in metals as Hungary, which is nevertheless behind most European countries in the actual production of metals, a fact which must be ascribed to want of enterprise and capital. A large portion of the industry is carried on under Government auspices which favour antiquated methods of work and causes the industry to languish under the competition of newer and more economical processes. For the treatment of lead and copper ore, methods in the dry way are mostly in vogue, but a treatment in the wet way is sometimes used in working up the residues, and in the case of copper electrolysis is in some cases employed for precipitation of the metal from solution. In 1890 the production amounted to 10,670 centners of commercial lead, worth 188,503 fl.; 7,179 centners of lead glance worth 94,837 fl.; and 2,669 centners of copper, worth 169,073 fl. Of nearly 400 undertakings, for which concessions have been granted, a large proportion base their prospects on the possibility of finding gold. The largest gold-producing concern in Hungary is the Harkort Company in Brad. This firm turned out 687·630 kilos. of raw gold in 1890 against 467·035 kilos. in the previous year. The

total production of noble metals in Hungary is 2,304 kilos. of fine gold and 16,660 kilos. of fine silver, together worth 4,713,489 fl.—G. H. B.

PRODUCTION OF INFUSORIAL EARTH IN THE UNITED STATES.

Infusorial earth has been found in useful quantity in a number of places in California, Connecticut, Maryland, Nevada, New Hampshire, New Jersey, New Mexico, Oregon, and Virginia, but the production in 1889 was limited to five States, namely, New Jersey, New Hampshire, Connecticut, Maryland, and California. The bulk of the product was obtained from the Dunkirk district, in Maryland, the ledge at Dunkirk producing 3,000 short tons and all other localities 466 short tons. An excellent deposit of infusorial earth was opened at Pope's Creek, Md., in 1887, and a considerable quantity taken out, but owing to a slack demand only 50 tons were produced at this point in 1889. In Storey County, Nev., there is a mine of a fine quality of infusorial earth, but no work was done upon it in the census year. The following table shows the production of infusorial earth in 1889, by States:—

States.	Short Tons.	Value.
		Dols.
California*.....	50	8,000
Connecticut†.....	211	422
Maryland†.....	3,050	10,700
New Hampshire*.....	80	2,750
New Jersey*.....	75	1,500
Total.....	3,466	23,372

* Separated and ground.

† Crude at the mines.

The mines at Dunkirk, Maryland, were the only ones which were operated actively during the year. The total number of men employed in the industry was 52. The expenses incurred in mining infusorial earth during 1889 were as follows: Wages, 8,388 dols.; paid contractors, 575 dols.; paid for supplies, 760 dols.; paid for other expenditures (rent, insurance, taxes, &c.), 6,955 dols.; total, 16,678 dols. The amount of capital invested was: In land, 61,380 dols.; in buildings, machinery, &c. 21,900 dols.; in tools, implements, live stock, &c., 16,970 dols.; in cash, 10,500 dols.; total, 110,750 dols.

The table following shows the analyses of infusorial earths from different localities:—

	From Pope's Creek, Md.	From Morris County, N. J.	From near Richmond, Va.	From Storey County, Nev.
	Per Cent.	Per Cent.	Per Cent.	Per Cent.

Water at red heat.....	18'44
Loss.....	0'48
Total.....	100'00	99'09	98'95	100'00

Infusorial earth is used to a considerable extent in the manufacture of various cleansing preparations, either in the form of powder or so-called soap. There is but a step between the crude mineral and the merchantable articles used for cleansing purposes. To manufacture a polishing powder it is necessary only to clean and grind the crude mineral, the particles of which are loosely adherent, while in making soap the pulverised mineral is mixed with the other ingredients of soap manufacture. The greater portion of the product of this country is dried in furnaces at the pits and used for making protective coating for boilers. Some infusorial earth has been imported from Germany and used as an absorbent in the manufacture of dynamite from nitro-glycerin. The American product, however, does not possess sufficient absorbent properties for this purpose, and the German product has been supplanted by the use of wood pulp, which answers the purpose excellently and is much cheaper. The first development of infusorial earth properties in California was made in 1889. This was due to the discovery of a valuable ledge by Mrs. Emma Fells on her ranch near Calistoga, Napa County. By practical tests she learned that the mineral was excellently adapted for use as a polishing powder, and, with a number of ladies, organised a stock company for the purpose of mining and manufacturing the mineral.—*Census Bulletin*, No. 75.

THE AMERICAN CHEMICAL SOCIETY.

A conference of American chemists was held on August 18th, which was attended by delegates from the American Chemical Society (of New York City), the Washington Chemical Society, the Association of Official Chemists, the Cincinnati Chemical Society, the Brooklyn Institute, the Franklin Institute, the Association of Manufacturing Chemists, and the Louisiana Association of Sugar Chemists. For several years the chemists have been trying to get together to form a national society, but the American Chemical Society, the New York organisation, which was the leading one, did not wish to give up its name and be absorbed. It has, however, finally agreed that the national society shall be known by its name, and that it will become the New York branch. Each of the other local societies will retain its identity as a branch. This basis of agreement will be reported by the conferees to their respective societies for adoption, and the national organisation will be perfected at a general meeting, which will probably be held in October. The formation of the new American chemical society is a matter for congratulation to the chemists of the whole country.—*Eng. and Mining Journal*.

PRODUCTION OF FLUORSPAR IN THE UNITED STATES.

The production of fluorspar in the United States in 1889 was limited to one locality near Rosiclare, Ill. The product was 9,500 tons, valued at 45,835 dols., an increase of 3,500 tons over the product of 1888. The price remains about the same. The following table gives the quantity and value of fluorspar produced in the United States for all the years for which figures are obtainable:—

Years.	Short Tons.	Value.	Years.	Short Tons.	Value.
		Dols.			Dols.
1882	4,000	20,000	1886	5,000	22,000
1883	4,000	20,000	1887	5,000	20,000
1884	4,000	20,000	1888	6,000	30,000
1885	5,000	22,500	1889	9,500	45,835

The mining of fluorspar gives employment to about 100 men, who work on an average of 200 days in the year. The demand for the mineral is not heavy, and the mines are operated only about two-thirds of the time. The expenses incurred in the mining of fluorspar in the United States for the year 1889 were as follows:—Wages, 14,213 dols.; paid for supplies, 5,025 dols.; other expenses,

3,008 dols.; total, 22,246 dols. The amount of capital represented in the industry was 192,000 dols., distributed as follows: In land, 13,100 dols.; in buildings, machinery, &c., 12,500 dols.; in tools, implements, live stock, &c., 13,000 dols.; cash used as working capital, 35,500 dols.; total 192,000 dols.

Fluor-spar is used principally as a flux in melting iron in foundries, for the manufacture of opalescent glass, and for producing hydrofluoric acid for chemical purposes.

Fluor-spar (calcium fluoride) is not imported into the United States, but is obtained as a by-product in the reduction of cryolite to the salts of aluminium and sodium. All of the cryolite consumed in the United States is imported from Greenland. The amount of cryolite imported into the United States from 1871 to 1889, inclusive, is shown in the following table:—

Years.	Long Tons.	Value,	Years.	Long Tons.	Value,
		Dols.			Dols.
1871	..	71,058	1881	..	103,529
1872	..	75,195	1882	3,778	51,889
1873	..	84,226	1883	6,598	97,400
1874	..	20,118	1884	7,390	106,019

—Census Bulletin, No. 75.

PRODUCTION OF BARYTES IN THE UNITED STATES.

Barytes, or natural barium sulphate, is a well-known mineral and liberally distributed, but it is only recently that it has become of any commercial importance. Barium sulphate has been prepared artificially for a number of years, and is used to a considerable extent in the place of white lead, which it resembles closely. Improvements in machinery and in the process of treating natural barytes have overcome many of the objections which formerly existed to its utilisation, and considerable attention is now being given to the localities in the United States where it is found. The mineral, in order to be available for the uses to which it is put, must be fairly free from quartz grains, the stain of iron rust or other impurities. If the barytes is stained to any extent it is practically valueless, as a good white colour is essential to its usefulness. Quartz grains or other hard substances with which it is apt to be associated injure the machinery in grinding. The purest barytes so far produced in this country comes from Missouri, though a very fair grade is now being mined in considerable quantities in Virginia.

The returns from all producers of crude barytes show a product in the United States, for 1889, of 21,160 short tons, valued at 106,313 dols., against 20,000 short tons in 1888, valued approximately at 110,000 dols. The production was limited to four States, as shown in the following table:—

States.	Short Tons.	Value,
		Dols.
Illinois.....	200	1,300
Missouri.....	7,558	32,715
North Carolina.....	3,000	15,000
Virginia.....	10,702	57,298
Total.....	21,460	106,313

Barytes mining in Missouri is carried on in so irregular a manner that it is impossible to obtain any reliable statistics relative to labour and wages. Farmers mine it in off seasons; that is, when there is no farming to do, they employ themselves and their hands in getting out the barytes found on their farms, haul it to the nearest tradesman, and receive in exchange dry goods, groceries, or other necessities, or cash. The farmers thus occupy time which would otherwise be idle, and dispose of the barytes at a less figure than it would pay to mine it systematically. The supply thus obtained is nearly sufficient to keep the mills up to their fullest capacity.

A few mines are, however, operated with some degree of system, though for want of proper records it is necessary to estimate a considerable portion of the matter of labour and wages. The mines altogether give irregular employment to about 580 men. The rate of compensation for foremen is about 2.50 dols. per day, and for labourers from 1 dol. to 1.50 dols. per day. It is rarely, however, that the men make full time, and their daily earnings are reported at from 50 to 75 cents. From 75 to 100 women obtain the same sort of irregular employment, earning about 35 cents per day. Boys get from 25 to 30 cents per day. One mine was active nearly the entire year, but in most cases the number of days worked at the mines ranged from 125 to 200.

The following statement shows the amount of money paid for operating and developing barytes mines in Virginia, North Carolina, and Illinois: Wages (including office force at mines), 54,524 dols.; paid for supplies, 8,200 dols.; other expenditures (rent, taxes, insurance, &c.), 2,083 dols.; total, 64,807 dols. The amount of capital represented in barytes mines in the United States, worked in 1889, was as follows: In land, 181,450 dols.; in buildings, machinery, &c., 66,450 dols.; in tools, implements, live stock, &c., 76,350 dols.; cash, 23,900 dols.; total, 351,150 dols. The aggregate value of the lands on which barytes is found in Missouri is placed at 4,500,000 dols., but the estimates are based on prospects rather than on actual development.

The consumption of barytes seems to be steadily increasing. It is used quite extensively in the arts, finding its greatest service as an adulterant in the manufacture of paint. Its great weight, its likeness in many respects to white lead, and the fact that it can be used in place of that commodity, enable manufacturers to replace the costlier article with a substitute much to their own advantage. It is claimed by some that a mixture composed of one-third barytes, one-third zinc white, and one-third white lead makes a better paint than the pure white lead. This is probably true for some special purposes. Barytes is remarkable for its weight, having a specific gravity of about 4.5, or about the same as iron ore. It can therefore be used with white lead without any appreciable loss of weight in the mixture.

Besides the localities from which the supply has been thus far derived, there are deposits in South Carolina which are now being investigated with prospects of development at an early date. The mineral is found along the line of the Charleston, Cincinnati, and Chicago railroad, in the building of which a considerable vein was exposed, but occurs in largest quantities in the vicinity of King's Creek, where a side track can be run in and the material loaded on cars. Lack of transportation was one of the drawbacks to its development in the past, but this difficulty has been removed by the railroad builders. Diffused through the barytes is a small percentage of quartz grains, which make it necessary to use other grinding machinery than the buhr mills ordinarily used for that purpose. It is expected that mills for this purpose will be put up in the vicinity of the mines, thereby insuring a more profitable business than can be obtained by sending the barytes elsewhere to be ground and floated.

At Terrazas station, State of Chihuahua, Mexico, there are some six or eight veins of barytes from 1 to 5 ft. thick, said to be of a good white colour, free from yellow, brown, or black iron stains, and a considerable portion of which has a very delicate pale blue tint, considered valuable in the highest classes of barytes, as it tends to neutralise the yellowish tint of inferior qualities. The company

owning the property upon which these veins are found offered to sell the barytes in ear loads at 5 dols. per short ton, free on board cars at the shipping point.

Nearly all, if not all, of the barium sulphate imported into the United States is artificially prepared. Importations are quoted under various names, such as blane-fixe or permanent white, satin white, enamelled white, lime white, &c. The imports of manufactured barium sulphate in 1889 amounted to 3,601,506 lb., valued at 22,458 dols.; manufactured, 13,571,206 lb., valued at 7,660 dols.—*Ibid.*

GERMAN DRUG IMPORTS.

The following figures, representing the imports of some of the principal drugs and dysaltries into Germany, are taken from recent official statistics published in that country:—

Years.	Cinchona Bark.	Cochineal.	Gum Arabic and Tragacanth.	Shell, Seed, and Stick Lac.	Campbor.
Tons (average).					
1872-75	1,028	523	1,363
1876-80	967	308	1,084
1881-85	2,876	111	1,513	1,135	(1885) 183
1886	4,673	97	1,201	1,124	157
1887	4,222	67	1,081	1,613	332
1888	4,671	77	1,110	1,396	378
1889	5,120	35	1,318	919	353

—*Chemist and Druggist.*

THE NITRATE COMBINATION.

The recent formation of a combination of nitrate of soda producers has been followed by a considerable advance in the quotations for the article. The combination, it is said, have decided to reduce the total export during the present year to 18,000,000 quintals, equal to 800,000 tons. Last year the total exports were 1,043,000 tons.—*Ibid.*

WEST AFRICAN GUM ARABIC.

Mr. Levan Millson, who has lately been commissioned to investigate the resources of Yoruba land (B. W. Africa) reports that in the territories visited by him the supplies of gum-yielding trees of the kind called "Akkow L'odo" by the natives (*Brachystegia*, n. sp. ?) is practically unlimited. The trees yield a gum apparently of the acacia description, and similar to gum arabic. The gum could only be gathered during the dry season.—*Ibid.*

CHEMICAL PATENTS IN GERMANY.

In seeking to protect an invention by a patent, it is sometimes difficult to decide what constitutes the patentable principle of the invention, and in what manner the claims must be limited. According to the Chemiker Zeitung, this important question has now been cleared up, as far as Germany is concerned, by a decision of the highest court of that country (the Reichsgericht at Leipzig) as follows:—

If a valuable product is obtained by a previously unknown application of a known process the new application of the process is patentable. A process can only be patented as far as its effect has been recognised and described by the inventor at the time of applying for a patent. The fact that a patent could be circumvented will not justify the inventor to frame the claims in such a manner that they exceed the limits of the actual invention. A patent cannot be founded upon a rule, if that rule has any exception, and if the absence of any exception has not been recognised and mentioned. If, nevertheless, such a patent has been granted, and if the party applying for the revocation of

the patent has proved that the rule embodied in the claim is not applicable everywhere, he cannot be required to prove in which individual cases the invention does not give the required result. The general idea to obtain by a process a useful result is not patentable, but only a definite and practically realisable method of carrying that idea into effect. The use of a known substance for the production of another known substance can only be patented as an invention if the process employed is new and patentable.—*J. Wetter.*

RULES OF LEGAL PROCEDURE AGAINST FOREIGN FIRMS.

Some new Rules of Court have just received the sanction of the Lord Chancellor, which will prove of great importance to commercial firms. They lay down the rules to be observed in regard to bringing actions against foreign firms, which have hitherto, owing to conflicting opinion, been of much difficulty and very perplexing. There have always been two very pronounced difficulties, viz., whether the firm should be sued in the name of the firm or in the names of the partners, and whether the writ should be served upon the partners in this country, or on one partner only, or all the partners. As a consequence it frequently happens that foreign firms, either carrying on business by a branch in this country, or having their businesses wholly abroad, but making a contract here, either wholly escaped or forced their British creditors to go to a foreign country for redress. This has been entirely removed, for it has been decided that those partners who happen to be in this country can be sued, and that if there is a branch of the firm here a summons or writ must be served in the name of the firm, and at their office, to anyone who appears to be in authority there.—*Chemist and Druggist.*

Monthly Patent List.

* The dates given are the dates of the Official Journals in which acceptances of the Complete Specifications are advertised. Complete Specifications thus advertised as accepted are open to inspection at the Patent Office immediately, and to opposition within two months of the said dates.

 I.—GENERAL PLANT, APPARATUS, AND
MACHINERY.

APPLICATIONS.

13,875. E. Casper and W. Sowerby. Improvements in drying moulds. August 17.

14,221. J. Tobin. A new method of applying soda to internal parts of boilers for preventing the formation of scale. August 22.

14,440. W. Arrol and W. Foulis. See Class II.

14,610. O. Intze. Improvements relating to gas-holders. August 29.

14,861. W. W. Horn.—From J. Stanard, United States. Improvements in refrigerators. September 2.

14,870. W. E. Proctor. Improvements in evaporators, to be known as "Proctor's system of evaporising." September 3.

14,986. P. Borgarelli. Improvements in apparatus for drying grain and other granular or pulverulent materials. September 4.

15,092. O. Lindemann. Improvements in steam and vacuum pumps for raising liquids. Complete Specification. September 7.

15,192. O. M. Row. Improvements in apparatus for condensing steam or other vapours, also applicable for heating or cooling fluids. September 8.

15,367. J. Kent and F. S. Toney. An improvement in thermometers. September 10.

15,441. J. Molas. Improvements in apparatus for detecting and indicating the presence of explosive gases in mines and other places. September 11.

COMPLETE SPECIFICATIONS ACCEPTED.*

1890.

14,051. H. Rouart. Sterilising water and other liquids, and apparatus therefor. September 2.

15,976. G. J. Davis and E. Jones. Manufacture of compounds suitable for coverings for floors, walls, ceilings; also for tubes, insulating coverings, and other purposes. September 16.

16,384. J. Dunn. Apparatus for drying semi-liquid granular or pulverulent substances. August 26.

16,404. T. E. Caddy. Improvements in or relating to furnaces. September 16.

16,528. T. E. Wilson. Apparatus for evaporating, distilling, or concentrating liquids. August 26.

16,679. W. H. Le Mesurier. Apparatus for refrigerating air; also applicable to the evaporation of liquids. August 26.

17,117. D. Rylands. Means of manufacturing glass vessels and adapting the same for the storage and conveyance of compressed gases, and for similar purposes. September 16.

17,237. P. Callibures. System of apparatus for evaporation and distillation. September 9.

17,702. C. J. Copeland. Apparatus for feeding fuel to gas producers. September 2.

17,815. F. Ellershansen. Reverberatory furnaces. September 9.

1891.

6485. P. M. Pinal, V. Lethuillier, and C. L. Pinal. Liquid gauges. August 26.

9311. W. P. Thompson.—From J. A. Bowden. Filters. August 26.

12,111. W. McLaren and P. Holmes. Refrigerating medium. August 26.

12,389. H. C. Sergeant. Compound compressors for air and other gaseous or aeriform bodies. August 26.

12,796. B. Rottenmeyer. Cooling apparatus for liquids. September 2.

12,805. R. P. Earnstead, R. H. Spalding, and J. C. Ballard. Water distilling apparatus. September 9.

1891.

3031. F. Fanta. New process for producing oxygen gas. September 2.

4131. V. B. Lewes. Manufacture or production of hydrogen. August 26.

5022. J. Moeller. Incandescent illumination, and apparatus for that purpose. September 2.

7983. A. A. Dixon. Apparatus for the manufacture of crude peat into fuel. September 2.

8067. T. Keetman and W. Bach. Charging and discharging gas retorts and other vessels. August 26.

8893. A. Parks. See Class XVII.

II.—FUEL, GAS, AND LIGHT.

APPLICATIONS.

11,030. B. Redwood, R. Redwood, and H. Barringer. A method of and apparatus for measuring depth of water in oil tanks. August 19.

11,110. W. Arrol and W. Foulis. Improvements in apparatus for charging gas and other retorts, and in part applicable for other purposes. August 26.

11,518. C. C. Black and S. Alford. The utilisation of shale and other colliery waste. August 28.

11,978. G. Eastham. Improvements in firewood relating to increase of combustible energy. September 4.

15,105. W. C. Owston. An improved fire-lighter. September 7.

15,219. W. R. Lake.—From A. Henkin, United States. Improvements relating to the manufacture of ammonia and gas. Complete Specification. September 8.

15,286. The Incandescent Gas Light Co., Lim.—From C. A. von Weltsch, Austria. An improved manufacture of incandescence bodies. September 9.

15,305. The Manchester Oxygen (Brin's Patent) Co., Limited, and W. M. Jackson. Improvements in the manufacture of oxygen. September 10.

15,390. H. Williams. Improvements in apparatus for use in the manufacture of illuminating gas. September 11.

15,413. L. H. Arneuir. Improvements in or connected with the manufacture of illuminating or heating gas. September 11.

15,469. H. Furness. Improvements in the manufacture and storage of illuminating and heating gas. September 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

11,721. J. Busch. Apparatus for charging and drawing gas retorts. September 9.

11,906. C. W. Jones. The revivification of materials employed for the purification of coal gas, and treatment of the residues. September 9.

11,925. J. H. Parkinson. Obtaining or separating oxygen from atmospheric air. September 9.

15,388. J. F. Bradwood. Method of and apparatus for charging retorts for the manufacture of gas and other like purposes. August 26.

16,213. A. Coze. Apparatus for charging inclined gas retorts. August 26.

16,816. F. E. Ross. Method of and apparatus for producing gases from bituminous fuel. August 26.

20,752. V. B. Lewes. Manufacture of hydrogen gas, or a mixture of hydrogen and carbon monoxide, and apparatus therefor. August 26.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

APPLICATIONS.

11,548. C. C. Black and S. Alford. See Class II.

11,651. J. Weirich. See Class XII.

15,287. L. Hugues. Improvements in apparatus for distillation of fatty acids and other substances. September 9.

IV.—COLOURING MATTERS AND DYES.

APPLICATIONS.

13,831. J. Dawson and Co., Limited, and J. H. Lutkehermölle. A process of obtaining new basic compounds and colouring matters therefrom. August 17.

14,291. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. The manufacture and production of new sulpho-acids, and of new colouring matters therefrom. August 24.

11,666. J. Frost and E. C. Kayser. Improvements in preparing colouring matters, and in dyeing textile fibres and similar materials. August 31.

14,723. J. Y. Johnson.—From The Badische Anilin und Soda Fabrik, Germany. The manufacture and production of new dyes related to the rhodamine series. August 31.

15,113. J. A. Hewitt.—From L. Cassella and Co., Germany. Manufacture of blue dyestuffs. September 7.

15,194. The Clayton Aniline Co., Limited, and J. Hall. Improvements in the manufacture and production of colouring matters. September 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

17,195. D. Dawson. Production of blue colouring matters. September 9.

18,024. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brünig. Production of a novel piazolone. September 16.

18,025. O. Imray.—From The Farbwerke vormals Meister, Lucius, and Brünig. Production of sodium formylphenylhydrazine and of symmetric alkylphenylhydrazine. September 16.

18,729. B. Willecox.—From The Farbenfabriken vormals F. Bayer and Co. Manufacture of new derivatives of anthraquinone. September 16.

1891.

1742. S. Pitt.—From L. Cassella and Co. Manufacture of a new amidonaphtholsulphonic acid, and colouring matters therefrom. September 16.

11,218. H. H. Lake.—From K. Oehler. Manufacture of colouring matter. August 26.

V.—TEXTILES, COTTON, WOOL, SILK, Etc.

APPLICATIONS.

13,967. E. Appenzeller and E. Filleul. An apparatus for testing the strength of cotton, wool, and other fibres in the raw or unmanufactured state. August 19.

14,272. J. C. Chapman.—From the United Indurated Fibre Co., United States. See Class XIX.

COMPLETE SPECIFICATION ACCEPTED.

1891.

12,817. A. J. Boulton.—From B. Beyer. Manufacture of yarns and fabrics from waste silk, and washing the resulting material. September 9.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

APPLICATIONS.

9228A. E. A. Marchand. See Class VII.

13,955. W. J. S. Grawitz. Improvements in dyeing and printing textile fibres with aniline and its homologues or derivatives. Complete Specification. Filed August 18. Date applied for January 19, 1891, being date of application in Belgium.

14,657. E. Gessler. Improved process and apparatus for the treatment of textile fibres with liquids and vapours or gases. August 29.

14,666. J. Frost and E. C. Kayser. See Class IV.

15,174. A. Graemiger and J. Graemiger. Improvements in apparatus for dyeing, scouring, bleaching, and otherwise treating yarn in cop or other similar compact form. September 8.

15,263. S. Knowles. Improvements in keirs employed in dyeing and otherwise treating yarn and other materials. September 9.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

14,302. T. Ingham. Dyeing cotton. September 9.

14,839. O. Hoffmann. Process and appliances for washing, bleaching, and dyeing fibrous materials. September 2.

16,751. W. Laidlaw. Method of and apparatus for dyeing yarns, tops, and the like. August 26.

17,326. C. D. Abel.—From M. M. Rotten. Dyeing textile materials of all kinds in the hyposulphite vat. August 26.

19,158. P. J. Grandsire. Machinery for dyeing skeins or banks. September 2.

VII.—ACIDS, ALKALIS, AND SALTS.

APPLICATIONS.

9228A. E. A. Marchand. A process for preparing alkaline permanganates for bleaching purposes. August 25. Originally included in No. 9228, and therefore dated June 1, 1891.

13,869. W. Walker. See Class VIII.

14,159. T. Parker and A. E. Robinson. Improvements in the treatment of solutions containing nickel and iron for the obtainment of useful products therefrom. August 21.

14,213. H. Y. Castner and H. Baker. Improvements in the manufacture of salicylic acid. August 22.

14,342. H. W. Wallis. Improvements in the regeneration of the alkaline sulph-ferrites of soda waste, with recovery of elemental sulphur, and reproduction of sodium ferrite, carbonate, and hydrate. August 25.

14,868. R. C. Wilson. Improvements in or connected with the manufacture of salt from brine. September 3.

14,944. K. Walter and E. Boenig. Improvements in lead chambers used in the manufacture of sulphuric acid. Complete Specification. September 4.

15,116. G. J. Warner. Improvements in the utilisation of metallic chloride and other waste liquors, and in the production of valuable products therefrom. September 7.

15,136. F. Fiechtstädt. A process for the production of caustic alkali, carbonate of alkaline metals, and useful by-products. Complete Specification. September 7.

15,251. C. G. Collins. Process for purifying brine. Complete Specification. September 8.

15,288. R. J. Briece. A process of utilising galvaniser's waste. Complete Specification. September 9.

15,357. The Compagnie Générale de Produits Antiseptiques, H. Gall, G. de Beehi, and the Société Centrale de Produits Chimiques. See Class XVIII.—C.

15,515. A. Vogt. Improvements in the treatment of nitrate of an alkali for the manufacture of nitric acid and fertilising compounds. September 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

14,084. E. Meyer. Manufacturing hydrate of alumina from silicates of alumina or clay. September 9.

17,765. J. Simpson. Employment of sulphuretted hydrogen in the manufacture of alkali and certain by-products. September 9.

1891.

8293. H. H. Leigh.—From J. Elsner and R. Gaseh. Process and apparatus for procuring cyanogen and its compounds from gases. September 9.

11,965. P. de Wilde. Method of utilising the "Weldon" plant for the manufacture of precipitated phosphates. August 26.

13,334. A. L. H. Knoop. Extraction of carbonic acid from minerals, and apparatus therefor. September 16.

VIII.—GLASS, POTTERY, AND EARTHENWARE.

APPLICATIONS.

13,869. W. Walker. Improved process and apparatus for making glass and obtaining hydrochloric acid. August 17.

14,064. L. Wilson. Improvements in and connected with blocks and tiles for paving and flooring, for facing walls and ceilings, and for similar purposes. August 20.

14,076. J. Sherwin. Improvements in the encaustic method or process of decorating tiles, plaques, and other articles of earthenware, china, and stoneware. Complete Specification. August 20.

14,164. J. P. Guy. Improvements in the manufacture of solid earthenware articles, such as tiles and bricks, and in machinery or apparatus therefor. August 21.

14,381. C. G. y Losada. Improvements in baking ceramic pastes and pottery. August 25.

14,482. D. Rylands. Improvements in connexion with glass-melting furnaces. August 27.

14,496. C. L. Startup. Improvements in machines for blowing glass. August 27.

14,918. J. P. Guy. Improvements in the manufacture of earthenware articles, such as tiles and bricks, and in machinery or apparatus therefor. September 3.

15,067. A. Cay. Improvements in the manufacture of certain kinds of articles of glass, and in machinery or apparatus to be employed in the said manufacture. September 5.

15,108. E. G. Cole and H. Keston. Improvements in means or apparatus for forming clay into pots or vessels. September 7.

15,210. H. Warrington. Improvements in or applicable to ovens or kilns for burning porcelain, bricks, tiles, and the like. September 8.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

15,301. D. Rylands. Machinery for manufacture of bottles and other hollow glass ware or pressed ware. September 16.

16,629. G. L. Schultz. *See Class X.*

17,117. D. Rylands. Manufacturing glass vessels, and adapting the same for the storage and conveyance of compressed gases, and for similar purposes. September 16.

IX.—BUILDING MATERIALS, CLAYS, MORTARS, AND CEMENTS.

APPLICATIONS.

13,836. W. H. Munns. From H. A. Rue, jun., United States. An improved mill for grinding hard substances. August 17.

13,983. W. P. Winter. Improvements in and relating to securing moulds in the manufacturing of artificial stone, paving, and other uses. August 19.

14,600. W. J. Lea, W. Murray, and A. Bates. The improved compound granulate fire-lighting and fire-resisting cement, and also of boiler and steam pipe and service pipe covering. August 29.

14,952. J. S. Robertson. Interlocking impervious brick. September 1.

15,101. E. Lodge and F. Jury. A new or improved chemical treatment or application for cleaning stone, marble, granite, and the like. September 7.

15,139. F. Haines. Improvements in constructing cement or the like pavements, floors, platforms, or other surfaces or structures. Complete Specification. September 7.

15,195. C. Tompkins and J. A. Kinder. Improvement in buildings, fireproof walls, partitions, and roofs. September 8.

15,281. W. F. Thomas. An invention for the decoration of artificial stone and pavements. September 9.

15,509. G. Dolenz. An improved process for the manufacture of artificial stone and marble. September 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

14,398. C. von Forell. Manufacturing from Roman cement a composition similar to Portland cement. September 16.

16,789. R. Stone. Manufacture of fireproof plastic material for cement, also applicable to smelting and various other useful purposes. September 9.

X.—METALLURGY, MINING, Etc.

APPLICATIONS.

13,888. J. E. Stead. Carbonising fluid iron and steel. August 18.

13,906. J. H. Darby. Improvements in or appertaining to basic-lined furnaces. August 18.

13,907. J. H. Darby. Improvements in the manufacture or treatment of steel or iron bars, plates, or the like. August 18.

14,031. O. Imray. — From F. C. Glaser, Germany. Process for hardening the interior of iron or steel tubes. August 19.

14,155. J. B. Freeman and others. An improved method of and apparatus for flaking or "feathering" lead or other metal. August 21.

14,251. A. French and W. Stewart. Improvements in obtaining nickel and cobalt from ores. August 24.

14,290. H. L. Herrenschildt. Improvements in the treatment of certain mattes and ores for the separation of nickel and cobalt from copper. August 24.

14,449. H. Pieper. A new or improved process for the production of damascened metal bars for use in the manufacture of fire-arm barrels. August 26.

14,737. W. D. Bohm. Improvements in apparatus for leaching ores in separating gold and silver therefrom. September 1.

14,791. E. Edwards. — From L. Pszcolka, Germany. An improved process for the manufacture of compound armour plates and armour-plated turrets. September 1.

14,795. E. Martin. An improved manufacture of compound or metal coated wires. September 1.

14,823. W. H. Martin and W. Pethybridge. The Martin-Pethybridge gold extraction apparatus. September 2.

14,825. W. R. Hinsdale. Process of preventing segregation in large ingots. September 2.

14,951. E. L. Mayer. A new or improved process of extracting antimony from certain of its ores and compounds. September 4.

15,148. The London Metallurgical Co., Lim., and S. O. Cowper-Coles. Improvements relating to the coating or plating of metals and metallic articles, which improvements are also applicable for the manufacture of bullets. September 5.

15,142. W. R. Lake.—From G. F. Simonds, United States. Improvements relating to the hardening or tempering of steel, and to apparatus therefor. September 7.

15,204. J. von. Langer and L. Cooper.—From G. Pietzka, Austria. Improvements in reverberatory or open-hearth furnaces. September 8.

15,288. R. J. Brice. See Class VII.

15,359. J. A. Crawford. Improvements in the manufacture of malleable and gun iron by the hand-puddling system. September 10.

15,418. J. E. C. Koch.—From W. E. Koch, United States. Improvements relating to the production of metallic oxides and to apparatus therefor. September 11.

15,444. T. H. J. Eskuchen and H. A. Haarmann. Improvements in the burning of pressed blocks of purple ore and in apparatus or kilns therefor. September 11.

15,482. T. H. J. Eskuchen and H. A. Haarmann. Improvements in the manufacture of briquettes of purple ore. September 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

12,831. E. Zappert.—From C. Searneo. Manufacture of material to be employed in the manufacture of armour plates. August 26.

13,413. T. Held. Obtaining a new metallic alloy. August 26.

15,102. T. Sturgeon and T. C. P. Crampton. Method of casting metals in moulds. September 16.

15,806. A. J. Campion and J. E. Tenison-Woods. Treatment and reduction of metallic ores or compounds, and recovery of metals and products therefrom. August 26.

16,629. G. L. Schultz. Extraction of iron from minerals used in manufacture of glass, china, earthenware, and similar goods. September 16.

16,694. J. Harris. Machinery or apparatus to be used for the extraction of gold and silver from their ores by the amalgamation process. August 26.

16,887. T. S. Lindsay. Preparation of aluminium fluoride and double fluorides, and manufacture of aluminium from fluoride. September 9.

17,053. W. Turan. Machinery or apparatus for cooling or discharging slag. September 16.

17,623. J. Garnier. Process for the manufacture of metallic nickel, together with alloys of nickel and iron, utilisable either direct or for the manufacture of nickel steel or nickel and carbonised iron castings. September 16.

17,625. B. Richards. Furnaces for smelting copper and other ores. September 9.

17,935. N. Lébédoff. Means or apparatus for the extraction of metals from metallic ores or matters containing metals. August 26.

18,276. J. Riley. Ingot moulds, used in the manufacture of steel. September 16.

21,221. W. D. Bohn. Apparatus for the separation of gold and silver from ores or materials containing them. September 16.

1891.

946. N. Lébédoff. Extracting iron or steel or other metals from ores or metalliferous materials. August 26.

9686. A. Longsdon.—From F. Asthower. Compound armour plates. September 9.

11,563. C. James. Method and process for the production of zinc or spelter from ores or compounds containing the same. September 9.

12,165. J. Wilmotte. Converter for the manufacture of iron and steel. August 26.

12,405. J. W. Richards. Manufacture of galvanised iron. September 2.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

APPLICATIONS.

14,518. H. Weymersch. An improved construction of primary battery. August 27.

14,702. H. Hauser. Improvements in or connected with accumulators or secondary batteries. August 31.

14,800. H. H. Lake.—From H. Lemp, United States. Improvements in and relating to electric metal-working apparatus. September 1.

14,967. G. Steinle. Improved process and apparatus for extracting aluminium and its alloys by electrolysis. September 4.

15,050. E. A. Le Sueur. Improvements in or connected with electrolysis. September 5.

15,123. H. Edmunds. Improvements in or connected with systems of electric distribution wherein electrical storage batteries are used. September 7.

15,125. A. J. Jarman. Improvements in electrical storage cells and elements therefor. September 7.

15,407. G. Cohen. Improvements in galvanic batteries. September 11.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

18,896. A. S. Elmore. Process and apparatus for manufacturing copper tubes, sheets, strips, and wires by electrolysis. August 26.

1891.

7949. P. Goward. Secondary batteries. September 16.

11,134. C. A. Faure. Apparatus for the electrolysis of aluminium. September 16.

12,069. H. D. Fitzpatrick.—From K. F. Scholler and R. H. Jahr. Electrodes for secondary batteries. August 26.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

APPLICATIONS.

14,327. E. Simpson, C. H. Simpson, and H. McPhail. Improvements in the manufacture of soap. August 25.

14,365. O. K. Thomassen. Improvements in apparatus for purifying waste oil. Complete Specification. August 25.

14,651. J. Weirich. Improvements in the distillation and rectification of stearic acid, raw fatty acids, and tars. August 29.

14,902. J. Cathrein. Improvements in the method of and means for manufacturing soap. September 3.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

16,025. W. H. Lever, J. D. Lever, and E. G. Scott. Plant or apparatus for extracting oil or grease from granular or pulverulent material. September 2.

16,059. C. A. O. Rosell and J. C. Pennie. Manufacture of soap. August 26.

16,579. W. Wright. Improved soap powder. September 16.

XIII.—PAINTS, PIGMENTS, VARNISHES, AND RESINS.

APPLICATIONS.

14,137. R. W. E. Melvor. The production of the pigment known as blue ultramarine from the material known as green ultramarine by a new process. August 21.

14,160. A. McCowatt. An improved anti-fouling composition for ships' bottoms. Complete Specification. August 21.

14,518. J. C. Martin. Improvements in the manufacture or treatment of sulphate of lead. August 29.

14,948. H. Seiling. Paint. September 4.

15,330. S. Banner. Improvements in substances applicable for varnish, and in the method of manufacturing the same. September 10.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

11,359. J. Baptista. Facilitating the use of mineral or other non-oxidising oils in compounding paints and paint oils. September 2.

1891.

10,524. A. L. Rath. Manufacture of india-rubber. September 9.

10,528. A. F. B. Gomess. Process of devulcanising vulcanised india-rubber, gutta-percha, and similar gums, and reclaiming the rubber therefrom for re-manufacture, without the addition of pure rubber. August 26.

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

APPLICATIONS.

14,174. T. Dunn. An improvement in the production or manufacture of leather. August 22.

14,291. H. Courtonne. Improvements in the treatment of skins used in the felt manufacture. August 24.

XV.—AGRICULTURE AND MANURES.

APPLICATIONS.

14,719. H. W. Wallis. Improvements in the manufacture of fertilising compounds. August 31.

15,258. M. C. Gunster. Improvements in the manufacture of manure and fertilisers. September 9.

15,515. A. Vogt. See Class VII.

XVI.—SUGARS, STARCHES, GUMS, Etc.

APPLICATION.

14,575. A. Schneller and W. J. Wisse. Improvements in the refining of sugar juice or molasses. August 28.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

13,144. J. Y. Johnson.—From A. L. Peck. Manufacture of lactose or milk sugar. August 26.

17,557. A. Whol and A. Kollrepp. Production of invert sugar. September 9.

1891.

8893. A. Parks. See Class XVII.

12,058. R. F. Cordero. Apparatus for defeating and evaporating saccharine juices. August 26.

12,808. R. F. Cordero. Apparatus for washing sugar. September 9.

XVII.—BREWING, WINES, SPIRITS, Etc.

APPLICATIONS.

13,953. A. J. Boul.—From H. Lissagaray, France. Improvements in the distillation of wine, and of various simple or compound alcoholates, and in apparatus therefor. August 18.

14,053. H. Wilson. An improvement relating to brewers' and distillers' refrigerators. August 20.

14,117. F. A. J. Fitzgerald and G. Prescott. A method of restoring fermented liquors which have turned or are turning "flat." August 21.

14,276. A. Bruns. A process and apparatus for the production of sparkling wines and other sparkling beverages. August 24.

14,658. F. J. Money. Improvements in malt-mashing apparatus. August 29.

14,779. J. E. Johnson-Johnson. Improvements in the manufacture of materials for the production of alcoholic and non-alcoholic beverages, and apparatus therefor. September 1.

15,467. S. A. Croxford. An improved method of and apparatus for straining brewers' wort. September 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

15,352. H. H. Lake.—From A. Brunn, Denmark. Manufacture of yeast. September 9.

1891.

8893. A. Parks. Utilising the waste of distilleries, breweries, glucose and starch works, for the preparation of fuel. August 26.

12,506. C. Bach. Preparation of wort from malt alone or mixed with unmalted cereals. September 16.

XVIII.—CHEMISTRY OF FOODS, SANITARY CHEMISTRY, AND DISINFECTANTS.

APPLICATIONS.

A.—Chemistry of Foods.

13,873. W. R. Dodd. Improvements in the preparation of food for infants. August 17.

13,921. C. Reil. Improvements in the manufacture of bread. August 18.

14,521. J. Falcimagne. Improvements relating to the preservation of meat and to apparatus therefor. Complete Specification. August 27.

14,755. E. Wilhelm, A. Brougier, and H. Trillich. A method and apparatus for manufacturing malt coffee. September 1.

15,389. A. Davey. Improvements in or connected with the preparation of the banana as an article of food. September 11.

B.—Sanitary Chemistry.

14,038. J. Makinson. Improvements in apparatus for treating foul air and noxious vapours or gases. August 19.

14,181. W. D. Scott - Moncrieff. Improvements in or relating to the treatment of sewerage and other contaminated liquids. August 22.

14,394. J. Russell. Improvements relating to the treatment of sewer gas. August 25.

14,735. E. Devonshire. Improvements in apparatus for purifying or treating water. Complete Specification. September 1.

15,172. R. S. Brownlow. Improvements in apparatus for purifying water or other liquids. September 8.

15,391. F. P. Candy. Improvements in the oxidation of sewage and impure waters and of material for use in the treatment of such sewage and impure waters. September 11.

C.—Disinfectants.

14,788. H. H. Lake.—From A. G. Pummerer, Austria. An improved fluid insecticide. September 1.

15,357. Compagnie Générale de Produits Antiseptiques, H. Gall, G. de Bechi, and Société Centrale de Produits Chimiques. Improved manufacture of sulphate of copper. September 10.

COMPLETE SPECIFICATIONS ACCEPTED.

A.—Chemistry of Foods.

1890.

14,051. H. Ronart. See Class I.

15,981. W. Geddes. Improved malted feed preparations. September 2.

16,508. G. W. Homer and J. Hazel. Manufacture of cream, and the protection of cream, meat, fish, and other perishable articles from atmospheric air and other influences. August 26.

16,857. M. A. E. Schueider and R. H. Coall. Treatment of a certain fruit in order to convert it, either alone or combined with other substances, into food and drink for infants, invalids, and others. September 2.

B.—Sanitary Chemistry

1890.

17,453. J. W. Slater and the Native Guano Co., Lim. Preparation of agents for use in the purification of sewage and other polluted water by precipitation, and treatment of sewage and other polluted water, in order to effect the purification thereof. September 2.

1891.

4243. C. W. Chancellor. Method and apparatus for the treatment and disposal of sewage. September 2.

C.—Disinfectants.

1891.

3242. F. Idle and F. Pearson. Fire-lighter and disinfectant. September 9.

XIX.—PAPER, PASTEBOARD, Etc.

APPLICATIONS.

14,032. J. D. Tompkins. An improvement in the treatment of vegetable fibre for pulp manufacture. Complete Specification. August 19.

14,272. J. C. Chapman.—From the United Indurated Fibre Co., United States. Composition of matter for water-proofing pulp articles. Complete Specification. August 24.

14,652. E. W. H. Walker. An improvement in the treatment of paper before printing on same. August 29.

14,756. C. Schaeffelen. Process and appliance for producing fine granulated paper with uniform grain of pyramidal shape. Complete Specification. September 1.

14,897. A. Schlumberger. Process for producing safety paper by means of water-mark. September 3.

14,973. A. Schlumberger. Process for producing paper safe against forgery. September 4.

15,222. C. W. Robinson. Improved machine for making parchmentised fibre, &c. September 8.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

15,408. E. Misch. Manufacture of cellulose. September 9.

16,546. B. J. Beckmann. Manufacture of paper, pasteboard, and the like, and apparatus therefor. August 26.

16,928. H. B. Watson and J. S. Watson. Manufacture of strainer or knoter plates for straining paper pulp, wood pulp, and the like. August 26.

1891.

12,970. C. Kellner. Boiling process for producing cellulose by means of sulphurous acid. September 9.

12,971. C. Kellner. Process and apparatus for preparing the wood in the manufacture of wood fibre. September 9.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES, AND EXTRACTS.

APPLICATIONS.

14,223. G. A. Clowes. Improvements in the preparation of peptone extracts, and in the application of the same to various useful purposes. August 22.

14,224. P. Ernert.—From P. Ernert, Germany. A process for the preparation of phenylester salicylic acid or salol from salicylic acid. August 22.

14,430. A. Schmitz and E. Toenges. Process for the production of oxysebaeic glycerin ethers and oxy-sebaeides, as well as the derivatives: sulpho-oxy, di-oxy, and sulpho-dioxy-sebaeides. August 26.

15,514. S. Pitt.—From R. Pietet and Co., Germany. Improvements in the purification of chloroform. Complete Specification. September 12.

COMPLETE SPECIFICATIONS ACCEPTED.

1890.

18,021. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co. Manufacture of periodides of isobutyl phenols, and of isobutyl cresols. September 9.

18,022. B. Willeox.—From The Farbenfabriken vormals F. Bayer and Co. Manufacture of methyl- and ethylphenacetin. August 26.

18,246. O. Imray.—From The Amsterdamsche Chinine-fabrik. Production of anthranilic acid. August 26.

19,576. O. Imray.—From The Farbenfabriken vormals Meister, Lucius, and Brünig. Manufacture of a compound of antipyrine and iodine. September 16.

XXI.—PHOTOGRAPHIC PROCESSES AND MATERIALS.

APPLICATIONS.

13,964. H. Foster. The opaque negative photo-printer. August 19.

15,434. J. Hauff. The preparation and employment of aromatic amido-compounds as developing means in photography. September 11.

XXII.—EXPLOSIVES, MATCHES, Etc.

APPLICATIONS.

14,429. G. C. Dymond.—From E. Lagneau, Belgium. Improvements in or connected with the manufacture of matches, and in apparatus or machinery therefor. August 26.

15,217. A. L. Harrison. Improvements in time fuses. September 8.

15,456. J. V. Johnson. An improved match. September 12.

COMPLETE SPECIFICATIONS ACCEPTED

1890.

19,076. W. M. Mordey. Electric safety fuses. September 2.

1891.

9196. J. B. Scarlett. Manufacture of lucifer and other matches made of wood and cotton and other combustible and suitable material. August 26.

XXIII.—ANALYTICAL CHEMISTRY.

APPLICATION.

14,697. E. de Pass.—From F. Gossart, France. A method of analysing alcohols and other liquids or liquefiable bodies and apparatus therefor. August 31.

XXIV.—PATENTS UNCLASSIFIABLE.

14,371. F. C. Valentine.—From V. I. Gadesden, United States. Improvements in the treatment of a natural product to adapt it for various useful and ornamental purposes. August 25.

14,385. A. J. Boulton.—From A. Kuhne, Germany. A process of imparting a permanent colouring to turquoises and other precious stones. Complete Specification. August 25.

THE JOURNAL

OF THE

Society of Chemical Industry:

A MONTHLY RECORD

FOR ALL INTERESTED IN CHEMICAL MANUFACTURES.

No. 10.—Vol. X.]

OCTOBER 31, 1891.

[Non-Members 30/- per annum; Members
21/- per Set of extra or back numbers;
Single Copies (Members only) 2/6.]

The Society of Chemical Industry.

Past Presidents:

Sir H. E. Roscoe, M.P., LL.D., V.P.R.S.	1881—1882.
Sir Frederick Abel, C.B., D.C.L., F.R.S.	1882—1883.
Walter Weldon, F.R.S.	1883—1884.
W. H. Perkin, Ph.D., F.R.S.	1884—1885.
E. K. Muspratt	1885—1886.
David Howard	1886—1887.
Prof. James Dewar, F.R.S.	1887—1888.
Ludwig Mond, F.R.S.	1888—1889.
Sir Lowthian Bell, Bart., F.R.S.	1889—1890.
E. Rider Cook	1890—1891.

COUNCIL FOR YEAR ENDING JULY, 1892.

President: Prof. J. Emerson Reynolds, M.D., D.Sc., F.R.S.

Vice-Presidents:

Sir Lowthian Bell, Bart., F.R.S.	Ludwig Mond, F.R.S.
Wm. Crowder.	Dr. Hugo Müller, F.R.S.
James Duncan.	B. E. R. Newlands.
Dr. John Evans, F.R.S.	J. C. Stevenson, M.P.
David Howard.	A. Norman Tate.
S. H. Johnson.	Sir John Turney.

Ordinary Members of Council:

A. H. Allen.	E. K. Muspratt.
Arthur Boake.	T. L. Patterson.
Jno. Calderwood.	Boverton Redwood.
Dr. Charles Dreyfus.	Jno. Spiller.
H. Grimshaw.	T. W. Stuart.
Prof. R. Meldola, F.R.S.	William Thorp, B.Sc.

With the Chairmen and Secretaries of Sections.

Honorary Treasurer:

E. Rider Cook, East London Soapworks, Bow, E.

Honorary Foreign Secretary:

Dr. F. Hurter.

General Secretary: Charles G. Cresswell.

Offices:

Palace Chambers, 9, Bridge Street, Westminster, S.W.

NOTICES.

Foreign and Colonial Members are hereby advised that the subscription of 25s. for 1892, payable on January 1st next, should be sent in good time to the Treasurer in order to ensure continuity in the receipt of the Society's Journal. Any changes of address to appear in the new List of Members now in course of preparation should reach the General Secretary not later than January 15th, 1892.

Post Office Orders should be made payable at the General Post Office, London, to the Honorary Treasurer, E. Rider Cook, and should be forwarded to him at Bow, unless it be desired to notify a change of address.

Members who require extra sets or back numbers of the Journal are requested to make application to the General Secretary only, to whom also changes of address should be communicated.

Authors of communications read before the Society, or any of its Local Sections, are requested to take notice that under Rule 41 of the bye-laws, the Society has the right of

priority of publication for three months of all such papers. Infringement of this bye-law renders papers liable to be rejected by the Publication Committee, or ordered to be abstracted for the Journal, in which case no reprints can be furnished to the author.

Notice is hereby given, for the information of members and advertisers, that the advertisement columns of this Journal have been contracted for by Messrs. EYRE and SCOTT-WOODK, the Society's printers and publishers, to whom all communications respecting them should be addressed.

The Secretary is instructed to negotiate for the purchase of copies of the Society's Journal for January and May 1893, and January, February, and April 1896. Members possessing old copies of these numbers are particularly requested to communicate at once, stating price required, with Mr. Cresswell. The stock of all other numbers is at present sufficient for the Council's requirements.

LIST OF MEMBERS ELECTED, 23rd OCTOBER 1891.

Alcock, Jno. W., Central Brewery, Mott Street, Birmingham, brewer and maltster.
 Bahe, Arthur E., 81, Elswick Road, Lewisham, S.E., sanitary engineer.
 Baird, Wm., Donald's Chlorine Works, Kilwinning, N.B., technical chemist.
 Barratt, Alex., Brouhenlog, Glanvdon, Mostyn, North Wales, analytical chemist.
 Brown, J. Henry, Minas de San Domingos, Mertola, Portugal, technical chemist.
 Calkin, Wm. S., Johnsonburg, Quay P.O., Pa., U.S.A., paper and pulp manufacturing chemist.
 Catzian, Enrico, 81, Lombard Street, London, E.C., civil engineer.
 Chadwick, Walter M., Bergen Port Chemical Works, Bayonne City, N.J., U.S.A., manager.
 Chapp, Ralph E., c/o Standard Ammonia Co., Lim., Iceland Wharf, Old Ford, E., manager.
 Clements, Harry E., Broughton House, Upper Parkfields, Putney, S.W., chemical agent.
 Colwell, Walter F., Iceland Wharf, Old Ford, E., manufacturing chemist.
 Cooper, Harry J., Drinagh, Wexford, Ireland, cement manufacturer.
 Elson, Geo., 47, Faulkner Street, Manchester, drysalter and auctioneer.
 Frost, Robt., St. James' Chambers, Duke Street, London, S.W., barrister at law.
 Gadsdorthy, Frank, Grosvenor Road, Haddingley, Leeds, hbf. factor and tanner.
 Goodall, Reginald, Linden House, Highgate Road, N.W., mechanical engineering stationer.
 Hartley, Edw., 62, Wall Street, New York City, U.S.A., counsellor at law.
 Ingle, Herbert, Yorkshire College, Leeds, assistant lecturer on chemistry.
 Kathemer, Franz, Worms a Rhein Germany, technical chemist.
 Knochner, Henri, "Le Nidol," 43, Rue Lafayette, Paris, mining engineer.
 Lascelles, Jno. H., 23, Gros Church Lane, Leadenhall Street, E.C., chemist.
 McGeorge, A. J., 69, West 88th Street, New York City, U.S.A., analytical chemist.
 Mackenzie, Dr. G. S., Sydney Smelting Works, Pyrmont, Sydney, N.S.W., metallurgical chemist.
 Mackey, Wm. McD., Victoria Chambers, Leeds, analytical chemist.
 McSwiney, Eugene, 13, South Main Street, Cork, Ireland, manufacturing chemist.
 Pablon, A. M., c/o The Gaslight and Coke Co., Beckton, E., civil engineer.
 Pockock, Saml., Kalion Chemical Co., Philadelphia, Pa., U.S.A., technologist.

Pocklington, Hy., 41, Virginia Road, Leeds, Assurance Co.'s local manager.

Rutter, Chas. H., The Gas Company, Hove, Sussex, gas engineer.

Sankey, Chas. H., Essex Wharf, Canning Town, E., fireclay manufacturer.

Twitchell, E., The Emery Candle Co., Cincinnati, Ohio, U.S.A., technical chemist.

Vanderburgh, Dr. Horace C., Medical Department, University of City of New York, 410, East 26th Street, New York, U.S.A., chemist.

Walton, Fred., 4, Portugal Street, Lincoln's Inn, W.C., inventor and manufacturer.

Waterhouse, Robt., Earncliffe, Beech Hill Road, Sheffield, chemical student.

Wilding, Jas., jun., 7, St. Edmond's Road, Bootle, Liverpool, chemist.

Williams, Henry J., c/o Davenport and Williams, 161, Tremont Street, Boston, Mass., U.S.A., chemical engineer.

CHANGES OF ADDRESS.

Claus, C. F., jun., 10 Swansea; Ferryside, Carmarthen-shire.
 Coffey, J. E. H., 10 London; Hatherley Distillery, Pretoria, South African Republic.
 Cohen, Dr. J. B., 10 Manchester; Yorkshire College, Leeds.
 Dyson, Herbert, 10 Middlesbrough; Pooley Hall Colliery, Polesworth, near Tamworth.
 Frew, W., Journals to Theresienstrasse, 2/1, München, Bavaria.
 Gracey, Robt., 10 Fernlea; Fairecombe, The Barnfield, Exeter.
 Graham, J. A., 10 Green Laues; The Limes, Dunmow, Essex.
 Greville, H. L., Journals to Diersheim, Churchfields, Woodford, Essex.
 Griffith, D. Agnew, 10 Barnes; 2, Commercial Court, 17, Water Street, Liverpool.
 Hall, Edgar, 10 New South Wales; Albert Street, Brisbane, Queensland (Journals); and (subscription) c/o Geo. Bishop, 113, Powis Street, Woolwich, S.E.
 Hatschek, M., 10 Holborn; 3, Bedford Place, London, W.C.
 Herriot, Wm. Scott, 10 Glasgow; De Willem, Demerara, West Indies.
 Ingle, Harry, 10 Leeds; Universitäts Chemisches Laboratorium, Arcisstrasse, München, Bavaria.
 Kay, P., 10 Technical College; Lilymount, Heaton Road, Manningham, Bradford.
 Kershaw, J. B. C., 10 St. Helens; 24, Kirkstall Road, Telford Park, S.W.
 Laing, Jno., 10 East Preston Street; 30, Grange Road, Edinburgh.
 Lovett, W. Jesse, 10 Salford; 75, Clarendon Road, Crumpsall, Manchester.
 Marshall, Wm., 10 St. Andrews; (Journals) c/o D. G. Rose, Samarang, Java; and (subscription) c/o D. R. Calder Marshall, 49, Queen Street, Edinburgh.
 Marshall, Wm., 10 Nottingham; 34, Chatham Street, Edgeley, Stockport.
 Miller, Robt., Journals to c/o J. Carlile Miller, 9, Aeomb Street, Greenheys, Manchester.
 O'Beirne, W. G., 10 Queenboro'; 40, Gardner Street, Partick, Glasgow.
 Roberts, R. Wightwick. Journals to 22, Calle Arturo Prat, Valparaiso, Chili.
 Sanderson, T. C., Journals to Cerrilos, Santa Fé county, New Mexico, U.S.A.
 Schomer-Kestner, Dr. A., 10 Rue de Babylone; 8, Rue Pierre-Charron, Paris.
 Smith, Alf. L., 10 April Street; 7, Lothair Street, Nelson Street, Manchester.
 Starling, J. H., 10 Erith; 3, Victoria Road, Old Charlton, Kent.

Taylor, Malcolm, 1/o Birkenhead; c/o Quirk, Barton, and Burns, Lead Works, St. Helens.

Voeleker, Dr. L. A., 1/o Hanover Square; 20, Upper Phillimore Gardens, Kensington, W.

Zinkeisen, Dr. W., Journals to 508, New City Road, Glasgow.

CHANGE OF ADDRESS REQUIRED.

Littlejohn, J., 1 o 53, Renfield Street, Glasgow.

London Section.

CHEMICAL SOCIETY'S ROOMS, BURLINGTON HOUSE.

Chairman: T. Tyrer.

Vice-Chairman: W. Crowder.

Committee:

C. F. Cross.
J. Dewar.
A. G. Green.
S. Hall.
C. W. Heaton.
J. Heron.
D. Howard.

W. Kellner.
B. Redwood.
W. S. Squire.
G. N. Stoker.
F. Napier Sutton.
Wm. Thorp.
T. E. Thorpe.

Hon. Local Secretary: Thos. W. B. Mumford.

Communications to be sent to T. Tyrer, Stirling Chemical Works, Abbey Lane, Stratford, E.

SESSION 1891-92.

1891:—

Nov. 2nd (Monday):—

Mr. W. C. Young, "On Volatile Organic Matter in Potable Water and a simple Method of Estimating Volatile and Non-Volatile Matter in Water."

Dr. S. Rideal, "Some Experiments on Solidifying Petroleum."

Dec. 7th:—

Mr. Watson Smith, "A Contribution to our Knowledge of the Soluble and Resinoid Constituents of Bituminous Coals."

Dr. Murray Thompson, "The Salt Industry of India."

1892:—

Jan. 4th—Mr. Beverton Redwood, "The Gallician Petroleum and Ozokerit Industries."

Glasgow and Scottish Section.

Chairman: E. C. C. Stanford.

Vice-Chairman: A. Crum Brown.

Committee:

J. Christie.
W. J. A. Donald.
D. B. Dott.
C. J. Ellis.
C. A. Fawsitt.

PATENT.

Improvements in Apparatus for Evaporating, Concentrating, and Distilling Liquids. R. A. Robertson and D. Ballingall, Glasgow. Eng. Pat. 15,698, October 4, 1890. 11d.

THE object of this invention is the economical heating of the liquid treated in multiple-effect distilling apparatus before it enters the first "effect" of the system. For this purpose the fresh liquid is passed through tubes or coils exposed to the heat of the liquid under treatment in the last effect, or to the vapour given off from that liquid. From the last effect the liquid is passed through similar apparatus in the second last effect, and so on until it has been passed through and received the last increment of heat from the liquid in the first effect, into which it is then fed for treatment. The drawings accompanying the specification show three different arrangements for effecting this purpose, and there are two claims.—11.

* Any of these specifications may be obtained by post, by remitting the cost price, *plus* postage, to Mr. H. Reader Lack, Comptroller of the Patent Office, Southampton Buildings, Chancery Lane, London, W.C. The amount of postage may be calculated as follows:—

If the price does not exceed 8d.	1/11.
Above 8d., and not exceeding 1s. 6d.	1d.
" 1s. 6d., " " 2s. 4d.	1 1/2d.
" 2s. 4d., " " 3s. 4d.	2d.

Improvements in or connected with Apparatus for Making Fresh Water from Salt Water. T. Hocking, Bootle. Eng. Pat. 16,232, October 13, 1890. 11d.

This invention relates mainly to that kind of apparatus in which the salt water is heated by steam, which is separated from it by metal walls, the steam being subsequently condensed. Instead of being heated in bulk, as usual, the salt water is broken up into thin streams or drops, and in this state caused to flow over the metallic heating surface, which may be of any suitable form, a convenient one being that of a tube or cylinder, or a spirally coiled tube, and in so doing is quickly converted into steam. The water may fall by its own gravity on to the heating surface, or this latter may be made to move and take up salt water in comparatively small and divided thin layers, or in drops, and in such quantities that all the water is not evaporated, but a residue of strong brine remains and passes away into a receptacle, and can be afterwards further concentrated if desired. The heating surface is all placed within a case, with which it is connected by suitable pipes having apertures for the passage of the heating fluid, and which convey it in the manner described in Eng. Pat. 16,452 of 1889. For details of construction and mode of working, the specification and three sheets of drawings accompanying it must be consulted. There are eight claims.—E. S.

Improvements in Apparatus for Drying Semi-Liquid, Granular, or Pulverulent Substances. J. Dunn, Kelso. Eng. Pat. 16,384, October 15, 1890. 8d.

A vertical cylindrical vessel, made in two parts, has a vacuum maintained in it by a pump. In the upper part, constructed of iron or steel plates, are arranged rotating discs, all or some of which are heated by steam admitted through the hollow vertical shaft upon which they are fixed. The discs are of two kinds, of different diameters, and placed alternately, such that the substances to be dried, and which are fed in at the top of the vessel, are moved inwards and outwards by means of stationary inclined blades, the substances when moved inwards descending through a central opening in the next lower disc, and when moved outwards descending over the outer edge of the disc to the next lower disc. The lower part of the vessel, made of cast iron, is heated by steam admitted into recesses under the bottom, and has rotating stirrers arranged within it. The materials are allowed to accumulate to any suitable depth in the lower part of the vessel, when they are subjected to the final drying action of the steam in the recesses, and afterwards discharged into a chuted arrangement so as to prevent any ingress of air whilst the materials are being transferred to its under delivery side.—E. S.

Improvements in Apparatus for Evaporating, Distilling, or Concentrating Liquids. L. F. Wilson, Lille, France. Eng. Pat. 16,285, October 17, 1890. 8d.

This invention relates to apparatus in which steam or other heating agent is applied to the evaporation of liquids, which are spread in thin layers over extended surfaces so as to be more rapidly and thoroughly acted upon by it. The apparatus, as claimed, consists of two thin corrugated sheets of a conducting metal, copper preferred, fixed back to back, with the ridges and furrows of their corrugations straight and horizontal, leaving the spaces between them supplied with the heating medium, while the liquid to be treated flows in a thin layer down the outside.—E. S.

An Improvement in Feeding Apparatus for Filters. R. Morris, Blackheath. Eng. Pat. 16,616, October 18, 1890. 6d.

A valve-cock and float are provided to feed the upper part of the filter. The lower part containing the filtered water is also supplied with a float, from which a rod extends upwards immediately under the lever of the upper float. The filtered water, having reached a determined height, the

float and rod are raised, and prevent the upper float from descending, and thus cuts off the supply of water. By this means the over supply of water to the filter is obviated, and the filtering material can be aerated.—E. S.

Improvements in Filtering Machinery. E. Martin, Watford. Eng. Pat. 6186, April 10, 1891. 11d.

An endless travelling band made of any material suitable for filtering purposes is so arranged as to assume for a portion of its length the form of an open horizontal shallow trough or cistern. For this purpose the band is mounted in a manner to cause it to make a slight descent at one end, and simultaneously to have the two sides or edges of the fabric turned up. In this form the band extends horizontally for a certain length, and is then made to rise again on an incline and to spread out flat. In this manner a shallow travelling cistern is formed between the two inclines wherein the water for filtering is received. The speed of the travelling bed may be regulated in such a way as to allow it to be coated to any desired degree with matter arrested from the filtered liquid, and on continuing to travel it may be conducted through cleansing apparatus, whence it will return cleaned and ready for the renewal of the operation. The specification and drawings indicate various arrangements for the purpose, but there is only one claim made.—B.

Improvements in Filters. W. P. Thompson, Liverpool. From J. A. Bowden, Detroit, U.S.A. Eng. Pat. 9311, June 2, 1891. 8d.

The improvements consist (1) in preventing the weight of the filter-bed coming directly on to the outlet strainer; (2) in securing a more thorough cleaning of the filter-bed; (3) in simplifying the general operations. For the means by which these are effected the specification must be consulted. There are nine claims.—E. S.

Improvements in Filtering Apparatus. W. P. Thompson, Liverpool. From J. A. Bowden, Detroit, U.S.A. Eng. Pat. 9311, June 2, 1891. 8d.

This invention is intended to produce a filter capable of filtering with rapidity a large body of water, and also for rapidly cleaning the filter-bed. For the mode by which it is proposed to effect this, and for details of construction, the specification and four sheets of drawings attached to it must be consulted. The patentee claims, 1st: "In a filter, the combination with its case of a water inlet pipe, at its top a horizontal perforated wash pipe at the bottom of the filter bed, a shield beneath the latter, and a horizontal strainer beneath the shield . . ." There are eight claims.—E. S.

Improvements in Centrifugal Apparatus for Testing Relative Volumes of Mixtures of Liquids of Different Specific Gravities. J. Laidlaw, Glasgow. Eng. Pat. 10,492, June 20, 1891. 6d.

The object of this invention is to prevent the tendency of the testing bottles being burst by the pressure of the contained fluid arising from centrifugal action. To effect this a revolving disc has pockets for holding the testing bottles, whilst the centre of the disc forms a trough for holding water or other liquid of suitable density, which is caused by centrifugal action to flow over the edge of the trough and into the pockets, and to surround the bottles. The pressure of the liquids inside and outside the bottles being equalised, the liability of their being burst by a high rate of speed is greatly reduced.—E. S.

Improvements in Condensing or Liquefying Vapours or Gases and in Apparatus therefor. J. Gamgee, Wimbledon. Eng. Pat. 10,374, July 4 1890. (Under Internat. Cour. December 9, 1889.) 8d.

This invention claims to embody a novel method of condensing steam or vapour, in causing it to be incorporated

NOVEL CONDENSING APPARATUS.

and mixed intimately with a certain fixed quantity of water or other liquid which is violently agitated by the vapour itself. The liquefaction is caused by forcing the vapour to perform work in overcoming the resistance of columns of liquid in its passage to the receiver of the condensed product. In the case of exhaust steam from a motor, a vacuum is maintained above the liquid columns through which the steam has to pass, in order to facilitate its escape from the motor. The accompanying illustration shows the apparatus as arranged for that purpose.

A is a vessel fitted with concentric cylinders or pipes B B, which are connected alternately to the top and bottom plates of the vessel A, so as to form a continuous, annular up-and-down passage of diminishing area from the outer to the inner pipe B. The inner pipe reaches into the chamber C above, whilst the lower end of the outer pipe B is provided with a number of nozzles D, communicating with the steam chamber E, which receives the exhaust steam from the motor through the pipe G. The top of each nozzle is closed with a small check valve opening upwards. The vessel A and chamber C having been filled with water up to and covering the upper edge of the inner pipe B, the steam is passed through the nozzles D and overcomes the resistance of the water, aided by the vacuum produced in the chamber C through the pipe K. The branch-pipes H with check-valves return the water from C to A, and thus a vigorous circulation is set up through the whole apparatus. The pipe I carries away the surplus hot water, representing the steam condensed in the apparatus.

A similar arrangement can be employed without vacuum in the process of the distillation of essences or for other similar purposes. When so applied, all losses of valuable vapours are avoided owing to the whole apparatus being hermetically sealed to the outer atmosphere. There are five claims and two sheets of drawings.—B.

Improvements in Filters and in the Method of and Means for Cleansing Filtering Surfaces. P. M. Justice, London. From "The Automatic Filter Company," Washington, U.S.A. Eng. Pat. 11,594, July 8, 1891. 8d.

The object of this invention is the automatic removal of impurities deposited by water on stationary filtering surfaces. The removal is effected by means of a solid body of sand which is passed slowly across and in contact with those surfaces, whilst the current of water through the filtering medium is periodically reversed with a view to loosening the impurities thereon. The simplest form of filter constructed on these lines is shown by the accompanying illustration.

AN IMPROVED FILTER.

In the figure A is the outer vessel, 3 the porous filtering tube, Y the filling of sand, 4, 5, a circulating tube with an injector tube 6 at the lower corner, through which the filtering water is admitted. The current created by the injected water draws sand from below and re-deposits it on the top of the body of sand, and the impurities attached to the sand during its descent are swept off in its passage through the pipe 4, and are led out of the filter through the pipe 8. The tube 9 leads to a small hand pump I, which is used from time to time for creating a surplus pressure in the tube 3, thereby reversing the current and loosening the impurities, which are then carried away by the descending sand. The specification covers 20 claims, and the drawings show various modifications and combinations.—B.

Improvements in or relating to the Refrigerating Medium employed in Freezing and similar Machines. W. McLaren, Liverpool, and P. Holmes, London. Eng. Pat. 12,111, July 16, 1891. 4d.

For the purpose of detecting any leakage of carbonic acid from the refrigerator, the patentees impart to the carbonic acid a pungent smell by the addition of peppermint or similar substance.—H. A.

Improvements in Filters. J. Haslam, Tonge. Eng. Pat. 12,512, July 23, 1891. 6d.

This patent relates more particularly to the construction of portable filters and to their tube joints, and embraces the use of internal partitions or shelves which project from alternate sides and hold the filtering material between them, the object being to lengthen the passage of water through the filter. There are 12 figures and three claims.—B.

II.—FUEL, GAS, AND LIGHT.

PATENTS.

Manufacture of Illuminating Gas and other Useful Products from Refuse of the Kind known as Town's Refuse. F. Sandler, London. Eng. Pat. 10,313, July 3, 1890. *Id.*

See under XVIII. B., page 845.

Improvements in the Manufacture of Artificial Fuel. W. R. Lacey, Brentford. Eng. Pat. 11,514, July 23, 1890. *Id.*

Various mixtures for forming blocks of artificial fuel are given, of which the following is one that will serve as an example: "Charcoal powder and a soluble silicate are mixed together by simply stirring, to which is added calcium hydrate and a small proportion of freshly precipitated alumina or magnesia. The calcium hydrate is in chemical excess in order that a sufficiency (or ignition) shall remain free to absorb or combine with the carbonic acid. The entire mass after mixing is merely poured into a mould and allowed to set. The best proportions are these:—enough soluble silicate (preferably sodium silicate) is taken to well wet the charcoal. Then about one-fifth calcium hydrate is mixed in together with 1 or 2 per cent. of freshly precipitated alumina or magnesia."—H. S. K.

Improvements in the Treatment of Tar and Pitch. W. H. Nevill, Farnside. Eng. Pat. 13,398, August 26, 1890. *Id.*

Pitch made from wood or other vegetable matter, or paper (probably the coarser or brown qualities) which has been steamed and desintegrated is mixed in the proportion of 1 or 2 per cent. with tar or a mixture of tar and pitch, and the mixture is heated for several hours with frequent stirring. "It may then be used with advantage in the manufacture of patent fuel, for road making, and for various other purposes."—H. S. K.

Improvements in the Treatment of Sludge. A. O. Jones, Harrogate, and S. Fox, New Wortley. Eng. Pat. 11,253, September 10, 1890. *Id.*

See under XVIII. B., page 846.

Improved Method of and Apparatus for Producing Gas from Bituminous Fuel. F. E. Ross, Croydon. Eng. Pat. 16,846. October 22, 1890. *Id.*

The apparatus described in this patent is employed for the production of carburized hydrogen or gaseous hydrocarbons, and producer gas, from bituminous fuel: the process is carried out in such a manner as to avoid the formation of clinker, and at such a temperature that the gas is free from any considerable quantity of readily condensable vapours.

The fuel is placed in a gas producer and distilled from above by heat developed by the combustion of gaseous fuel, which is forced into the upper part of the producer, together with a suitable quantity of air. The products of distillation pass downwards through the incandescent coke resulting from coal previously carburized, and in this way the condensable hydrocarbons are decomposed, and the carbonic anhydride is converted into carbonic oxide. The gas employed for heating the fuel is drawn off directly from the bottom of the producer.—F. S. K.

Improvements in the Manufacture of Hydrogen Gas or a Mixture of Hydrogen and Carbon Monoxide, and Apparatus therefor. V. B. Lewes, Greenwich. Eng. Pat. 20,752, December 19, 1890. *Id.*

A RETORT, partly filled with iron borings, or with a mixture of iron and carbonaceous material, or with asbestos containing iron in a very fine state of division (see Eng. Pat. 4134 of 1891; following abstract) is placed in the centre of a gas producer which is charged with carbonaceous material and lighted from the bottom; by means of an air blast the fuel is raised to a bright red heat and then a little steam is admitted together with the air. The gaseous mixture of carbonic oxide, nitrogen, and hydrogen produced in this way is led from the top of the producer down through the retort, and then away; as soon as the iron oxide in the retort is completely reduced, and the requisite temperature has been attained, the producer-gas is turned off and steam, previously heated in the producer, is passed over the iron, the hydrogen being led away to a gasometer. The process is then repeated as described.

The advantages claimed for this form of apparatus are: 1. The iron can be used over and over again. 2. The rapid cooling of the iron during the decomposition of the steam is prevented.—F. S. K.

Improvements in or Appertaining to the Manufacture or Production of Hydrogen. V. B. Lewes, Greenwich. Eng. Pat. 4131, March 7, 1891. *Id.*

THE PATENTEE claims the use of a mixture of carbonic oxide, nitrogen and hydrogen, for the reduction of oxide of iron in the process described in Eng. Pat. 20,752 of 1890 (see preceding abstract). This gaseous mixture is a far better reducing agent than carbonic oxide, and is easily obtained in the manner already stated.

The finely-divided iron employed for the production of hydrogen is prepared by saturating asbestos or pumice with certain iron salts, which are easily decomposed into oxide of iron on heating, or by mixing moist hydrated oxide of iron with asbestos fibre and iron filings.—F. S. K.

Improvements in Apparatus for Burning Liquid Hydrocarbons. W. L. Wise, London. From "The Aërated Fuel Company," Springfield, U.S.A. Eng. Pat. 5020, March 20, 1891. *Id.*

THE INVENTION comprises an apparatus consisting essentially of an oil tank, from which the oil is forced by an air compressor to a burner or series of burners, the same compressor also giving a supply of air to the burners. There is also a special form of nozzle-burner, of which more than one modification is described, fitted with arrangements for regulating the feed of oil and air to the burner. Drawings accompany the specification.—H. S. P.

An Improvement in Incandescent Illumination and Apparatus for that Purpose. J. Moeller, London. Eng. Pat. 5022, March 20, 1891. *Id.*

THIS INVENTION relates to the production of a gas, suitable for use in incandescent lamps, in situations where coal-gas is not available. For this purpose a current of air, obtained by means of bellows, or by means of a rotating drum partitioned like that of a gas meter, and partly immersed in water, is passed through "benzoline" or through fibrous material soaked in "benzoline"; the gaseous mixture obtained in this way is burnt in a Bunsen burner, and heats to incandescence a hood or mantle of refractory metallic oxide.—F. S. K.

Improvements in and in Apparatus for the Manufacture of Crude Peat into Fuel. A. A. Dickson, Quebec, Canada. Eng. Pat. 7983, May 9, 1891. 8d.

This is an improved process for the conversion of crude peat into good fuel, the object of the invention being, more especially, to dry the material, as it comes from the bog, without causing any deterioration in its fibrous condition and without the aid of artificial heat.

The crude peat is first compressed in a conical screw conveyor and compressor, and then between rollers covered with some absorbent material such as felt, until most of the water is removed. It is then agitated in a heated cylinder or chamber, where it is at the same time exposed to a blast of air. The dry material is finally ground to a powder, and the sifted powder compressed into blocks.

The apparatus required is shown in two sheets of drawings.—F. S. K.

Process of Utilising the Waste of Distilleries, Breweries, Glucose and Starch Works and the like for the Preparation of Fuel. A. Parks, Martinsburg, U.S.A. Eng. Pat. 8893, May 26, 1891. 6d.

See under XVII., page 844.

Improvements in and relating to Incandescent Gas Burners. A. J. Boulton, London. From J. C. O. Chemin, Paris, France. Eng. Pat. 9240, June 1, 1891. 8d.

THE object of the improved burner is to enable ordinary coal gas, or other gas, under low pressure, to be used in incandescent lamps. This is effected by placing round the gas jet a number of superposed porcelain or metal truncated cones, between which air sufficient for combustion is drawn; in the uppermost cone there is placed a piece of wire gauze which acts as a mixer. The gaseous mixture burns on the outer surface of a cap or dome, made of platinum, magnesium oxide, or other suitable material, and fixed on the top of the uppermost cone; the whole is surrounded by an ordinary chimney.—F. S. K.

An Improved Compound for Treating Fuel. H. H. Lake, London. From The Standard Coal and Fuel Company, Boston, U.S.A. Eng. Pat. 9796, June 9, 1891. 4d.

A MIXTURE of the following substances is made:—

	Parts by Weight.
Saltpetre (nitre or preferably Chili saltpetre).....	25
Common salt as free from moisture as possible.....	50
Sodium sulphate (Glauber's salt, or preferably "salt cake").	15
Carbonate of soda (or soda crystals).....	5
Sal-ammoniac.....	5

"The above ingredients should be dried, ground, and thoroughly mixed together, and will form a mixture which does not deliquesce under ordinary climatic conditions, and consequently may be stored and shipped in a dry condition without necessitating the use of air-tight packing cases." The powder may be either sprinkled upon the coal or other fuel, or preferably a solution of it in water may be made and sprinkled over the fuel, to assist the combustion of the fuel.—H. S. P.

III.—DESTRUCTIVE DISTILLATION, TAR PRODUCTS, Etc.

Constitution of the Oxygen Compounds in Petroleum. R. Zoloziecki. Ber. 1891, 24, 1808—1815.

AFTER referring briefly to the work of previous investigators, the author gives an account of the acids obtained from petroleum in a works at Kolema, which were sent to him in the form of sodium salts by H. Wisniowski. These were separated from the petroleum still present therein by repeated treatment with alkalis and reprecipitation by mineral acids, a large quantity of a dark brown oil being eventually obtained. This was dissolved in alcohol, the solution subjected to the action of hydrochloric acid gas, and the mixture of ethyl salts thus obtained submitted to fractional distillation.

The following fractions were obtained:—

Fraction.	Boiling Point.	Carbon.	Hydrogen.
1	220—225	72.05	11.37
		71.91	11.63
2	225—230	72.60	11.52
3	230—235	73.08	11.56
		73.25	11.81
4	235—240	72.66	11.33
		73.32	11.48
5	240—245	73.65	11.62
6	245—250	73.86	11.75
7	250—260	74.20	12.05

Fraction (2) corresponding to the ether of the formula $C_{10}H_{18}O_2$, fractions (3) and (4) corresponding to $C_{11}H_{20}O_2$, and (6) and (7) corresponding to $C_{11}H_{20}O_2$, appear to be approximately of the same character and yield the corresponding acids on hydrolysis. From the analysis of both acids and ethyl salts it would appear that the former have the composition $C_{10}H_{18}O_2$, $C_{11}H_{20}O_2$ and $C_{12}H_{22}O_2$ respectively, and therefore belong to a series having the general formula $C_nH_{2n-2}O_2$, which is in conformity with the results obtained by previous authors.

With regard to the condition of these acids, the author, after an exhaustive investigation, found that on treating the acid fraction $C_{10}H_{18}O_2$ with iodine and phosphorus, an iodine compound was obtained having the formula $C_{10}H_{17}IO$ and not $C_{10}H_{17}IO_2$. This result precludes the presence of a carboxyl group supposed to exist, and the author concludes that these compounds are lacto-alcohols. For the compounds $C_{10}H_{18}O_2$ he gives the following constitutional formula:—

In conclusion, it is stated that although these acids exist in petroleum in small quantities, their presence is of importance in the purification of petroleum, a circumstance which the author intends to discuss on a future occasion.

—D. B.

The Pierce Process for the Production of Charcoal, Wood Alcohol, and Acetic Acid. W. L. Dudley. J. Analyt. and Applied Chem. May 1891.

THE special advantages of this process, which was devised in its original form in 1876, consist in the larger yield of charcoal which is obtained from the wood carbonised, and in the far smaller loss of by-products, the charcoal being also of better quality than any otherwise prepared. The

average amount of charcoal obtained by the other processes is 17.5 per cent. of the wood employed, while the yield in this case is shown in the table:—

	Per Cent.
Charcoal.....	25.30
Methylalcohol.....	0.75
Acetic acid.....	1.00
Tar.....	1.00
Water.....	45.95
Percentage.....	23.00
	100.00

The wood is heated in brick kilns, shaped like a bee-hive of 22 feet diameter, and 16 feet height in the centre, by means of the combustion of the permanent gases produced during a previous operation. During the drying, the steam is allowed to escape through a hole in the top of the kiln, but when the carbonisation begins, the hole is stopped up, and the products of distillation are drawn away by an exhaust fan into a large main leading into a series of condensers, where the acetic acid, tar, and alcohol are deposited. The uncondensed gases are then forced back into the kilns, where they are mixed with the requisite amount of air, by means of a steam jet, and burned in the furnaces. In this way, the carbonic acid gas and the water vapour being decomposed into carbonic oxide and hydrogen respectively, more gas is accumulated than is needed for carbonising, and in fact more than sufficient to yield steam for the engines driving the fans, &c., and for the stills in the alcohol house. The liquor from the condensers is allowed to stand in tanks, and when the tar has subsided, it is drawn off and neutralised with milk of lime. The neutral liquor is distilled in wooden stills by dry steam to obtain the alcohol, which is afterwards twice rectified, and the residue is evaporated and the crude calcium acetate sold as such. The tar is chiefly employed in painting the gas mains, condensers, &c.

A complete plant on this system consists of 48 kilns, which hold 55 cords of wood each, and take from 1² to 18 hours for drying, and six to eight days for carbonising. The kilns are set in three batteries of 16 each, each battery having its own fan and set of five condensers in series, the fan being placed after the first condenser. These are wooden boxes about 4 feet square and 14 feet long, filled with copper tubes, in which the condensing water circulates. The alcohol house contains eight "primary" stills, for the first distillation, four "intermediate," and two "shipping" stills. Of these, the primary are made of wood, the others being of sheet iron, and fitted with a weak liquor condenser, consisting of a worm passing through a trough filled with water at a temperature of 80–95° F. to strengthen the alcohol as much as possible. The alcohol having to pass through two of these baths, often becomes of as much as 70 per cent. strength, in which case it is diluted with water to 82 per cent. for shipment.—L. H. L.

Ohio Petroleum.—J. and A. Mandel and A. Bourgeois. J. Amer. Chem. Soc. 13, 168–169.

Two petroleum from Lima, Ohio, is dark green in colour, and very mobile, specific gravity at 15° = 0.791. The authors did not observe that peculiar objectionable odour which crude oil pumped from the oil-fields of Ohio is said to possess, and the various fractions had the same smell as the corresponding fractions from Pennsylvania petroleum. The naphtha was easily refined by means of sulphuric acid and washing. The burning oil, purified in the usual way by means of sulphuric acid, caustic soda, and washing, was colourless and nonfluorescent. On fractionation the oil yielded 16 per cent. of naphtha of 70 B., 65 per cent. of burning oil, 6 per cent. of paraffin oil, and 10 per cent. of residue. Distillation began at 24° owing to the large amount of naphtha present, but when 60 per cent. had passed over, the temperature was 310° beyond the

point the specific gravity and boiling point of the distillate decreased, the extremes of specific gravity of the fractions being 0.680 and 0.830.—C. H. B.

Some Crude Petroleums.—D. Woodman. J. Amer. Chem. Soc. 1891, 13, 179–181.

DISTILLATIONS were performed of three samples of petroleum: one was a sample of crude oil from California, specific gravity at 15.5° C. = 0.835, colour dark brown, opaque, no appearance of fluorescence except on dilution, odour peculiar and different from the under-mentioned samples, not being so disagreeable. A second sample was crude oil from the Lima (Ohio) field, specific gravity at 15.5° C. = 0.835, colour brown, slight fluorescence, odour peculiar and disagreeable. A third sample was likewise from the Lima field, its specific gravity was 0.850, in appearance and odour, however, it did not differ from the preceding.

Tables of specific gravities of the various fractions are given, the approximate classification in percentages being as follows:—

	California.	Lima No. 1.
Naphtha under 0.73 sp. gr.	10	10
Illuminating oil.....	40	50
"Lubricating" oils.....	40	30
Residuum.....	10	10

The California oil contained:—

Sulphur (Carius method).....	0.18
Sulphuric acid (oil washed and washings, re-presented by BaCl_2).....	0.0003
Water.....	0.27

The oil remained perfectly fluid at -32°C. , the viscosity at that temperature being apparently equal to that of boiled linseed oil; the heaviest distillates solidified at -18°C.

The second sample of Lima oil gave:—

	Per Cent.
Naphtha and burning oil.....	56.8
Heavy oils.....	32.0
Residuum.....	9.6
Water.....	0.7
Sulphur.....	0.65

Notwithstanding the strong odour of the Lima oil, it rarely contains as much as 1 per cent. of sulphur. Analyses of samples of crude Ohio oils from different localities have given, on the average, about 0.50 per cent. of sulphur (Mahery and Smith, Amer. Chem. J. 13, 234). The removal of the sulphur compounds, or the destruction of those accountable for the disagreeable odour in Lima oil is a problem still open for a satisfactory solution.—T. L. B.

The Formation of Inactive Tartaric Acid by the Oxidation of Phenol with Potassium Permanganate.—O. Doebner. Ber. 1891, 24, 1753–1757.

Phthaleins. R. Meyer. Ber. 1891, 24, 1412—1418.

ACCORDING to the view advanced some time ago by the author (this Journal, 1889, 116) fluorescein contains the ring—

composed of one oxygen and five carbon atoms, and he believes this ring to be an essential character of the phthaleins of the fluorescein type and that these owe their tinctorial and fluorescent properties to this grouping. This ring is formed when the so-called methane carbon atom takes up an ortho-position to hydroxyl groups in the two phenol nuclei. In accordance with this view, phenols such as α -naphthol in which the para-position to the OH group is free, should yield true phthaleins, whilst phenols such as β -naphthol, which cannot give para-substitution products, might be expected to yield phthalein anhydrides containing the above ring. The author has treated both α - and β -naphthol with phthalyl chloride and finds that the former yields a true phthalein as previously shown by Grabowski (Ber. 4, 725), whilst β -naphthol yields the anhydride—

as expected. This crystallises in rhombic plates or needles melting at 115°—117°. Its solution in concentrated sulphuric acid exhibits an intense reddish-yellow fluorescence. When it is boiled with alcoholic potash it yields a substance crystallising in slender colourless needles; this is nearly insoluble in boiling alcohol, readily soluble in water, and is probably the potassium salt of—

Phenolphthalein anhydride in all probability belongs to the same class of phthaleins and should accordingly be represented by the formula—

The author has examined residues obtained in the manufacture of phenolphthalein and in one sample found nearly 44 per cent. phenolphthalein anhydride. The purified anhydride dissolves in concentrated sulphuric acid and the solution exhibits a yellow colour and an intense green fluorescence. It crystallises from alcohol in long and broad lustrous needles containing water of crystallisation, and when dried at 130° has the composition $(\text{C}_{20}\text{H}_{12}\text{O}_3)_x$. It melts at 180° and not at 173°—175° as stated by Baeyer.

When it is boiled with alcoholic potash it is apparently converted into the unstable acid—

the solution obtained is no longer precipitated by the addition of water, but if the alcohol be driven off from the diluted solution, some anhydride forms and separates and the remainder can be thrown down as anhydride by the addition of hydrochloric acid.—A. K. M.

Synthesis of Indigodisulphonic Acid (Indigo-carmin).

B. Heymann. Ber. 1891, 24, 1476—1478.

It has been shown by Heuman and others (this Journal, 1890, 1121) that when phenylglycocine is fused with caustic potash a leuco-compound is obtained which yields indigo on oxidation. The reaction could not be induced by other reagents, such as zinc chloride or concentrated sulphuric acid. The author finds, however, that the condensation is readily effected when fuming sulphuric acid is employed, but that in this case indigodisulphonic acid is produced. The reaction is best conducted as follows:—One part of phenylglycocine is mixed with 10—20 parts of sand, and the mixture added to 20 parts of fuming sulphuric acid (containing 80 per cent. anhydride) at a temperature of 20°—25°, and the temperature is not allowed to rise above 30°. The glycocine dissolves readily to a yellow solution, but on adding concentrated sulphuric acid sulphur dioxide is evolved, and the solution assumes the deep blue colour of indigo. Ice is then added to the product and the indigo-carmin precipitated by the addition of salt. This synthetic indigo carmin produces purer shades than the best natural indigo of commerce.

In explanation of the above reaction, it is assumed that possibly the sulphonic acid of indoxyl sulphate is first formed, and that this undergoes the following change when the concentrated sulphuric acid is added:—

The yield of indigo-carmin amounts to about 60 per cent. of the phenylglycocine employed. (See also this Journal, 1891, 758.)—A. K. M.

Azonium Bases. O. N. Witt. Ber. 1891, 24, 1511.

THE reaction recently described by Kehrman and Messinger for the synthesis of azonium bases (Ber. 24, 1239) was discovered by the author in 1887 (this Journal, 1887, 543).—A. K. M.

On Triquinylmethane. E. Nölting and C. Schwartz. Ber. 1891, 24, 1606—1609.

THIS compound can be obtained either from paraleuco-aniline or from pararosaniline in the following manner. A mixture of 22 grms. of pararosaniline, 64 grms. of glycerol, 52 grms. of sulphuric acid, and 7 grms. of 4-picric acid are heated for 3—4 hours to 140°—150° C. until all the rosaniline has disappeared. After purification (preparation of the free base by precipitation with carbonate of soda at a low temperature, and by its crystallisation from benzene after resinous matters have been removed by

addition of petroleum spirit), the base was obtained in white needles melting at 202° C. On oxidation with the theoretical quantity of potassium bichromate and acetic acid the triquinylmethane—

yields the triquinylcarbinol—

white needles melting at 108° C., forming salts. But no colouring matters could be obtained from either body.

Diquinylketone—

was prepared by heating 10 grms. of diamidobenzophenone, 29 grms. of glycerol, and 3 grms. of picric acid for about 4 hours to 140–150° C. After purification it forms colourless needles, easily soluble in alcohol, with difficulty in boiling water, and melting at 174° C.—A. L.

On Nitro-Derivatives of Alizarin and Purpurin. R. Brash. Ber. 1891, 24, 1610–1619.

Diacetyl-α-Nitroalizarin.—One part by weight of diacetylalizarin is gradually added to 2 parts of colourless nitric acid sp. gr. 1.5, care being taken that the temperature does not rise above 0° C. One part of nitric acid is then added to the mixture and it is poured into ice-water as soon as a sample in an alcoholic alkaline solution ceases to show the alizarin spectrum. The diacetyl-α-nitroalizarin crystallises from glacial acetic acid in light yellow needles melting at 194–195.5° C. Sodium carbonate saponifies it at ordinary temperatures; mordanted cotton is gradually dyed by it, though boiling water does not seem to have any saponifying action on it.

α-Nitroalizarin, which was first prepared by Perkin and then examined by Schueck and Romer, was obtained by saponifying the acetyl compound. It crystallises from glacial acetic acid in brownish-yellow needles melting with evolution of gas at 289° C.

Amidoalizarin was first obtained by Perkin by the reduction of a nitroalizarin by sodium amalgam. Schueck and Romer prepared it by treating a solution of a nitroalizarin in ammonia with sulphuretted hydrogen. After precipitation with hydrochloric acid and purification from sulphur with carbon bisulphide, the body was recrystallised from glacial acetic acid and obtained in dark brown plates with a yellowish-green lustre. On treating an acid solution of an amidoalizarin with nitrous acid and boiling it after diazotisation, purpurin is formed. If, however, the diazo-compound be rendered alkaline, alizarin is obtained after extraction with ether. Diazoalizarin does not combine with phenols. *β*-Amidoalizarin does not yield purpurin after diazotisation but alizarin, and Ankerh's statement to the contrary must be due to a mistake.

Pseudo-Nitropurpurin is obtained by mixing alizarin with so much fuming nitric acid that a thin paste is formed. The mixture is poured out to ice, diluted, and washed with water until neutral. As soon as the acid disappears the yellow compound is dissolved by the water with a dark red colour, a sign that the pseudo-nitropurpurin is changed into nitropurpurin. The dry pseudo-compound is of a light yellow colour and can be kept; the moist body, however, changes

easily into the nitropurpurin. The two compounds are isomerides, the pseudo-nitropurpurin, perhaps, having a constitution represented by one of the two following formulæ:—

or

Pseudo-nitropurpurin dissolves in a solution of carbonate of soda with a brownish-yellow colour, changing on heating to a red, a sign that it is converted into nitropurpurin.

Nitropurpurin is prepared in the manner before described and contains the nitro group in the meta-position, whilst the hydroxy groups occupy the positions 1:2:4. It resembles purpurin and dyes fibres mordanted with chrome, iron, or chromium salts nearly the same shades as purpurin does. Its solution in alum does not show any fluorescence; its solution in concentrated sulphuric acid is yellowish red, whilst the solution of purpurin in the same solvent is carmine-red. The nitration of purpurin produces the same results as the nitration of alizarin, namely pseudo-nitropurpurin and nitropurpurin.

β-Nitroalizarin when heated at ordinary temperature with 7 parts of nitric acid, sp. gr. 1.5, is changed into pseudo-nitropurpurin.

Perkin observed on nitrating diacetylalizarin the formation of a deep-red compound besides α-nitroalizarin. The formation of this by-product can be entirely avoided if colourless nitric acid be used.

Amidopurpurin ($\text{OH}, \text{OH}, \text{NH}_2, \text{OH}$) (1:2:3:4) is obtained from the nitro-compound by reduction with ammonium sulphide and forms a brownish-red powder, producing very dull colours on mordanted fibres. In alcohol and concentrated sulphuric acid it dissolves with a reddish-yellow colour; its alcoholic solution is turned carmine on addition of caustic potash.—A. L.

The Constitution of 5-membered Ring Systems. E. Hamberger. Ber. 1891, 24, 1758–1761.

This paper consists of a theoretical discussion, which is to be followed by a series of experimental investigations of the constitution of pyrrol, pyrazol, furfuran, and allied bodies, the main issue of which is to point out that the generally accepted constitutional formulæ are quite out of keeping with the chemical behaviour of the substances in question. For instance, the nitrogen atom in pyrrol does not behave in any way like a trivalent nitrogen atom, but much more like saturated pentavalent nitrogen. Hence it is proposed to represent it by a "centric" formula thus:—

a formula much more in keeping with its properties.

Similar formulæ are proposed for other 5-membered ring systems. The author admits, however, the explanation of all the properties of this group is not entirely cleared up by his conception, and refers especially to the facts that indole is more basic than pyrrol, and that the pyrrol azo-colours have basic properties which are not in accordance therewith.

—C. A. K.

Action of Sulphur on Benzaldehyde. G. A. Parbaghia and A. Marquardt. Ber. 1891, 24, 1881—1883.

HAVING in a previous communication studied the action of sulphur on aldehydes of the fatty series, the authors now give an account of the action of sulphur on other aldehydes.

On heating 30 grms. of benzaldehyde with 10 grms. of sulphur in a sealed tube for 36 hours at 180° a reddish-coloured crystalline mass is obtained which consists of small lustrous plates and long rectangular prisms. On opening the sealed tube little or no hydrogen sulphide escapes, showing that substitution has not taken place. On treating the product with ether the crystals are dissolved, whilst nearly the whole of the sulphur and another compound remain in the residue. The ethereal solution is shaken with a solution of sodium carbonate and the alkaline extract acidified with hydrochloric acid. A copious precipitate of benzoic acid is thus obtained, and on evaporating the ethereal solution a crystalline substance remains, which on repeated crystallisation from alcohol yields beautiful white lustrous plates melting at 121°—122°. This compound proved to be stilbene by analysis and by its melting point and that of the dibromide obtained therefrom. It may therefore be assumed that the initial action of sulphur on benzaldehyde is the formation of thiobenzaldehyde, which by prolonged heating is decomposed into stilbene and sulphur. The authors in point of fact succeeded in extracting from the residue insoluble in ether by means of benzene or chloroform a compound crystallising from alcohol in lustrous white needles melting at 164°—167°. This product exhibited all the properties of the γ -thiobenzaldehyde described by Baumann and Fromm. The conversion of benzaldehyde into stilbene and benzoic acid should therefore be effected by very small quantities of sulphur, and it is shown by experiment that 1 gm. or even as little as 0.25 gm. of sulphur is sufficient for the decomposition of 25 grms. of benzaldehyde.—D. B.

Indigo-green. V. H. Soxhlet. Chem. Zeit. 1891, 15, 913—914.

On leaving Indigo-carmin in contact with an excess of commercial ammonia (20° B.) for 8 to 10 days, the solution acquires a green colour. When this is feebly acidified with dilute sulphuric acid, a solution of salt added and the whole briskly agitated and filtered, a pasty mass is left which resembles commercial Indigo-carmin in appearance, without possessing, however, its coppery lustre. It dissolves readily in warm water, and the solution dyes white yarn a colour resembling Methyl-green but retaining its green colour by artificial light. The dye is as fast to light as ordinary Indigo-carmin, but it is much more resistant to washing and to alkalis. The colour of the dye obtained by the action of ammonia on Indigo-carmin varies in shade from bluish-green to yellowish-green according to the quantity of ammonia used and the time the reagents are left in contact: the prolonged action of an excess of ammonia results in the formation of a yellowish-brown solution, from which, however, a green dye of almost the normal shade is precipitated on neutralisation with sulphuric acid. The new green is in all probability a mixture of a pure green with a yellow dyestuff. On treating a solution of Indigo-carmin with ammonia and caustic soda, a yellow colouration soon appears, but the product only yields inferior shades on wool or silk.—S. B. A. A.

p-Nitrosobenzylaniline and -toluidine. W. Boeddinghaus. Annalen, 1891, 263, 300—313.

p-NITROSOBENZYLANILINE has been briefly described by O. Fischer and Hepp (Ann. 255, 147), who first prepared it. At their request, the author has made a special study of it and some analogous compounds. It was prepared in the present instance by dissolving benzylaniline in absolute alcohol, adding amyl nitrite and alcoholic hydrochloric acid, and heating the mixture at 60° for an hour. After standing several hours, the mixture was poured into water, whereupon untransformed benzylphenylnitrosamine separated out in the solid condition, leaving the

hydrochloride of *p*-nitrosobenzylaniline in solution; from this solution the free base was precipitated by addition of ammonia. Crystallised from absolute alcohol, the base forms splendid green plates with a blue reflex; it melts at 129°, is easily soluble in benzene and hot alcohol, and sparingly so in ether; its hydrochloride crystallises in brown-yellow needles.

Benzyl-p-phenylenediamine, $\text{H}_2\text{N} \cdot \text{C}_6\text{H}_4 \cdot \text{NH} \cdot \text{CH}_2 \cdot \text{C}_6\text{H}_5$, formed by reducing the preceding compound with alcoholic ammonium sulphide, melts at 30°. It must be preserved out of contact with air, as it is quickly altered by exposure to the same.

p-Nitrosophenylbenzylnitrosamine—

is produced by the action of nitrous acid on a solution of the sulphate of *p*-nitrosobenzylaniline. The compound forms yellow needles, which, crystallised from ether, melt at 77°.

Reactions of p-nitrosobenzylaniline.—Hydroxylamine hydrochloride acts upon *p*-nitrosobenzylaniline, forming benzylaniline hydrochloride and quinonodioxime; the production of the latter proves that in the above-described nitrosobenzylaniline the nitroso group occupies the *p*-position.

Sodium hydrate decomposes *p*-nitrosobenzylaniline into *p*-nitrosophenol, *p*-amidophenol, benzaldehyde, and ammonia, thus:—

p-Nitrosobenzyl- α -toluidine was prepared from benzyl- α -toluidine by the same method as its lower homologue. After crystallisation from absolute alcohol, it melts at 115°. On reduction it yields *benzyl- α -methyl-*p*-phenylenediamine*, which forms an oil at the ordinary temperature, but at 6° is precipitated by sodium hydrate from its solution as hydrochloride in a solid powdery state. Sodium hydrate acts on *p*-nitrosobenzyl- α -toluidine similarly to what it does on *p*-nitrosobenzylaniline.

p-Nitroso-benzyl- m -toluidine, obtained from benzyl- m -toluidine (boiling point 300°) in the manner described above for *p*-nitrosobenzylaniline, melts at 121°.

p-Nitrosobenzylmethylaniline, similarly prepared from benzylmethylaniline, melts at 56°. A 70 per cent. yield of this base was obtained as against 40 per cent. in the case of the other nitroso bases prepared. Sodium hydrate decomposes it chiefly into benzylmethylaniline and *p*-nitrosophenol, but small quantities of methylaniline and benzaldehyde are also produced.—E. B.

α - β -Benzeylnaphthylenediamine. A. Koll. Annalen, 1891, 263, 313—315.

β -Benzeylnaphthylaniline is formed by condensing β -naphthylamine with benzaldehyde and reducing with sodium amalgam the benzylidene compound so produced. By the action on its alcoholic solution of amyl nitrite and hydrochloric acid at 18°, α - β -benzeylnaphthylenediamine is obtained, the nitroso compound formed immediately undergoing condensation according to the equation—

α - β -Benzeylnaphthylenediamine forms colourless, crystalline aggregates, melting at 214°. It crystallises from methyl alcohol in colourless tables or plates, containing $\frac{1}{2} \text{CH}_3\text{OH}$, and is identical with the base described by Ebcl (Ann. 208, 328) under the name of anhydrobenzylidionaphthalene.—E. B.

1:2:3 *Ortho-xyldine*. K. Menton. *Annalen*, 1891, **263**, 316—332.

For the preparation of *methyl-o-xyldine* from *o-xyldine* ($C_6H_3(NH_2)_2$ 1:2:3) Hepp's method (Ber. **10**, 327) was used, since by it the simultaneous formation of tertiary and ammonium bases is avoided. Acetyl-methyl-*o-xyldine* was readily prepared by heating at 140° for 2—3 hours well-dried acetylaldehyde, xylene, and sodium, cooling the solution, adding methyl iodide, and carefully warming on the water-bath until the reaction was completed. After filtering from separated sodium iodide, the acetyl compound was extracted from its xylene solution by repeated agitation with warm, concentrated hydrochloric acid. An attempt made to hydrolyse it by prolonged boiling of this hydrochloric acid solution failed, as also did several other methods tried with the same object, the compound being singularly stable. It was eventually hydrolysed by boiling under a reflux apparatus for 15 hours with a mixture of two parts of concentrated sulphuric acid and three of water. But even after this treatment the hydrolysis was imperfect, turbidity being produced on dilution with water. This was due to the presence of undissolved particles of the acetyl compound, which were removed by agitation with ether. The solution was then alternately treated with sodium nitrite and extracted with ether as long as a turbidity was produced on addition of the former. The nitrosamine so formed was, after evaporating off the ether, converted by the action of zinc dust and hydrochloric acid into methyl-*o-xyldine*, which was separated by distillation with steam. Methyl-*o-xyldine* is a pale yellow oil, boiling at 222—223°; it possesses the characteristic smell of secondary aromatic bases, and is easily soluble in dilute acids.

p-Nitrosomethyl-o-xyldine was prepared by acting upon an ice-cold solution of methyl-*o-xyldine* hydrochloride with nitrous acid as long as oily drops of the nitrosamine separated. These were extracted with ether; the ethereal solution, after being dried with calcium chloride, was mixed with alcoholic hydrochloric acid and allowed to stand several hours, when *p-nitrosomethyl-o-xyldine* crystallised out. The free base was separated from this salt by dissolving the latter in warm water and adding a slight excess of sodium carbonate; after washing with water, it was crystallised from 80 per cent. alcohol, and thus obtained in lustrous green needles, melting at 160°—161°.

As one of the objects of this research was the preparation of a dimethylpheninduline from nitroso-*o-xyldine*, and as, owing to difficulty in its preparation, an insufficient amount of the latter was obtained, the author prepared acetyl-methyl-*o-xyldine*, in the hope that it would be more readily hydrolysed. In this, however, he was disappointed, the acetyl-methyl compound being even more stable than its lower homologue. *Ethyl-o-xyldine* closely resembles the methyl derivative; it boils at 227—228°. *p-Nitroso ethyl-o-xyldine* forms green needles with a blue reflex, melting at 123—124°.

Experiments were made with the small quantity of *p-nitrosoethyl-o-xyldine* obtained, with a view to preparing the diethyl analogue of the induline, whose formation is mentioned by Fischer and Hepp (*Ann.* **256**, 292), but with negative results. An endeavour to prepare the latter induline, by heating phenylazo-*o-xyldine* hydrochloride with aniline, resulted in the production of a dark coloured mass from which the author extracted a *dimethylsafranine*, $C_{16}H_{13}N_3Cl$, but failed to isolate any induline compound. The formation of this safranine is scientifically of importance, as supporting Nietzki's theory. Nietzki concluded that 1:2:3-*o-xyldine* was incapable of yielding a safranine, since, when making the experiment, he only succeeded in obtaining a trace of safranine from that base, and the production of this he attributed to the presence of isomeric xyldines in the preparation he used.

Dimethyl-o-xyldine was obtained by heating trimethyl-*o-xyldine* ammonium iodide, direct methylation of *o-xyldine* with methyl alcohol and hydrochloric acid under pressure, producing chiefly the monomethyl derivative; it boils at 199—200°. Nitrous acid is without action upon it. This is probably due to the protecting influence on the molecule exerted by the alkyl group in the ortho-position to the

substituted amido group, as Riedel (Ber. **13**, 126) has shown that *o*-dimethyltoluidine is similarly unattacked by nitrous acid.—E. B.

Condensation-Products of m-Nitro-benzaldehyde with Phenol and Resorcinol. G. de Varda and M. Zenoni. *Gazz. Chim.* 1891, **21**, 174.

m-Nitro-dihydroxytriphenylmethane—

is formed by carefully heating at 130° fused *m*-nitro-benzaldehyde (1 mol.) and phenol (2 mols.) with dihydrated sulphuric acid (rather more than 1 mol.). It forms an amorphous powder, melting at 59—60°, is soluble in alcohol, slightly so in hot water, but is almost insoluble in ether, chloroform, and benzene. It dissolves readily in concentrated sulphuric acid with a red colour and in alcoholic potash with a deep purple colour, which gradually fades.

m-Nitro-tetrahydroxytriphenylmethane—

obtained by heating *m*-nitro-benzaldehyde (1 mol.) with resorcinol (2 mols.) at 150°, has a yellow colour, melts at 97—100°, is feebly soluble in boiling water, and more easily so in alcohol, ether, and acetic acid.—E. B.

Ortho-Hydroxyazo Dye-stuffs. I. D. Zibell. Schweiz. *Wochenschr. Pharm.* 1891, **29**, 186.

THE same bodies, namely, hydroxyazobenzene and phenyl-diazophenol, are obtained by the action of diazobenzene chloride on *p*-hydroxybenzoic acid as by that of the former compound on phenol, the carboxyl group in the *p*-hydroxybenzoic acid being eliminated. Diazobenzene sulphonic acid, similarly, yields hydroxyazobenzene-sulphonic acid with *p*-hydroxybenzoic acid. On the other hand, salicylic and *m*-hydroxybenzoic acids interact normally with diazobenzene chloride. The compound thus obtained from salicylic acid dyes mordanted cotton; that from *m*-hydroxybenzoic is devoid of colouring power.—E. B.

PATENTS.

The Manufacture and Production of a Sulpho-Acid suitable for Dyeing and Printing. J. Y. Johnson, London. From the "Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 14,836, September 19, 1890. (Second Edition.) 6d.

THIS is an extension of Eng. Pat. 15,259 of 1888 (this Journal, 1889, 877), and describes the preparation of a yellowish-red dyestuff for wool, by the action of dilute sulphuric acid on the so-called "higher sulpho-acid," alluded to in the previous patent. The best results are obtained by boiling the sodium salt of the "higher sulpho-acid" with about 15 times its weight of dilute sulphuric acid (containing 75 per cent. H_2SO_4) under an inverted condenser until a sample diluted with water gives a copious precipitate and the mother-liquor is yellowish-red. The melt, after cooling, is diluted with an equal weight of ice, filtered, and the precipitate dissolved in caustic soda lye, again filtered, and the filtrate precipitated with dilute sulphuric acid. It appears in commerce as the sodium salt, in the form of a brownish powder, soluble in cold water to a yellowish-red solution.—T. A. L.

The Production of Azo-Colours in Substance or on the Fibre. S. Pitt, Sutton. From L. Casella and Co., Frankfort-on-the-Maine, Germany. Eng. Pat. 15,347, September 27, 1890. 6d.

THE base for producing these colours is known as "Naphthylene-violet," obtained by combining 1 mol. of the tetrazo compound from diamidonaphthalene- β -disulphonic acid with 2 mols. of α -naphthylamine. The substance has a great affinity for animal and vegetable fibres, giving a violet shade, which, however, is not stable to acids. It can be diazotised on the fibre, and combines then with a variety of amines and phenols and their derivatives, giving a number of different shades, of which a table is given in the specification.—T. A. L.

The Manufacture of Sulpho-Acids of a Red Basic Naphthalene Colouring Matter. J. Y. Johnson, London. From the "Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 17,168, October 27, 1890. 6d.

AN extension of Eng. Pat. 14,836 of 1890 (see above). The yellow-red dyestuff there described when heated with aniline and aniline hydrochloride gives a new monosulphonic acid of phenylrosinduline. This in turn can be further sulphonated, yielding a disulphonic acid, and a higher sulphonic acid which appears to be identical with the "higher sulpho-acid" of Eng. Pat. 15,259 of 1888 (this Journal, 1889, 877). In place of aniline, its homologues may be employed, and corresponding products obtained by sulphonation of the compounds so formed.—T. A. L.

Process for the Production of Anthranilic Acid. O. Imray, London. From "Amsterdamsche Chininefabrik," Amsterdam, Holland. Eng. Pat. 18,246, November 12, 1890. 6d.

ANTHRANILIC acid is formed when phthalimide is treated with a hypochlorite or hypobromite in molecular proportions, in presence of an alkali or of an alkaline earth. The finely divided phthalimide is treated with two parts of solid caustic soda dissolved in seven parts of water, the mixture being kept cool and stirred continuously. To this the hypochlorite is added gradually in a 5.06 per cent. solution, and the whole heated to about 80° C. On cooling the solution is neutralised with hydrochloric or with sulphuric acid, and an excess of acetic acid added when a considerable portion of the anthranilic acid separates out in crystals which are dried in a hydro-extractor. The remainder of the acid is precipitated out by copper acetate, and the resulting copper salt reconverted into the acid. The hypochlorite or hypobromite of potassium, sodium, calcium, barium, strontium, or magnesium can be employed in the reaction, or chlorine or bromine may be led into an alkaline solution of the phthalimide, or, phthalimide may be first treated with bromine, subsequently an excess of alkali slowly added, and the mixture heated. The caustic soda used in the preparation as described above may be substituted by caustic potash, lime, baryta or strontia.

The reaction may be represented thus :—

Instead of taking phthalimide, phthalimic acid, which is readily prepared from it, can be employed (Asebau, Ber. 1886, 19, 1401). Anthranilic acid is of value in the manufacture of colouring matters and of chemical preparations.

—C. A. K.

Improvements in the Manufacture of Sulpho-Acids of a Red Basic Naphthalene Dyestuff. J. Y. Johnson, London. From the "Badische Anilin und Soda Fabrik," Ludwigshafen, Germany. Eng. Pat. 19,167, November 25, 1890. (Second Edition.) 6d.

A METHOD for obtaining a trisulphonic acid of phenylrosinduline, and also a higher non-crystalline acid by the action of fuming sulphuric acid on phenylrosinduline. The patent is an extension of Eng. Pat. 15,259 of 1888 (this Journal, 1889, 877), which describes the preparation of a mono- and disulphonic acid, and also of a non-crystalline acid. This latter frequently contains trisulphonic acid, which can be separated by dissolving the sodium salts in water and adding dilute sulphuric acid when the trisulphonic acid crystallises out and can be recrystallised from water containing a little brine. The non-crystalline acid remains in the mother-liquor and can be obtained as the sodium salt by neutralising the sulphuric acid with milk of lime, converting the calcium salt by soda into the sodium salt, filtering and evaporating the solution to dryness. Both the products dye animal fibres red from an acid bath. (See also Eng. Pats. 14,836 and 17,168 of 1890, abstracted above.)—T. A. L.

Improvements in the Manufacture of Colouring Matter. H. H. Lake, London. From K. Oehler, Offenbach-on-the-Maine, Germany. Eng. Pat. 11,218, July 1, 1891. 4d.

By reacting with 2 mols. of diazotised *p*-amido-acetanilide on 1 mol. of *m*-phenylene diamine in an alkaline solution a product is obtained which dissolves with difficulty in dilute hydrochloric acid. This is converted into a dyestuff by heating with concentrated hydrochloric acid on the water-bath, the colouring matter being precipitated by adding zinc chloride and salt. It forms a black powder easily soluble in water, and is specially adapted for dyeing jute and leather a dark brown.—T. A. L.

V.—TEXTILES: COTTON, WOOL, SILK, Etc.

Morrenine and Morrenol. P. Arata and C. Gelzer. Ber. 1891, 24, 1849—1853.

See under XX., page 849.

Action of Nitric Acid upon Plant Fibres. C. F. Cross and E. J. Bevan. Ber. 1891, 24, 1772—1776.

THE conclusions of J. Lifschutz in a recent paper (Ber. 1891, 24, 1186) on the action of "nitrosulphuric acid" upon plant fibres, are criticised by the authors with the view of showing that they apply only within the limited range of the experiments described. Their purpose was to ascertain the conditions for economically carrying out the well-known oxidising action of dilute nitric acid upon pine wood, *i.e.* with a minimum expenditure of the reagent to secure a maximum yield of the cellulose and oxalic acid, the chief products. Lifschutz has succeeded in obtaining a yield of 40 per cent. of the former and 30 per cent. of the latter, using a dilute acid containing 20 per cent. of its weight of HNO_3 and 32 per cent. H_2SO_4 , this mixture of acids and at this degree of concentration being found to give the best results. The conclusion is also drawn that under these conditions the action is limited to one of simple oxidation.

Reference is made by the authors in criticism of these conclusions to their previous publications in which the interaction of nitric acid and the lignocelluloses has been dealt with and shown to depend upon the specific combination of a deoxidised "residue" of the nitric acid with the

molecule of the latter. It is now pointed out that the presence of the closed ring molecules characteristic of the lignocellulose, viz. of the type—

might be expected to lead to the formation of quinonoximes by reaction with nitrous acid, the first product of deoxidation of the nitric acid by the fibre substance.

In the reaction between the jute fibre and dilute nitric acid (5 per cent.) which has been specially studied, there are formed acid products having the empirical composition $\text{C}_6\text{H}_4\text{O}_4(\text{NOH})_2\text{H}_2$ and these are decomposed as the digestion proceeds with evolution of nitrous oxide gas. The formation of the oxime and its decomposition by the nitrous acid may be expressed as follows:—

I.

II.

The consequent accumulation of oxygen determines the rupture of the carbon rings with formation of oxalic and carbonic acids as the main products, and this view satisfactorily explains the transitory character of the proximate derivatives of the lignone groups.

The formation of oximes and therefore the above views of the reaction are confirmed by the formation of hydrocyanic acid in greater or less quantity in the process of digestion.

It is probable that in the conversion of lignocelluloses into the nitrated products which are the basis of a number of the new explosives, the reaction is not simple as in the case of cotton and the pure celluloses, but complicated more or less by combination of the fibre substance with deoxidised residues of the nitric acid; and the observations contained in this paper deserve consideration in regard to this branch of manufacture.

The results may be expected to throw some light on the functions of nitric acid in the vegetable world, and further investigations in this direction are in progress.—C. F. C.

VI.—DYEING, CALICO PRINTING, PAPER STAINING, AND BLEACHING.

Fast and Fugitive Dyes. J. J. Hummel. J. Soc. Arts, 1891, 535—548.

The Action of Light on Dyed Colours.—Dyed patterns of cotton, wool, and silk, were exposed for a month (February) on the sea-coast near Bombay, a test considered equivalent to a year's exposure in England. From the results produced the following inferences have been made.

On *wool* most of the natural colouring matters suffer very considerably: Turmeric, Orchil, Catechu, and Indigo-carmin almost entirely disappear; Camwood, Brazilwood, and their allies, and Young Fustic are, on all mordants, much decolourised; Weld, Old Fustic, Quercitron bark, and Persian berries give fast colours (olives) on the chromium, copper, and iron mordants, but fugitive colours (yellows) on aluminium and tin; Logwood gives a fast greenish-black on copper, very fugitive colours on aluminium and tin, and colours holding an intermediate position on chromium and iron; Madder, Cochineal, Lac-dye, and Kermes, give fast colours on all the usual mordants; vat Indigo blue and Prussian blue are the fastest to light among colours of this group. On *silk*, the above colouring matters

show similar degrees of fastness. In some cases, however, the colours are somewhat faster on silk; for example, Catechu brown and the colours obtained with Brazilwood and its allies on the iron mordant. The fugitive character exhibited by nearly all the natural colouring matters when dyed on *cotton* is very marked. The exceptions are: the Madder colours, especially when fixed on oil-prepared cotton as in Turkey-red; the black produced by Logwood, tannin, and iron; a few mineral colours such Iron buff, Manganese brown, Chrome orange, and Prussian blue; Cochineal and its allies, which give excellent colours on wool and silk, give only fugitive colours on cotton; vat Indigo blue, again, is not so fast on this fibre as it is on wool and on silk.

A series of fast colours on wool, silk, and cotton, is afforded by the artificial "mordant-dyes." Among the yellow colouring matters of this class, Alizarin yellows R and GGW, although not true alizarin colours, are quite equal in fastness to any of the natural yellow dyes, probably faster; truer representatives of the natural dyes (giving olives on the iron mordant) exist in Gallolavin and Alizarin yellows A and C, and these are of about the same degree of fastness as the natural yellows. In the group of red dyes, Alizarin and its allies yield fast colours; the only dyes of this group which are somewhat behind the rest in point of fastness are Purpurin and Alizarin-maroon. Fast blues and greens are furnished by Alizarin-blue, Alizarin-cyanin, Alizarin-indigo, Alizarin-green, and Cerulein. Further, an excellent group of colouring matters giving fast browns and greens with copper and iron mordants respectively, is formed by Naphthol green, Resorcinol green, Gambin, and Dioxin. The only fugitive artificial dyes of this mordant-dyeing class are some of the yellows, Gallamine blue, and Gallocyanin.

The substantive or "direct" class of artificial dyes is composed in the main of fugitive dyes. Magdala red on silk appears tolerably fast, and on cotton Indophenin, Paraphenylene blue, Cinereine, and Meldola's blue, are a little faster than the rest. Biemrich scarlet, Brilliant crocein, and other azo scarlets, crimson, and clarets show a considerable degree of fastness on wool and silk, as also do Crocein orange, Aurantia, Orange crystal, Tartrazin, Milling yellow, and Palatine orange on wool, and Acid yellow D, Brilliant yellow, Azo-acid yellow, Metanil yellow, Curcumin S, and others on silk. It is interesting to note the decidedly fugitive character on silk of Tartrazin, Aurantia, Orange crystal, &c. as compared with their great fastness on wool. All the "Acid" greens and blues are fugitive both on wool and on silk; Patent blue appears slightly better than the rest. Of the "Acid" blacks and violets, &c., a few colours are of medium fastness both on wool and on silk, namely, Naphthol black, Naphthylamine black, Resorcinol brown, Fast brown, and one or two others.

In the benzidine class of colours, amid a number of very fugitive dyes, there are a few of satisfactory fastness: Diamine fast red, for example, is quite remarkable for its fastness both on wool and on silk, and may certainly rank with Alizarin; but on cotton it is quite as fugitive as the rest. Of medium fastness on wool are Brilliant congo G and R, and Congo G R; and on silk, Diamine scarlet R, Deltapurpurin 5 B, and Brilliant congo R. On cotton the yellows of this class appear to be the fastest, but are only of medium fastness; Mikado orange R, 4 R, G, Hessian yellow, Curcumin S, Chrysophenin. On wool, Benzo orange, Congo orange R, Chrysophenin G, Chrysamine R, and Brilliant yellow, are moderately fast. On silk some of the fastest yellows and oranges obtainable from any source on this fibre are yielded by Congo orange R, Chrysophenin G, Diamine yellow N, Brilliant yellow, Curcumin W, Benzo orange, Hessian yellow, Chrysamine G and R, Cresotin yellow R and G, Cotton yellow G, and Carbazole yellow. Few colours among the "Congo" violets, blues, and purples, are found worthy of particular notice for fastness; Diamine violet N appears, perhaps, of medium fastness on wool and silk, whilst Sulphonazurin, Benzo black-blue, and Direct grey may claim the same distinction on silk.

The intensity or depth of a colour has considerable influence on its fastness. Dark full shades invariably appear faster than pale ones produced from the same

colouring matter, simply because of the greater body of pigment present. A pale shade of even a fast colour like indigo will fade with comparative rapidity. The fugitive character of many of the coal-tar colours is, in the author's opinion, rendered more marked, because, owing to their intense colouring power there is often such an infinitesimal amount of colouring matter on the dyed fibre.

The author's opinion, based upon general observation, is that a fugitive colour is not rendered any faster to light by being applied along with a fast colour. When light acts upon a compound colour, the unstable colour fades, while the stable colour remains behind. A woaded colour, for example, is only fast in respect of the vat indigo it contains.

The Action of Milling on Colours.—Fast to milling, especially with respect to bleeding, are all those phenolic colouring matters of which alizarin may be taken as the type. These do not bleed because in the dyed fibres they form, in combination with the mordants, an insoluble precipitate which is largely enclosed within the substances of the fibres. That portion of the precipitate which lies on the surface is undoubtedly removed mechanically during the milling process; but even then, since the colouring matter is combined with the mordant and is not in the free state, it cannot combine with the mordants of neighbouring dyed fibres, nor can it be attracted by and stain unmordanted white fibres. Phenolic colouring matters, however, are liable to bleed if they be improperly applied.

Colouring matters of the triphenylmethane group, azo scarlets, nitro dyes, and some other basic and acid colouring matters, nearly all bleed during milling. The dyed colours themselves, perhaps, are not materially impoverished, so that a plain dyed fabric might be milled with impunity, provided the soap used be not too alkaline; nevertheless such colouring matters are practically useless for tweeds and the like, where variously-coloured fibres are interwoven. It is interesting to note, however, that many of the "direct" dyes are perfectly fast to milling. Even in the triphenylmethane group there are a few specially remarkable exceptions to the rule; for example, Victoria blue and Night blue. Members of the Eosin group are also generally characterised by their fastness to milling. Most noteworthy for fastness to milling is the whole group of "Congo" dyes. This fastness, however, only extends to wool; any white cotton fibres in the fabric milled would certainly be stained.

Many "direct" dyes, more particularly those of the "acid" class, have the defect of being greatly impoverished in colour during milling, even to the point of almost total extinction. Examples of this class are Acid magenta, Azo scarlets and oranges, Indigo carmine, &c. In the cases referred to the colour is partly or entirely restored by passing the milled piece through dilute sulphuric or acetic acid. The reason of this decolorising action is very evident. The alkali of the soap neutralises the "colour acid" on the dyed fibre, and produces a pale-coloured, or even colourless, alkali salt of the colour acid. The restoration of the colour during the subsequent passage through acid is due to the decomposition of the colourless alkaline salt, with the liberation of the original highly-coloured colour acid.

Some colours, both such as are dyed directly, or even with the aid of mordants, have the defect of being entirely altered in hue during milling; thus, Cochineal scarlet becomes crimson, Orchil purple becomes violet, Turmeric yellow becomes brown, and so on. Here, again, the alkali of the soap either dissolves or decomposes the lake, or it combines with the colouring matter to form a differently coloured compound.

The Action of Scouring on Colours.—When wool has been dyed in its loose, unspun condition, it is dried and impregnated with oil to facilitate the carding and spinning processes. The yarn or cloth made from such dyed fibre has therefore to be submitted to the operation of scouring, in order to remove the oil of the spinner. It consists in washing the material in a warm solution (50—60° C.) of soap or carbonate of soda, or a mixture of the two, until the oil is entirely removed. The stronger alkali, and the higher temperature employed, cause the operation of scouring to be even still more searching on dyed colours than that of milling. Those colours which are altered in hue, de-

coloured, or impoverished in colour by milling are much more altered by scouring. Some—for example, Prussian blue—are entirely decomposed.

Very susceptible to the action of scouring are the sulphonic acid colours, and, indeed, for the same reasons as are explained above. Fast to scouring, as a rule, are the "mordant dyes," the Eosins, Congo colours, and some others.

All coloured goods should be washed or scoured at a low temperature, and with a soap which is as neutral as possible.

Action of Stoving on Dyed Colours.—In some instances dyed colours must be fast to what is known as the operation of "stoving." Such is the case, for example, with those coloured yarns which form the striped headings of blankets, with many kinds of woollen hosiery, &c. In goods of this kind, white and dyed fibres are interwoven or even spun together, and the materials are submitted to a final bleaching with sulphurous acid, so that the white fibres, which have become soiled during the spinning and weaving operations, shall ultimately appear in all their original purity.

Many "acid" and "mordant" dyes withstand this stoving operation, but others are more or less altered in colour, or are entirely decolourised, either because the colouring matter is reduced or the colour-lake is decomposed, by reason of the acid vapours.

Action of Acids on Dyed Colours.—Fastness to acids is required from the colours on cotton yarn intended to be woven with white woollen or worsted weft, which is subsequently dyed with acid colours. Further, the colour of all materials intended to be worn next the skin should be fast to acids, since perspiration contains such organic acids as acetic acid, butyric acid, &c., and although the acidity of perspiration is slight—indeed it is sometimes alkaline—still it can exercise considerable influence on dyed colours, in consequence of the additional action of friction and heat, and by its concentration upon the fibre.

Fast to acids are many of the "mordant" dyes, and also those colours which are dyed in an acid bath, provided the acidity be not too great. Basic colours, and most of the "Congo" colours, are very sensitive to acids.

The Rubbing-off of Dyed Colours.—No colour can be considered fast if it have this defect, and yet, strange as it may appear, Indigo, one of our fastest dyes in other respects, is particularly unfortunate in this one.

Of defective coal-tar colours in this respect, Malachite green and Victoria blue may be mentioned; indeed, all the basic dyes show the defect more or less, especially if they be heavily dyed. Acid colours and Congo colours, as a rule, are free from the defect. On the other hand, even mordant dyes are liable to rub off if they be improperly applied.

Not unfrequently, in the case of wool, the fault is due to insufficient scouring, the employment of hard water, or from some similar cause, the fibre becoming permeated or coated with lime-soap or with grease in some form or other, which either fixes the dye on its surface or prevents the effectual penetration of the mordant or dye solution.—E. B.

Permanent and Fugitive Colours to Light on Wool T. Frisner. J. Soc. Dyers and Colourists, 1891, 82—84

The author has exposed to light for a period of 40 days samples of a number of dyed colours, with the following results:—Of the natural colouring matters, Camwood, the fastest of the red woods, and Fustie, the fastest of the yellow woods, both fade a little; Logwood, in pale shades, is considerably decolourised, the destruction of colour not being so apparent in dark shades; Logwood blacks "finished" with chrome, turn greener than unfinished blacks; vat-dyed Indigo gives the fastest of all blue colours. Amongst the artificial colouring matters tested, Alizarin blue and Anthracene brown, in pale shades, are only moderately fast; Gallocyanin is not quite so fast as Alizarin blue; Naphthol black, Diamond black, Anthracite black, and other wool-substantive azo-blacks are much faster to light than Logwood-black.—E. B.

Metallic Sulphites in Calico Printing. J. Mullerus.
Chem. Zeit. 1891, 15, 911.

Chromium bisulphite is largely used for mordanting dress-goods on which the fashionable grey, blue, rose, olive, and other light self colours are to be produced. Better results are obtained by using mixtures of the sulphites of two or more metals, the dyeing bath being in this case more easily exhausted, the colour more equally distributed, and a larger variety of shades possible. The following are suitable mixtures:—

I.

500 cc. of chromium bisulphite 16° B.
500 cc. of aluminium bisulphite 16° B.
2 litres of gum tragacanth 100:1,000.
13 litres of water.

II.

500 cc. of chromium bisulphite 16° B.
500 cc. of iron bisulphite 16° B.
2 litres of gum tragacanth 100:1,000.
13 litres of water.

The goods are mordanted, dried in the hot blue, printed with a discharge consisting of—

700 grms. of citric acid.
600 cc. of water.
600 cc. of caustic soda 26° B.
800 grms. of burnt starch.
1,200 cc. of gum water (Senegal).

Either sodium silicate or arseniate or cows' dung and chalk may be used for dunging. The chromium aluminium mordant gives a clear fawn (chamois) on dyeing with a mixture of 600 grms. of Anthracene brown (20 per cent.), 600 grms. of quercitron extract (30° B.), and 360 grms. of Persian berries extract (30° B.); a reddish bronze with 1,500 grms. yellow alizarin (20 per cent.), 1,500 grms. of Anthracene brown (20 per cent.), 4,000 grms. extract of Quercitron (30° B.), and 2,000 grms. extract of Persian berries (30° B.), 1 kilo. being used per 100 metres of cloth; and a bluish rose colour with 20 per cent. blue alizarin, using 500 grms. per 100 metres.

With the chromium iron mordants a sea-green is obtained by dyeing with Resorcinol green (300 grms. per 100 metres); a blue with Galloxyanin, and all varieties of grey and olive shades by mixing Resorcinol green with Galloxyanin. Some of the shades may be improved by the addition of quercitron. These dyes are fast to light and soap, and are remarkable for their agreeable tints.—S. B. A. A.

Fast Black—a Preparation of Logwood. H. Gutknecht.
Chem. Zeit. 1891, 15, 919.

For some time past, a product obtained by the oxidation of logwood with potassium bichromate, has been largely employed in the black-dyeing of cotton goods. The following is a recipe for its preparation:—To a mixture of 100 kilos. of logwood extract at 25° B. and 25 kilos. of crude glycerin, there is gradually added, with constant stirring, an oxidising solution composed of 8 kilos. of potassium bichromate, 15 kilos. of chrome alum, 50 litres of water, and 12.6 kilos. of hydrochloric acid at 20° B. The logwood-glycerin mixture, whilst undergoing oxidation, is heated to 100°, and this temperature is maintained for 1—2 hour after completing the addition of the oxidising solution. After cooling and allowing to stand for 12 hours, the product, which should be free from any sediment, is ready for use.

For use in cotton dyeing, 3—6 per cent. (of the weight of the cotton) of the above preparation is dissolved in water at 20°, the material to be dyed introduced, and the temperature of the bath raised to 40° in the course of 25—30 minutes.

To render it suitable for printing, the preparation is treated with 12 per cent. of its weight of sodium bisulphite at 40° B., and allowed to stand for about eight days. It yields a good black when printed on calico and steamed.

A cheap black ink may be prepared by diluting the oxidised logwood preparation (1 part) with water (10—15 parts), thickening with glucose, and neutralising with sodium carbonate (about $\frac{1}{2}$ per cent.).

Glucose may be used instead of glycerin in the above recipe.—E. B.

Preparation of Catechol. H. Gutknecht. Chem. Zeit.
1891, 15, 959.

The Tannin Matters of Algarobilla and Myrabolams.
G. Zoffel. Arch. Pharm. 1891, 229, 123.

UNDER the general name of Algarobilla (Algarobito, Algarobo, &c.), the pods of several species of *Casalpinia*, notably those of *Casalpinia brevifolia* (known also as *Balsamocarpum brevifolium*), are employed in Chili for tanning and dyeing. Attempts are now being made to find a suitable use for them in Europe.

Algarobilla contains two tannin matters, namely, a glucoside, gallotannin, to the extent of 8—10 per cent., and a tannic acid of the formula $C_{14}H_{16}O_{10}$, in comparatively larger amount. The latter substance is easily resolved into ellagic acid, and is consequently named by the author ellagotannic acid. It is identical with the acid isolated by Löwe from divi divi and myrabolams. It contains five hydroxyl groups, replaceable by acetyl groups, and has the constitution $C_6H_2(OH)_5CO.O.O.C_6H_2(OH)_5COOH$.

According to Schiff, the formula of air-dried ellagic acid is $C_{11}H_6O_5.H_2O$, $C_{11}H_6O_5$ being obtained on drying at 100°, and $C_{11}H_6O_5$ at 180—200°. The author, on the other hand, finds that air-dried ellagic acid has the composition $C_{11}H_6O_5.2H_2O$, and that it loses 2 H_2O at 100°.

Myrabolams contain the same tannin principles as algarobilla, and in similar ratio.

A small quantity of gallic acid is present in both myrabolams and algarobilla, and the former contain, in addition, a little oxalic acid.—E. B.

Bleaching of Cotton by Means of Oxygenated Water.

M. Prud'homme. Compt. Rend. 1891, 112, 1374—1376.

THE addition of calcined magnesia to oxygenated water when employed for bleaching cotton has been recognised as very advantageous. Its action is due to the formation of a peroxide of the formula $3 Mg(OH)_2 + MgO(OH)_2$, which loses all its active oxygen at 300° C., but which is more stable than peroxide of hydrogen at 100° C. This peroxide has an alkaline reaction, and is formed when metallic magnesium is dissolved in oxygenated water. The oxides of zinc and cadmium behave similarly, the peroxide of the former having the composition $2 ZnO + ZnO(OH)_2$.

In the bleaching of cotton oxygenated water does not act simply as a decolourising agent, but attacks both the fatty bodies present and the cellulose, directly. The saponification of oils and fats is effected in part by the magnesia, but the oxygenated water has also a direct action. On boiling a considerable amount of carbon dioxide is evolved, due to the oxidation of glycerol, whilst the neutral fatty bodies are also acted upon by acidulated oxygenated water with the formation of fatty acids and the evolution of carbon dioxide. The fatty acids themselves are still further oxidised both by the magnesia and by the oxygenated water, and the oleic acid formed is also partially converted into palmitic acid. The fatty bodies remain in the fibre as oleates and palmitates, &c. of magnesia, and are eliminated by treatment with dilute acid and alkali successively. Cellulose is transformed into oxycellulose by oxygenated water, an action which is much aided by the presence of metallic oxides, and also by mercerising the cellulose beforehand, that is by adding caustic soda to the bath used. A piece of cloth mordanted with iron, chromium, and alumina was considerably attacked

by the oxygenated water in the parts covered by the mordants in 1–2 hours; it is therefore advisable to place the cloth, previously to bleaching it, in a bath of dilute acid so as to remove any metallic salts or oxides that may be present. An ammoniacal copper solution acts upon cellulose very similarly to oxygenated water, and when employed in dilute solution, so as not to disintegrate the fibre, is found to act as a bleaching agent and to give rise to the formation of oxycellulose. Schweitzer's reagent therefore does really attack cellulose, a fact which is contrary to the generally accepted view of its action.

—C. A. K.

PATENTS.

Process and Appliances for Washing, Bleaching, and Dyeing Fibrous Materials. O. Hoffmann, Neugersdorf, Germany. Eng. Pat. 14,839, September 19, 1890. 11d.

In the washing, dyeing, and bleaching of fibrous materials the patentee ensures perfect penetration of the liquors used by enclosing the material in a vessel, which is subjected to "movements and shocks or concussion in the manner of the head of a hammer." To protect the vessel from injury there are provided "layers of caoutchouc, wood, springs, or equivalent substance or device." A special form of centrifugal machine by which the above object is attained, is also claimed. The mechanical details are explained in the original specification with the aid of drawings.—E. B.

Process for Dyeing Textile Materials of all Kinds in the Hyposulphite Vat. C. D. Abel, London. From M. M. Rotten, Berlin, Germany. Eng. Pat. 17,326, October 29, 1890. 6d.

Three claims are made: First, the employment of a bath of hydrogen dioxide for oxidising the indigo-white absorbed by textile fibres in the process of dyeing of the same with indigo, the materials being passed directly from the indigo-vat into the hydrogen dioxide bath; second, the addition of ammonia to the hydrogen dioxide bath "for the purpose of maintaining the indigo-white in a uniform solution suitable for oxidation, for the production of light tints;" and, third, the addition, at intervals, of acid sodium hyposulphite (crude) to the dye-vat, when in use, to remove excess of alkali therefrom.—E. B.

Improvements in the Method of and Apparatus for the Production of Plates for Colour Printing. J. Michaud, Paris, France. Eng. Pat. 17,382, October 30, 1890. 8d.

By means of this invention, which is described in the original specification with the aid of drawings, the position of each one of a number of printing plates, inserted in curved letter-press printing plates for the purpose of printing illustrations in several colours, is exactly indicated on the cylinder of the printing machine, thus enabling a perfect register to be at once obtained.—E. B.

Improvements in Machines for Dyeing Skeins or Hanks. P. J. Grandsire fils, Paris, France. Eng. Pat. 19,158, November 25, 1890. 8d.

The machine appears to be substantially the same as that patented by La Société Grandsire et Fils (Eng. Pat. 15,881 of 1889; this Journal, 1890, 174), an arrangement being, however, now added by means of which, when the machine is working, the hanks are alternately lifted out of, and lowered into the dye-vat, in addition to their being moved horizontally round the vat and vertically on the reels, as described in the specification referred to.—E. B.

Improvements in the Production of Black Azo-Colours upon Fibres. B. Wilcox, London. From the "Farbenfabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 9636, June 6, 1891. 6d.

THE *p*-amidonaphtholsulphonic acid, whose employment for the production on the fibre of black azo-colours has been claimed by the present patentee (Eng. Pat. 8530 of 1890; this Journal, 1891, 697), can be advantageously replaced for the same purpose by the amidonaphtholdisulphonic acid (Eng. Pat. 13,443 of 1890) obtained from naphthalenetrisulphonic acid (Ger. Pat. 38,281). Satisfactory results are obtained with the dyes formed (1) by combination of two mols. of this acid with one mol. of the tetrazo derivatives of benzidine, *o*-tolidine, *p*-diamidophenyl-*o*-tolyl, *p*-diamidoalkoxydiphenyl, *p*-diamidoalkoxyphenyltolyl, diamido-*o*-diphenol ether, diamidodiphenoxylacetic acid, *p*-diamidostilbene, diamidofluorene, or α , α '-diamidonaphthalene; or (2) by combination with the preceding tetrazo derivatives of one mol. of the above-mentioned acid and one mol. of another "dyestuff component;" or (3) by combination with these tetrazo derivatives of one or two mols. of α -naphthylamine or α -amidonaphthol ether, diazotisation of the resultant dyestuffs, and further combination with two mols. of amidonaphtholdisulphonic acid, or with one mol. of the same and one of another "dyestuff component." The following is an example of the application of this invention: About 10 kilos. of cotton are dyed (blue) with 0.6 kilo. of the colouring matter obtained from tetrazodiphenyl and amidonaphtholdisulphonic acid (2 mols.), then rinsed and passed into a cold solution of 0.2 kilo. of sodium nitrite in 200 litres of water, acidulated with 0.6 kilo. of hydrochloric acid at 20° B. After being rinsed again, the cotton is introduced into a solution of 0.5 kilo. of sodium 8-naphtholate. A black is thus obtained, which is very fast to washing. When, instead of the dye obtained from tetrazodiphenyl and amidonaphtholdisulphonic acid, the above-mentioned analogous dyes are employed, or when, in place of β -naphthol, other "dyestuff components" are used, violet-black, brown-black, blue-black, and green-black shades are obtained.—E. B.

VII.—ACIDS, ALKALIS, AND SALTS.

Artificial Periclase; a By-Product of the Magnesium Chloride Industry. R. Otto and J. H. Kloos. Ber. 1891, 24, 1480–1482.

PERICLASE is a crystalline variety of magnesia, in which the magnesia is partially replaced by ferrons oxide. It occurs naturally in the limestone found at Monte Somma, Vesuvius, and forms greenish, greasy crystals, which in hardness are about equal to felspar. The authors have discovered crystals resembling periclase in a furnace employed for the manufacture of chlorine and hydrochloric acid from magnesium oxychloride, which was being repaired. Large accumulations of heavy magnesia were removed from parts of the furnace usually inaccessible, and the artificial periclase was found on the interior surface of a number of cavities existing in this magnesia. The crystals were octahedral in shape, and varied in size, the largest having edges 4 mm. in length. They exhibited a brilliant diamond-like lustre, and showed signs of scalariform growth. The smaller crystals were colourless, but the larger ones had a yellowish tint. Their specific gravity was found to be 3.555–3.571, and hardness between that of felspar and quartz. The crystals gave the following results on analysis:

	I.	II.
MgO	98.21	97.94
Fe ₂ O ₃	1.57	1.70

—H. T. P.

Occurrence of Ammonium Chloride in Stassfurt Potassium Salts. E. Neimke. Chem. Zeit. 1891, **15**, 915.

THE author has found as much as 0.8 per cent. of ammonium chloride in commercial carnallite. The crude potash salts and the salts and liquors obtained in the treatment of crude carnallite contain appreciable quantities of ammonia. Kieserite, however, and the calcined potassium chloride do not contain a trace.

These ammoniacal compounds are probably derived from nitrogenous organic matter present during the deposition of the potash beds, and converted into ammonium chloride by the action of the magnesium chloride.—S. B. A. A.

The Action exercised by Alkaline Bases on the Solubility of Alkaline Salts. M. Engel. Compt. Rend. 1891, **112**, 1130—1132.

IN continuation of a series of experiments on the solubility of salts of the alkalis in presence of acids, bases, or other salts, the author has determined the solubility of sodium chloride in presence of sodium hydroxide, and the following table contains the results, the figures of the first three columns representing molecules in a saturated solution at 0°. The specific gravity is at the temperature of the laboratory.

NaCl.	Na ₂ O.	Sum Total.	Sp. Gr.
54.7	0	54.7	1.207
49.375	4.8	54.175	1.221
47.212	6.725	53.937	1.225
42.375	10.466	52.841	1.236
39.55	14.78	54.33	1.249
34.35	39.5	55.45	1.265
19.3	37.875	57.175	1.314
9.498	53.25	62.748	1.362

Sodium hydroxide precipitates sodium nitrate in a similar manner from its saturated solution, and potash acts also similarly on saturated solutions of the chloride, bromide, iodide, and nitrate of potassium.

Ammonia, however, acts differently, and does not precipitate ammonium chloride from its solution. This the author refers to the formation of a double salt of ammonia and ammonium chloride.—J. W. L.

On the Persulphates. Berthelot. Compt. Rend. 1891, **112**, 1481—1483.

OWING to the recent publication of researches by Traube on the same subject, the author gives an instalment of his results. A solution containing a mixture of sulphuric and persulphuric acids, as obtained by electrolysis, is carefully neutralised by baryta or potash, and the solution will then contain a certain quantity of a neutral persulphate, which decomposes rapidly, especially on heating. The solution then again becomes acid under evolution of oxygen gas, the dissolved persulphate breaking up according to the equation $S_2O_8K_2 + H_2O = SO_4K + SO_4H_2 + O$.

If baryta is used for neutralisation, the solution containing the persulphate, S_2O_8Ba , can be filtered from the precipitated barium sulphate, and its composition can be more satisfactorily determined. It becomes decomposed on boiling in the same way as the potash salt. The solution often contains hydrogen peroxide, so that the active oxygen, as determined by titration with ferrous sulphate or potassium iodide, will often exceed that required by the formula $S_2O_8H_2$.—G. H. B.

PATENTS.

Process for Utilising the Silicic Fluoride obtained by the Treatment of Certain Phosphates with Sulphuric Acid. E. Richters, Saarbr., Germany. Eng. Pat. 15,394, September 29, 1890. 6d.

IT is proposed to condense the escaping gases resulting from the treatment of certain phosphates with sulphuric acid in wooden or stoneware receivers, with or without the admission of steam or water (the object of the water being the decomposition of any silicic fluoride), whereby fluosilicic acid and silicic acid are formed. On treatment with water fluosilicic acid dissolves, and the solution (preferably of a strength of 15—20 per cent. by volume) is treated with aluminium hydrate and caustic alkalis; the product is a double fluoride of the alkali and aluminium (artificial cryolite) mixed with silicic acid. Pure cryolite may be obtained when using a weak solution of an alkaline aluminate and alkaline carbonate, in which silicic acid is soluble.—H. A.

Improvements in the Manufacture of Chlorate of Soda. D. Gamble, St. Helens. From A. R. Peechney, Salindres, France. Eng. Pat. 16,460, October 16, 1890. 4d.

WELDON'S process (Eng. Pat. 424 of 1881) for manufacturing sodium chlorate (see also this Journal, 1882, 40—41) consists in treating milk of lime with chlorine, and decomposing the calcium chlorate so formed with sodium sulphate. It is proposed to unite the two operations in one by treating with chlorine a mixture of equivalent quantities of milk of lime and, preferably solid, sodium sulphate. The liquor so obtained has the advantage of being more concentrated than that obtained in the usual way.—H. A.

Method of Utilising the "Weldon" Plant for the Manufacture of Precipitated Phosphates. P. de Wilde, Brussels. Eng. Pat. 11,965, July 14, 1891. 4d.

THE stills and neutralising wells may be used for dissolving phosphatic rock in hydrochloric acid. The acid solution is then pumped into the top settlers, the clear liquor run into the oxidiser, and a current of air blown in, to effect an intimate mixture with the milk of lime, which is simultaneously added. The mass is then run into the mud-settlers and, after undergoing a series of washing operations, is filter-pressed and dried.

The settlers and oxidisers are lined with lead. "The pump and its pipes should also be constructed of acid-resisting material."—H. A.

X.—METALLURGY.

On Nickel Carbon Oxide and its Application in Arts and Manufactures. Ludwig Mond, F.R.S. British Association, Annual Meeting, Section II., 1891.

THE fact that under ordinary circumstances nickel alone is acted on when a mixture of this metal with any other metallic or mineral substances is treated by carbonic oxide gas, led the author to institute experiments to ascertain whether it would not be possible by means of carbonic oxide to extract nickel direct from its ores, and such metallurgical products as nickel speiss and nickel matte. As the nickel is volatilised at the ordinary temperature in the form of a vapour disseminated through other gases from which it can be deposited without first condensing the nickel compound, by simply heating these gases to the moderate temperature of 200° C., as it is thus obtained in the form of

bright coherent masses of great purity, as the carbonic oxide used is completely liberated and can be employed over and over again, and as small quantities of the poisonous nickel compound which may escape decomposition would thus never leave the closed apparatus in which the process would be carried out, it seemed probable that such a process might be capable of industrial application, and might prove more economical than the very complicated operations metallurgists have now to resort to to produce tolerably pure nickel.

Experiments carried out in conjunction with Langer, with a great variety of nickel ores from all parts of the world, containing from 4 to 40 per cent. of nickel, as well as a number of samples of nickel speiss and nickel matte, have proved that as long as the nickel is combined with arsenic or sulphur the process is entirely successful on a laboratory scale. In the majority of cases the author was able to extract the nickel almost completely in three or four days. Such ores or matte or speiss have in the first instance to be calcined, so as to convert the nickel completely into oxide. The mass is then reduced in a current of hydrogenous gases, in practice water-gas at a temperature of 450° C. It is cooled down to ordinary temperature and treated with carbonic oxide in a suitable apparatus. For this purpose any good apparatus for treating solids by gases, of which a great number are in common use, will answer. Methodical apparatus moving the reduced ore in opposite directions to the current of carbonic oxide, at the same time exposing fresh surfaces, facilitate the operation. After a certain time the action of the carbonic oxide upon the nickel becomes sluggish. The mass is then heated to about 350° C. in a current of carbonic oxide, which regenerates the activity of the nickel. This may be done in the same apparatus, but it is preferable to use a separate apparatus connected with the first, and from which it is returned to the first by mechanical means, so that each apparatus can be kept at the same temperature. The carbonic oxide gas can be employed dilute, as it is obtained from gas producers; but since it is continuously recovered, a purer gas such as can be cheaply prepared by passing carbonic acid through incandescent coke is more advantageous, as it extracts the nickel more quickly and requires smaller apparatus. The gas charged with the nickel compound leaving the apparatus is passed through tubes or chambers heated to about 200° C., in which the nickel is deposited. The gas leaving these tubes is returned to the first apparatus, and circulates continuously. From time to time the nickel is removed from the tubes in which it has been deposited. To facilitate this operation thin nickel sheets bent to fit the tubes, are inserted, on which the nickel deposits, and which are easily taken out. The metal so obtained is almost chemically pure; only very rarely in the case of certain ores it is slightly contaminated with iron. Its density is equal to that of ordinary sheet nickel. Its mechanical properties still await investigation. As the nickel is deposited in perfectly coherent films upon heated surfaces exposed to the gas containing the nickel carbon oxide, it was found possible to produce direct from such gas articles of solid nickel or goods plated with nickel resembling in every way those obtained by galvanic deposition of metals, and reproducing with the same exactitude and fineness any design upon such articles. This result can also be obtained by immersing heated articles in a solution of nickel carbon oxide in such solvents as benzole, petroleum, tar oils, &c., or by applying such solution to the heated articles with a brush or otherwise. These processes open up a wide perspective of useful application, considering the many valuable properties of nickel, especially its power of resisting atmospheric and other chemical influences. (See also this Journal, 1891, 644, and 1890, 808—809. See following abstract.)

Compounds of the Metals with Carbon Monoxide.
V. Wartha. Chem. Zeit. 1891, 15, 915.

THE author has repeated some of the work of Mond, Langer, and Quineke (this Journal, 1890, 808; 1891, 644; also previous abstract) on the compound of nickel with carbon monoxide, using however some impure ferrous nickel

oxide as the source of the metal. Under these circumstances the condensed nickel compound has always a yellow tinge, and contains iron, as do also the nickel films obtained by heating the conducting tube. The liquid after standing for a few hours, even in a sealed tube, deposits a brown compound containing iron, which often explodes with great violence when the liquid is poured off, the sides of the tube being simultaneously covered with a film of nickel. An apple-green precipitate containing nickel is occasionally deposited, together with the brown iron compound, and adheres strongly to the sides of the tube. The vapour of the liquid compound exploded upon one occasion very violently, either owing to the presence of a particle of the iron compound or to its own explosive properties.

—S. B. A. A.

Antimony Mining in Portugal. J. H. Vogel. Zeits. f. angew. Chem. 1891, 11, 326—328.

Deposits of antimony are met with in all parts of Portugal. The chief of these occur in the northern part of the country. Besides the mines of Braganza, those that lie in the district around Oporto are the most notable. Northwards from the Douro, within an area of 10 kilometres wide and 60 kilometres long, through which flow the Sousa and the Ferreira, tributaries of the Douro, lie immense deposits of antimony and lead ores, together with tin and wolfram ores. The district is also rich in brown coal. The ores of antimony in these deposits are nearly all rich in gold and silver. The mines are mostly worked with Portuguese and English capital, under German engineers. The gold sometimes occurs in particles the size of linseed in the ore, as in the mines of Ribeiro da Serra and Pontinha. The ore, which is almost all sulphide of antimony, is washed and separated into four qualities. The first three products are shipped to England, where the ores are smelted, scarcely any of the minerals of Portugal being smelted in Portugal. Samples of these three qualities analysed by the author gave—1st product, 65 per cent. antimony sulphide; 2nd product, 54.5 per cent.; and third product, 49 per cent. The fourth quality contains between 30 and 45 per cent. of sulphide, and will not bear the cost of exportation. English buyers declare that they cannot profitably extract the gold and silver as well as the antimony, and the ore is valued only upon its yield of antimony. The author is not in a position to give the maximum contents of gold and silver found in Portuguese antimony ores, but the three samples above mentioned, were said to be especially poor in gold and silver. They yielded on assaying as follows per ton (metrical) of ore:—2nd product, 15 grms. of silver and 5 grms. of gold; 3rd product, 30 grms. of silver and 16 grms. of gold. These amounts of silver and gold may be considered as minimum quantities, for the ores of this class. An attempt was made by an English company at Lixa, near Oporto, in 1889, to extract the antimony electrolytically, and at the same time recover the gold and silver, but the work was abandoned as being too costly. A practical method of recovering these three metals has yet to be discovered. Another question to be solved is the utilisation of the fourth product, containing between 30 and 45 per cent. of antimony sulphide, and the solution can only be arrived at by smelting the material on the spot. Unsuccessful attempts have been made in the neighbourhood of Coimbra to smelt the ores. The author states that he has succeeded in treating these poorer products so as to obtain nearly their whole contents of antimony, and also that he has devised another method by which the antimony is recovered as oxide, and by which the sulphur is made available.

The deposits of antimony ore next in importance occur near Coimbra, and in this district the rarer oxide of antimony is found in ores containing as much as 70 per cent.

In the south and south-east of Portugal, in the province of Alentejo, considerable deposits of antimony are found which some 25 years ago were worked very profitably.

—H. S. P.

PATENTS.

Process for Obtaining a New Metallic Alloy. T. Held, Menden, Germany. Eng. Pat. 13,413, August 26, 1890. 4d.

AN alloy resembling gold in appearance is produced by adding 6 per cent. by weight of antimony to molten copper. When the metals have become alloyed with each other, 10 grms. of "ashes or dust from charcoal" and 25 grms. of caespar are added to the melting-pot for every kilo. of alloy. The alloy produced as described can be rolled, hammered, and soldered; it has the appearance of gold when polished, and is considerably tougher and harder. According to the patentee it may be exposed to the action of acid or ammoniacal fumes for a long time without losing its brilliancy.—S. B. A. A.

Improvements in the Treatment and Reduction of Metallic Ores or Compounds and the Recovery of Metals and Products therefrom. A. J. Campion, Margate, and J. E. Tenison-Woods, London. Eng. Pat. 15,806, October 6, 1890. 6d.

ACCORDING to this invention, metallic oxides, chlorides, &c., are reduced by hydrogen gas, and sulphides by successive treatment with steam and hydrocarbon gas. The necessary hydrogen is obtained by passing superheated steam through molten iron in a closed vessel, the iron when fully oxidised being subsequently reduced to the metallic state for use over again by passing a current of hydrocarbon gas over it. For the reduction of the oxides, &c., of the metals crucibles are preferably used shaped like ordinary glass-pots, and made of fireclay or plumbago in the case of antimony, barium, strontium, bismuth, cadmium, cobalt, copper, nickel, and metals of the platinum group, of powdered emery and gelatinous alumina for the reduction of compounds of aluminium, chromium, manganese, molybdenum, titanium, tungsten, vanadium, &c., and of the respective oxides agglutinated in some instances by the addition of gelatinous alumina in the case of compounds of magnesium, iron, tin, and zinc. Lead, thallium, and the alkali metals are reduced in brasqued iron crucibles; boron and silicon in crucibles of nearly pure silica.

Sulphides of iron, copper, and lead present together in iron pyrites are first treated with superheated steam in a closed vessel, a current of the gas being passed through the molten mass until it is free from sulphur, and the resulting oxide treated first with the quantity of hydrocarbon gas required to reduce the lead and copper only, the heat being maintained at about 2,000° F.; the temperature is then raised, and the ferric oxide reduced at a temperature of 2,500–3,000° F. Other sulphides are treated in an analogous manner.—S. B. A. A.

Improvements in the Manufacture of Steel and Ingot Iron. R. Smith Cassen, Brinsley Hill. Eng. Pat. 16,344, October 14, 1890. 4d.

THIS inventor carburises ingot iron by strewing charcoal on the bottom of the ladle, running the metal in directly from the converter, and subsequently adding a little more than the usual proportion of ferromanganese. About 5 lb. of charcoal is used per ton of metal to produce a high-grade steel capable of standing a tensile strain of from 26 to 31 tons.—S. B. A. A.

Improvements in Machinery or Apparatus to be used for the Extraction of Gold and Silver from their Ores by the Amalgamation Process. J. Harris, Sydenham. Eng. Pat. 16,694, October 20, 1890. 4d.

ACCORDING to this invention, gold or silver ores are crushed by stamps or otherwise and charged into a trough containing mercury and fitted with a series of longitudinally-corrugated rollers, which successively carry the ore down into the

mercury and finally pass it on to the discharge end of the trough. A rake is placed before this end, and serves to open up the tailings before discharge, allowing any entangled mercury to separate. The bed of the trough is depressed under the centre of each roller, and suitable mercury traps, &c., are adjusted in convenient positions.

—S. B. A. A.

Improvements in and Means or Apparatus for the Extraction of Metals from Metallic Ores or Matters containing Metals. N. Lébédoff, St. Petersburg, Russia. Eng. Pat. 17,935, November 7, 1890. 8d.

ACCORDING to this invention, metallic oxides melted or fluxed in a vessel with porous walls are reduced by the action of gases which are allowed to diffuse through the walls of the vessel. It is essential that the mixture of ore, flux, &c., be reduced to a state of perfect fluidity before treatment. The process may be conducted either in plumbago crucibles or in a reverberatory furnace the hearth of which is formed of thin slabs of plumbago or other porous material, below which the reducing gases can circulate. It is alleged that aluminium may in this way be reduced from a solution of the oxide in calcium fluoride.—S. B. A. A.

Improvements in Extracting Iron and Steel or other Metals from Ores or other Metalliferous Materials. N. Lébédoff, St. Petersburg, Russia. Eng. Pat. 946, January 19, 1891. 6d.

IRON or other ore is mixed with limestone or dolomite in the proportions required by the equations—

placed preferably on the hearth of a basic-lined open-hearth furnace, and when the mixture commences to melt a thin layer of pulverised coke, anthracite, &c. is placed on the surface of the mixture. Under these circumstances it is stated that the carbon reduces the carbonic anhydride given off by the decomposing limestone into carbonic oxide, which in turn reduces the ore. The reduction may also be effected by melting the ore on a bed composed of a mixture of limestone and carbon.—S. B. A. A.

Improvements in the Methods of Treating Blue Billy or Purple Iron Ore, Iron Sand, and Similar Substances for the Purpose of Preparing them for the Reducing Furnace. J. Bowring, Tilbury. Eng. Pat. 11,083, June 30, 1891. 4d.

FOR purposes of reduction "Blue Billy" or finely divided iron ore is well mixed with an equal weight of powdered rich coking coal, or with two parts of refractory coal, wetted with water, tar being added in a proportion determined by experiment, and the mixture coked. A hard coherent mass is said to be obtained fit for treatment in the blast furnace.

—S. B. A. A.

An Improved Converter for the Manufacture of Iron and Steel. J. Wilmotte, Chénée, Belgium. Eng. Pat. 12,165, July 17, 1891. 6d.

THIS apparatus consists of an ordinary casting ladle into which may be lowered to various depths a fire-proof block pierced by inclined pipes located in a circle and communicating with an air reservoir surmounting the block. This reservoir is connected with an adjustable slide pipe attached to the blowing apparatus. Air can thus be blown into the steel from above, and it is possible to treat small quantities of metal in the ladle by suitably adjusting the block.

—S. B. A. A.

Improvements in the Manufacture of Galvanised Iron. J. W. Richards, Philadelphia, U.S.A. Eng. Pat. 12,405, July 21, 1891. 4d.

THE inventor finds that the presence of small quantities of aluminium in the galvanising bath leads to the deposition of a highly crystalline as well as a permanently brilliant and adhesive coating of zinc. The aluminium is best added to the bath in the form of a zinc alloy containing two per cent. of aluminium, 4 oz. of this alloy being added to the galvanising bath for every ton of zinc.—S. B. A. A.

Improvements in Apparatus for Use in Electro-Metallurgical Operations. C. Hoepfner, Giessen, Germany. Eng. Pat. 13,735, September 1, 1890. 8d.

THE apparatus somewhat resembles a filter-press and consists of a number of frames separated by porous diaphragms, the frames containing alternately positive and negative electrodes. The stream of liquid enters the first frame at one side, passes to the other, and then through channels in the walls of No. 2 into No. 3, from the opposite side of No. 3 into No. 5, and so on. Similarly, a second stream of liquor enters No. 2 and passes successively into Nos. 4, 6, &c. Thus all the anode cells communicate, and all the cathode cells. The diaphragms are of parchment paper strengthened on one or both sides with a strong fabric. For use with chlorides, bromides, &c., diaphragms of asbestos or other organic substances may be used.

The inventor proposes to use the same general arrangements for battery cells, insulating india-rubber diaphragms being used to separate the various cells of the battery from one another. He appears to allow compartments of different cells to communicate, however, by the liquid filling the channels.—E. T.

XI.—ELECTRO-CHEMISTRY AND ELECTRO-METALLURGY.

PATENTS.

Improvements in Electrical Storage Batteries. E. Frankland, Reigate Hill. Eng. Pat. 4303, September 9, 1882. (Second Edition.) 6d.

THIS patent relates to methods of hardening the lead oxide used in pasting the plates of storage cells. This result is brought about by the use of some acid, generally sulphuric, which is capable of forming an insoluble or sparingly soluble salt with the oxide. In one method described the oxide is mixed with water and spread over the plate, and after drying is hardened by repeated moistenings with dilute sulphuric acid. In a second method the acids and oxides are mixed at once to form the paste. In a third method the oxide, mixed with sulphuric acid, is cast round a conductor in a suitable mould. In a fourth method the metal supports are coated with oxide by repeated dipping into the oxide-acid paste. In a fifth method solid plates are formed by casting the oxide-acid paste in a mould without any metallic conductor. In all cases the plates, after drying, are to be saturated with dilute sulphuric acid, to further harden them. Where perforated plates are used, the inventor prefers to make small holes through the pellets of active material, so as to induce better circulation of the electrolyte.—E. T.

Improvements in Secondary Batteries. J. T. Niblett, Greenwich. Eng. Pat. 14,411, September 12, 1890. 8d.

To make thoroughly compact cells, adapted for portability, &c., an outer cell and porous pot, both containing electrodes, are used. Both pot and cell are packed with flaky and spongy lead, produced by pouring melted lead from a suitable height into hot water. The electrolyte is poured into both cells and fills all interstices. Formation may be hastened by depositing spongy lead on the negative electrode. For this purpose the cell is heated and filled with water slightly acidified by nitric or acetic acid, and a strong current passed for some time. The cell is then filled with its usual electrolyte, and formation in the ordinary manner proceeded with.—E. T.

Improvements in Incandescent Electric Lamps and Leading-in-Wires therefor. B. J. B. Mills, London. From T. A. Edison, Llewellyn Park, New Jersey, U.S.A. Eng. Pat. 15,792, October 6, 1890. 8d.

LEADING-IN-WIRES of other materials than platinum have larger coefficients of expansion than glass, and during cooling after the operation of sealing in, shrink away from the glass and allow air to leak in, shrink away from the glass and allow air to leak into the lamps. The platinum wires are thicker than mere electrical reasons require since they must be sufficiently rigid to support the filament. To economise platinum and yet obtain a safe seal, the inventor supports the filament on sufficiently stout copper wires, which are sealed into the glass. These wires do not, however, pass right through the glass to the outside of the lamp, but are each attached to a short piece of very fine platinum wire, round which the glass makes a perfect seal. These short platinum wires, wholly imbedded in the glass, are attached to other copper wires which finally pass out of the lamp for making connections. The platinum required for each lamp (for half ampère lamp) is thus reduced to two short pieces, each about $\frac{1}{4}$ inch long and $\frac{3}{32}$ inch diameter, while, if anything, a more perfect seal is obtained than by the usual plan. A second, but less perfect method on the same principle is described, whereby the amount of platinum is reduced to one half that of an ordinary lamp.—E. T.

Improvements in Thermo-Electric Batteries. G. E. Gouraud, Benlah Hill. Eng. Pat. 12,330, August 6, 1890. 6d.

A SMALL block, composed of three parts of antimony, two parts of zinc, has a small wire or strip of nickel or nickeline embedded in it near each end. The wires project in a vertical direction from the horizontal top face of the block. The end to be heated is protected against fusion by a casing, usually of iron. As many of these blocks with electrodes are joined in series as are desired, and arrangements are made for heating the eased ends to a higher temperature than would be practical without protection.—E. T.

Improvements in Electrical Smelting. E. Taussig, Bahrenfeld, Germany. Eng. Pat. 12,475, August 9, 1890. 6d.

THE electric current is led into and out of the furnace by electrodes of considerable surface and made of plates preferably of the same metal as that to be smelted out. On first passing current the points of bad contact of the separate parts of the ore are heated. As these points soften and the area of contact becomes larger, more current passes and the operation goes on till the whole is melted. According to the patentee if the cross section of the furnace be one square metre, that that of the copper conductor and of the electrodes should also be one square metre.—E. T.

Improvements in and relating to Electric Batteries. E. Ottelli, Cadenabbia, Italy. Eng. Pat. 20,712, December 18, 1890. 8d.

A NARROW flat cell of wood or other light material rendered waterproof contains a second, and necessarily still narrower cell of carbon, which again contains a zinc plate, insulated from it, in solution of ammonium chloride. Chlorine is supplied from a suitable generator to the space between the wooden and carbon cells. As the result of electrolytic action, zinc chloride and ammonia formed by the action

of the zinc on the ammonium chloride, which is, however, reformed by the absorption of the chlorine which passes through the porous carbon from the outside. In a battery of such cells chlorine is to be supplied to each independently of the others.—E. T.

An Improved Method of Producing a Hermetical Seal for the Connecting Wires of the Filaments of Incandescent Lamps. F. Walter, Vienna, Austria. Eng. Pat. 7160, April 25, 1891. 6d.

THE terminal end of the lamp is provided with two small tubes, and the filament, attached to stout wires of copper or other suitable metal, is inserted from the opposite end of the lamp till the ends of the supporting wires have entered and traversed the small tubes. The end of each tube is then filled with a metallic alloy, making good electrical contact with the wire, and a small metal capsule is fitted over the tube with more alloy between it and the latter. The alloy to be employed is described in Eng. Pat. 7159 of 1891, and is such that an air-tight joint can be made between it and glass. The terminals of the lamp are the two metal capsules.—E. T.

Improvements in Secondary or Storage Batteries. S. C. C. Currie, Philadelphia, U.S.A. Eng. Pat. 9762, June 9, 1891. 8d.

THE electrodes, preferably in the shape of wires or rods, are protected with a covering of braided asbestos or other suitable material. They are then immersed in some such solution as that of zinc chloride, and converted to a greater or less depth by electrolysis into lead chloride. This lead chloride is afterwards reduced by reversal of the current into lead, when the electrodes are in a state for rapid use.—E. T.

Improvements in Galvanic Batteries. G. A. Schoth, London. Eng. Pat. 9928, June 11, 1891. 4d.

AS an absorbent material for dry batteries, the inventor uses the dried compressed moss known as "Sphagnum." The cell is made up of a zinc tube closed at the bottom by a paraffined wood stopper, and covered on the outside with calico or canvas varnished or japanned. The zinc cell contains the moss, which surrounds the carbon with its depolarising materials, and is saturated with the electrolyte.—E. T.

Improvements in Electric Batteries. W. A. Crowder, Memphis, U.S.A. Eng. Pat. 5638, August 1, 1891. (Internat. Conv. October 7, 1890.) 8d.

IN order to avoid the high electrical resistance introduced by a thick porous pad and the large diffusion or osmotic action with a thin one, the inventor employs the latter with the porous carbon electrode in close contact with it. The contact need not be perfect, as grooves, channels, or perforations may be added to allow a limited circulation of the liquid between the carbon and the porous diaphragm.—E. T.

XII.—FATS, OILS, AND SOAP MANUFACTURE.

On New Derivatives of Stearic Acid. C. Hell and J. Sadomsky. Ber. 1891, 24, 2388—2396.

THE authors obtained pure stearic acid from oil of Bassia-seed (Illipe oil), which contains much stearic acid, as well as palmitic and oleic acid, by saponification, treatment of the isolated fatty acids with alcohol, repeated distillation under vacuum, and, lastly, by fractional precipitation with magnesium acetate (Heintz' method). This acid melts at 69.2 C.—K. E. M.

PATENTS.

Treatment of Linseed and other Oils Employed in Varnishes. A. F. St. George, Redhill. Eng. Pat. 10,753, July 11, 1890. 8d.

THE linseed or other oil is floated in a thin layer on the surface of water containing hydrogen peroxide or other oxidising agent, and kept at a suitably elevated temperature, whereby it becomes bleached. The process is carried on preferably with the assistance of daylight or the electric light to further the oxidising action. A sketch of a heating chamber for conducting the process accompanies the specification.—G. H. B.

Improvements in or Appertaining to Bars, Blocks, or Tablets of Soap, or other like Soluble Substances. W. H. Thew, Liverpool. Eng. Pat. 11,358, July 21, 1890. 6d.

A block of soap is divided into sections by having a series of marks impressed on it; on each section is marked the amount of water required for the section. Drawings accompany the specification.—K. E. M.

Improvements in the Preparation of Paint Oils. J. Baptista, Philadelphia, U.S.A. Eng. Pat. 11,359, July 21, 1890. 6d.

MIXED oil, resin, borate of manganese, and linseed oil are incorporated together in specified proportions for the preparation of a drying oil termed by the inventor "Linocene." A small addition of sulphur to the oil is also included.—G. H. B.

Improved Plant or Apparatus for Extracting Oil or Grease from Granular or Pulverulent Material. W. H. Lever, J. D. Lever, and E. G. Scott, Port Sunlight. Eng. Pat. 16,025, October 9, 1890. 11d.

THE apparatus is for the purpose of using volatile solvents in the treatment of oleaginous materials, the extractions being carried on systematically in a series of closed vessels, but the fully extracted material is removed to another vessel for the recovery of the adhering solvent, the vapours from which are removed in a partial vacuum and condensed under considerable pressure. These means are specially adapted to working with such volatile liquids as tetrachloride of carbon, carbon disulphide, and chloroform. The apparatus is described in considerable detail, for the comprehension of which a reference to the accompanying drawings is essential.—G. H. B.

Improvements in the Manufacture of Soap. C. A. O. Rosell and J. C. Pennic, Washington, U.S.A. Eng. Pat. 16,059, October 9, 1890. 6d.

THE specification refers to the production of a hard potash soap, for which the harder fats and fatty acids are to be used. Any greater degree of hardness desired is to be

attained by using soda along with the potash for saponification; or a potash salt such as the sulphate, bicarbonate or sulphite may be added to the soap. The operations described are those ordinarily in use, except that potassium salts, especially the chloride, are used instead of sodium salts for salting out, &c. There are 19 claims.—G. H. B.

Improvements in the Manufacture of Iodine Soaps.
A. Seibels, Berlin, Germany. Eng. Pat. 9991, June 12, 1891. 4d.

With a view to ensure the presence of iodine in a soap uncombined with the alkalis used in the saponification, the fatty matter to be used for the manufacture of the soap is heated with iodine to about 266° F.—K. E. M.

Improvements in and relating to Lubricants for Machinery.
C. Fink, Washington, U.S.A. Eng. Pat. 10,132, June 15, 1891. 4d.

A MIXTURE composed of pulverised lime, pulverised French chalk, and carbonate of potash and water is added to various oils to give these more body for lubricating purposes.—K. E. M.

XIII.—PAINTS, PIGMENTS, VARNISHES, RESINS, INDIA-RUBBER, Etc.

Studies upon Resins. L. H. Friedburg, J. Amer. Chem. Soc. 1890, 12, 392—394.

In order to determine simultaneously the temperatures of melting kauri (copal) gum and of its vapours, 222 grms of pale but soft kauri gum, coarsely powdered, were put into a tubulated retort, into the tube of which two thermometers were inserted, one to ascertain the melting point and the other the temperatures of the vapours.

The following temperatures were observed:—

	Vapour.	Gum.
	° C.	° C.
After 55 minutes.....	151	351
After 60 minutes.....	178	341
After 65 minutes.....	175	337
After 70 minutes.....	175	335

For the first 18 minutes the retort became filled with visible fumes which then disappeared, the upper half of the retort remaining transparent to the end. The liquid distillate obtained weighed only 36 grms., at a temperature of 21° C. it consisted of two layers of 0.86 and 1.01 sp. gr. respectively. The residue, when cold, was transparent, clear and of a brilliant dark amber colour. It was completely soluble in cold spirits of turpentine. (Compare J. Amer. Chem. Soc. 1890, 12, 285—291, and this Journal, 1891, 149.)—H. S.

PATENT.

A Process for Manufacture of White Lead. G. Bisehof, London. Eng. Pat. 11,602, July 24, 1890. 6d.

In manufacturing white lead by acting with carbon dioxide on a lead oxide in the presence of suitable reagents such as acetic acid or its compounds, great difficulty is experienced in obtaining for this purpose an oxide such as will produce white lead of a clear white colour. One cause of this

difficulty seems to be that lead oxides of commerce, such, for instance, as litharge, are mixtures of several compounds of lead with oxygen which are differently acted upon by the reagents employed, so that some of these oxides become converted before others of them; and when the reaction is continued in order to convert those others, those first converted are apt to be rendered crystalline, thus greatly impairing the value of the product.

The patentee overcomes the above difficulty by partially deoxidising the crude lead oxides by exposing them at a temperature of 250—300° C. to the action of gas rich in hydrogen, e.g. water-gas, in suitable vessels. The partially deoxidised but uniform product (suboxide of lead) is allowed to cool in the reducing atmosphere of the apparatus, then afterwards exposed, after moistening with water, to the oxygen of the air; the suboxide is thereby converted into a hydrated higher oxide, $Pb(OH)_2$. This is then treated with acetic acid and carbon dioxide in the usual way, with or without admixture of sugar; the sugar having been found "useful in promoting the reaction."

XIV.—TANNING, LEATHER, GLUE, AND SIZE.

The Tannin Matters of Algarobilla and Myrabolams.

XV.—MANURES, Etc.

The Position of the Artificial Manure Industry. Chem. Ind. 1891, 14, 230—232.

THE stopping of various phosphate beds, the reduced imports from Curaçao, and the low price of crude products, accompanied with such high charge for carriage as to hinder their importation, led to a want of good crude products and a consequent rise of prices. This rise of prices was largely to the advantage of the manure industry, because, owing to the conventions, the factory prices were not able to follow the prices of crude material without increasing the enmity of a portion of the agriculturists towards the conventions.

The good harvest prospects early in 1890 and the contemporaneous want of straw, together with the ever-increasing conviction that the use of phosphoric acid was a necessity, even in moderately good farming, caused a considerably increased use of phosphatic manures; so that the factories were fully occupied in spite of the pressing offers of foreign superphosphate. The German manure trade is not only not protected by a tax, but is enumbered by the high protective tax on, for instance, the jute industry. The German manufacturers have always striven not only to produce a dry and well-powdered material, but one as perfect as possible with regard to chemical composition. The distribution of the soluble phosphates in the soil is of the greatest importance, and this can only take place when the manure contains but little iron and alumina; otherwise there will be a return of the phosphoric acid to the insoluble form. The value of phosphates when more or less free from iron and alumina is most apparent after slight rainfalls, which are able to distribute the whole of the phosphoric acid in the soil and so render it available to the crops.

If the agricultural bodies which are unwilling to co-operate with the manufacturers still continue in this course, the latter will be obliged, to the disadvantage of both, to use

inferior crude products. The manufacture, which was formerly one of the simplest, is now very difficult. The continual discovery of new phosphate beds and their rapid exhaustion, causes the manufacturer to be frequently having to deal with a new material. The lately-found Liège, Somme, and Florida-phosphate materials, however, seem to promise a greater stability.

Attention is drawn to the importance of statistics relating to phosphates being given in more detail, and not merely under the two headings of superphosphate and bone-ash, as is done at present.

It was the activity of manufacturers of Thomas slag, supported by the good results obtained with the manure, that led to a quite unforeseen increase in the use of phosphates; and as it was soon found that the two manures were not in opposition to, but rather supplement one another (each being suited for different soils) the two industries can only be a help to each other when recommending the use of phosphates.

The view held in some districts where phosphoric acid has been in use for 10 years, that its employment has been excessive, is not generally accepted, and has even been disputed by important authorities; and its adoption, without consideration, would probably lead to serious losses.

—N. H. J. M.

Alkaline Sulphides as Insecticides. Dubois. *Compt. Rend.* 1891, **112**, 1526.

SOLUTIONS of potassium or sodium monosulphide are destructive to all stages of insect life. Solutions ranging from 10 to 35 B effected the destruction of eggs and insects respectively, and the hatching of the eggs was prevented by a slight sprinkling with the solution. Even the vigorous stag-beetle succumbs to the action of the solution. These experiments point to the use of soluble sulphides for manuring with a view to the destruction of the Acridians, which devastate the crops of Algiers.—G. H. B.

The Formation of Nitrates in the Soil. A. Müntz. *Compt. Rend.* 1891, **112**, 1142—1144.

RECOGNISING the result of the recent researches on the formation of nitrous acid by the action of organisms present in the soil, the author has made a series of experiments with the object of determining the conditions under which the calcium nitrite so formed is oxidised to nitrate.

In the first series, a dilute solution of pure calcium nitrite, prepared from calcium chloride and silver nitrite, was allowed to remain exposed to the air for six months, at the end of which time it was found that no oxidation had taken place. In the next place, the action of carbonic anhydride on a similar dilute solution of calcium nitrite was studied, and it was found that the nitrous acid was liberated rapidly in the case of the gas being pure, whilst if the carbonic anhydride was diluted with an inert gas, the liberation took place more slowly. Recognising how readily free nitrous acid is oxidised by free oxygen to nitric acid the author next passed a mixture of carbonic anhydride and air through the solution of calcium nitrite, which resulted in the rapid oxidation of the nitrite to nitrate. In another experiment, soil was sterilised by heating it for half an hour to 100°, a solution of calcium nitrite was then added to it, after which it was allowed to lie exposed to the air. At the end of several days the oxidation was found to be complete. The author considers that these experiments explain how it is that the nitrate, which is formed in the soil by the agency of the nitrifying organism, becomes oxidised so readily, the soil containing, as is well known, considerable quantities of carbonic anhydride formed by the decomposition of organic matter.—J. W. L.

Thomas versus Martin Slag. Iron, October 2, 1891, 298.

THE Agricultural Experiment Bureau, of Bonn, draws attention to the fact that in the Rhine provinces Martin slag is often falsely sold as Thomas slag. In some iron-

works the Martin process for eliminating sulphur has recently been used, which method is materially different from the Thomas process. The Martin slag thus obtained does not, in the crushed state, differ in appearance from the Thomas slag; it contains, however, according to recent tests, only 12 per cent. of phosphoric acid. A sample of Martin slag analysed at the above-mentioned experimental station gave the following results:—

	Per Cent.
Phosphoric acid	11.44
Lime	40.86
Silicic acid	14.31
Sesquioxide of iron	17.85
Magnesia	9.98
Manganese	5.56
	100.00

in addition to alumina and other elements which were not specifically investigated.

Improvements in the Manufacture of Lactose or Milk Sugar. J. Y. Johnson, London. From A. L. L. Peck, Burlington, U.S.A. Eng. Pat. 13,444, August 26, 1890. *Gd.*

THIS invention provides a method for the extraction of milk sugar from whey, whereby the yield is increased, and the melassigenic action of the acid produced in the older and more lengthy processes is obviated, as is also the loss involved in the successive recrystallisations of the sugar which are necessary in these processes to free it from nitrogenous and other impurities.

The whey is neutralised either with slaked lime or chalk, heated to boiling and filtered from the partially precipitated nitrogenous constituents (proteids). The greenish, somewhat turbid liquid is evaporated to half its volume and then treated while hot with the requisite quantity (varying with different samples) of a hot concentrated solution of washing soda and alum (equal parts); any acid except nitric acid, also any one of the known precipitants of proteids "together with a solution of resnet" may be used instead of the washing soda and alum. The filtrate thus freed from proteids is again neutralised with slaked lime or chalk, passed through animal-charcoal filters, and evaporated *in vacuo* to the crystallising point. The resulting sugar forms "white fine crystals," and after washing from salts with a small quantity of ice-cold water, drying and powdering, is a marketable article.—A. R. L.

Process of Utilising the Waste of Distilleries, Breweries, Glucose and Starch Works and the like for the Preparation of Fuel. A. Parks, Martinsburg, U.S.A. Eng. Pat. 8893, May 26, 1891. *Gd.*

Improvements in Apparatus for Automatically Manufacturing Cold Syrups of a Determined Density. H. Klein and G. Dethan, Paris, France. Eng. Pat. 12,054, July 15, 1891. 6d.

THE object of this invention is to manufacture pure syrups at the ordinary temperature of a determinate density in any desired quantity, the latter depending upon the dimensions of the apparatus. The apparatus consists of a cylindrical vessel of silvered copper or other material not acted upon by the ingredients employed, and of a smaller perforated cylinder, which fits into the first and is supported by its rim. It is somewhat less than half the depth of the large cylinder. Two sieves of perforated sheet iron or gauze, surrounded by felt, cloth, flannel, or the like are placed below the smaller cylinder; these are packed with a filtering medium such as paper pulp. The larger cylinder may be constructed of glass, and in this case the smaller one is of earthenware, open at the bottom, and provided with an internal rib to support the two sieves. Air is admitted by a tube to the lower portion of the larger cylinder, but above the surface of the syrup which it contains. A gauge glass, to indicate the quantity of syrup contained in the apparatus, is attached to the side of the larger cylinder and is provided at the bottom with a three-way cock, so that its contents may be run off independently of the cylinder itself; it also contains a float, by means of which the density is determined.—A. R. L.

Improvements in Apparatus for Defecating and Evaporating Saccharine Juices. R. F. Cordero, Tachira, Venezuela. Eng. Pat. 12,058, July 15, 1891. 8d.

THE patentee describes, with the aid of drawings, an apparatus for defecating and evaporating saccharine juices, together with a furnace adapted to the same. The juice as it comes from the mill is run into pans, and thence into a series of three defecating tanks, separated from one another by partitions of unequal height, and previously charged with the defecating material. The tanks are provided with adjustable pipes reaching to the bottom, which serve to discharge the juice from one tank into the succeeding one, the last tank discharging, by a similar arrangement, into an open evaporating pan having an arrangement which causes the juice to circulate freely; this discharges into another evaporating pan, and the "molasses" ultimately passes into a crystallising tank. The defecating tanks and evaporating pans are placed over the above-mentioned furnace. The juice may be fed continuously.—A. R. L.

XVII.—BREWING, WINES, SPIRITS, Etc.

The Calculation of the Alcoholic Yield from Starchy Materials. E. Donath. Chem. Zeit. 1891, 15, 597–599.

THIS is a communication from the laboratory of the technical school at Brünn.

The calculation may be based either on the amount of starch contained in the raw material, or on the amount of saccharine matter yielded after conversion of the starch.

The yield of alcohol (Σ) may be calculated by the formula—

$$\Sigma = a \frac{\lambda m}{100} + a' \frac{p P}{100}$$

where M is the weight of potatoes or other similar material containing m per cent. of starch; P the weight of malt yielding p per cent. of dry extract; a the alcoholic yield from 1 kilo. of starch; and a' the alcoholic yield from 1 kilo. of dry extract.

The numbers given by various observers for the values of a and a' vary slightly; the best values are $a = 0.53889$ and $a' = 0.4942$.

In actual practice the amount indicated by the above formula is never reached, owing to the following causes:—

1. Insufficient crushing of the material, in consequence of which and other causes undissolved starch remains behind in the grains.
2. A portion of the fermentable matter escapes fermentation and remains in the spent wash.
3. A portion of the fermentable matter undergoes a fermentation other than the alcoholic one.
4. A portion of the alcohol produced is oxidised to aldehyde or acetic acid, or is volatilised.—A. L. S.

The Use of Saccharine in Wine.

THE *Handels Museum* of September 3rd says:—

"The *Deutsche Wein Zeitung* has taken some pains to collect the opinions of various experts as regards the use of saccharine in wine or must, and in doing so has attached particular weight to such chemical laboratories as have experience in the matter of wines. The Grand Ducal Agricultural Experimental Institution of Karlsruhe considers the addition of saccharine to wine as an adulteration if the purchaser be not informed of the circumstance. The chemical laboratory of Dr. Fresenius in Wiesbaden condemns wine containing saccharine when the presence of the latter is not declared, a sentiment also expressed by the Institution for Chemical Analyses in Mainz. The district experimental station at Speyer gives its opinion in an exhaustive paper on the use of saccharine. In every case where it has been found possible to establish clearly the fact that saccharine has been added to wine, the liquor has been unhesitatingly condemned as spurious and as contravening the laws dealing with food products. Regarding the contention that saccharine is used as a preservative, it is the opinion of Dr. Halenke that to attain this purpose it would have to be used in such quantities as would render the beverage all but undrinkable, and consequently that no expert could accept such an explanation when proffered by individuals who have added saccharine to wine. The experimental stations of Alsace-Lorraine hold similar views on the subject."

Improvements in the Treatment of Grain and Malt, and the Production therefrom of a New Product, more especially intended for Use in Brewing and Distilling or as a Food. B. E. R. Newlands, London. Eng. Pat. 13,862, September 3, 1890. 4d.

THIS product is made by soaking rice, maize, barley, wheat, malt, black malt, or the like in a solution of glucose, cane sugar, caramel, or other saccharine substances of a strength of about 28° B., and either cold or hot, as may be most suitable, until the grain has become impregnated with the solution (about eight hours). The grain is then drained and dried.—A. L. S.

Improved Method of and Apparatus for Maturing Wines and Like Beverages. E. R. Budden, London. Eng. Pat. 15,790, October 6, 1890. 6d.

THE wine to be matured is led through a coil placed in a vessel containing water heated to say 190° F.; from this it passes through a second coil immersed in a vessel of cold water and thence to a receiving vat, in which it may be kept from exposure to the atmosphere. By this process of employing a variable temperature the wine is said to be matured.—A. L. S.

Improvements relating to Brewers' and Distillers' Fermenting Vessels and Yeast Receivers. R. H. Leaker and J. H. Howell, Bristol. Eng. Pat. 17,646, November 4, 1890. 8d.

THE yeast receiver is in the form of an inverted funnel with a turned-back edge, and is suspended in the fermenting square by chains. The yeast works through

the central throat and over the sides of the receiver into the same. The barrel of the wort-circulating pump is supported in the throat of the receiver by stays, and when in action pumps the fermenting wort into the yeast receiver. The wort may be allowed to flow back into the fermenting vessel by raising the receiver a little and opening a valve at the bottom of it. The yeast is removed by a door in the side of the receiver.—A. L. S.

Improvements in Producing and Refining Spirits from Oils, and Apparatus therefor. W. S. Somers, Liverpool. Eng. Pat. 2201, February 7, 1891. 6d.

THE apparatus consists of a steam-jacketed vessel with an interior steam coil; the steam from the jacket passes into the interior of the vessel. The alcohol to be purified is placed in the vessel, and the vapours which are evolved are condensed in the usual way.—A. L. S.

Process of Utilising the Waste of Distilleries, Breweries, Glucose and Starch Works, and the like, for the Preparation of Fuel. A. Parks, Martinsburg, U.S.A. Eng. Pat. 8893, May 26, 1891. 6d.

THE hot waste (slop hot) from the still is discharged into a tank, whereby the solid portion in suspension settles, and the supernatant liquid to the extent of 60—70 per cent. of the total liquid is run off. The residuum, which is a semi-solid mass of nitrogenous material is then run into another receptacle having on the bottom, which is slatted or provided with suitable openings, a thin layer (3—12 ins. deep according to circumstances) composed preferably of fine coal, cinders, sawdust or other combustible material so that 40—50 per cent. of the remaining liquid drains off. After a few hours (when cracks appear on the surface) the waste and porous layer of fuel are thrown upon a slightly inclined slatted floor to further drain, or if desired they may be burned without having recourse to the last-mentioned operation. When the lower stratum of filtering substance is not mixed with the waste, it may consist of gravel or other loose material which must, however, be placed in pockets formed on the bottom of the tank: it is desirable to mix the waste with a certain proportion of other fuel before using. It is necessary to operate on the waste before the acetic fermentation sets in, as soon after this it undergoes putrefaction, and passes into a slimy mass from which it is impossible to separate the liquid portion, and it is desirable to work up the waste each day as it is produced, in order to avoid accumulation.—A. R. L.

Improvements in Malting Apparatus. F. Bollmann, Landsberg, Germany. Eng. Pat. 11,183, July 1, 1891. 6d.

THE perforated malting-floor rests on angular perforated air distribution channels, which are supplied with moist air through branch channels communicating with a main channel in which is placed a blower for supplying the air. Each branch channel is furnished with an air-tight door so that any section of the floor may be thrown out of use and cleaned without interfering with the rest.

Improvements in the Treatment of Grain and Malt, and the Production therefrom of a New Product more specially intended for Use in Brewing and Distilling, or as a Food. B. E. R. Newlands, London. Eng. Pat. 13,862, September 3, 1890. 4d.

See under XVII., page 843.

Improved Malted Food Preparations. W. Geddes, Oldham. Eng. Pat. 15,981, October 8, 1890. 4d.

THE inventor claims the preparation of "malted marmalade," "malted preserves," "malted jellies,"—adapted for dyspeptic persons. The food materials are mixed with an extract of malted barley, wheat, &c. prepared preferably *in vacuo*, a small quantity of gelatin together with the "desired flavouring or colouring" being added to the finished product.—A. R. L.

Improvements in the Method of Treating Bananas for Use in the Preparation of Food and Drink. M. A. E. Schneider, Baden-Baden, Germany, and R. H. Coall, London. Eng. Pat. 16,857, October 22, 1890. 6d.

THIS specification relates to the preparation of meal from banana fruit to be used either alone or in admixture with other "nutritious or medicinal materials" in the preparation of food and drink for infants, invalids, &c. The banana fruits are peeled and heated on "wire grills or gratings" in an oven or hot chamber at about 35° C. for about eight hours; they are next transferred to a dry room and kept there for at least 24 hours, and then again heated in the aforesaid manner for 5 hours at 55—60° C.; after which they are cut into pieces, one centimetre in length, and carefully heated in a coffee roaster or other suitable apparatus over a quick fire until they are of a uniform dark brown colour. When cool the pieces are bruised and ground in a mill to a fine brown flour. The latter forms an "excellent substitute for coffee," and an "excellent food for children and invalids" may be prepared by mixing the banana flour with maize corn flour.—A. R. L.

Method of Preserving Grain Fodder. R. R. von Gunesch and C. Beutle, Vienna, Austria. Eng. Pat. 3498, February 26, 1891. 4d.

GRAIN fodder, such as oats, maize, and barley, is freed from dust and foreign seeds in a cleaning machine, crushed (not

ground) between smooth rolls, and mixed with solutions of sugar, molasses, dextrin, maize-gluten, gelatin, or gum arabic, suitable proportion being usually 100 kilos. of grain fodder to 1—10 kilos. of the binding material. It is then subjected to a pressure of 500—600 atmospheres in a hydraulic press, whereby it is reduced to about one-third of its original volume, and the cakes thus formed are dried in a chamber through which air circulates. It is claimed that the invention not only secures the preservation of the grain fodder but also facilitates its packing and transport by reducing its bulk.—A. R. L.

Improved Method of and Process for the Preparation of Condensed Milk. C. Lesser, Warsaw, Russia. Eng. Pat. 5196, March 24, 1891. 4d.

MILK is freed in a centrifugal machine from impurities and separated into cream and skimmed milk. The caseine is carefully precipitated from the latter by means of rennet or other suitable precipitant, or by means of a centrifugal machine; it is then condensed at a temperature not exceeding 75° C in a vacuum apparatus, having a sight of yellow or red glass "which admits red or yellow light," as the inventor finds that the more refrangible rays have a deleterious action on the miscibility with water of the "condensed product." Care must be taken that during "condensation" the acidity does not exceed a limit of 5.5 (Sohxlet-Henkel), and to this end a certain quantity of easitic or carbonated alkalis or of alkaline earths are added to the milk. The "condensed product" is now re-mixed with the cream and with milk sugar. It is urged that by this process the complete miscibility of the finished product with water is ensured.—A. R. L.

Improvements in Centrifugal Apparatus for Testing Relative Volumes of Mixtures of Liquids of Different Specific Gravities. J. Laidlaw, Glasgow. Eng. Pat. 10,492, June 20, 1891. 6d.

See under 1., page 822.

(B).—SANITARY CHEMISTRY.

Action of Water on Lead Pipe. E. Waller. J. Amer. Chem. Soc. 1891, 13, 176—178.

Two waters from the mountain region of Kentucky were examined, and, since the intention was to use the waters for drinking purposes, their action on lead pipe was tried.

Total solids are thus stated in parts per 100,000.

—	I.	II.
NaCl	0.051	0.092
K ₂ SO ₄	0.284	0.263
Na ₂ SO ₄	0.157	0.093
Na ₂ CO ₃	0.032	0.017
CaCO ₃	0.556	0.404
MgCO ₃	0.501	0.346
Fe ₂ O ₃ and Al ₂ O ₃	0.107	0.180
SiO ₂	0.912	0.957
Organic matter (by difference) ..	0.800	0.548
Total	3.400	2.900

Samples of the waters were placed along with pieces of filed and scraped lead pipe in bottles of about 300 cc. capacity. After standing for about 20 hours, both bottles showed a slight white precipitate, which was proved to contain lead. The bright surfaces became dull. No lead was detected in solution. The waters and precipitates were poured off and the pieces of lead rinsed, after which they were treated with fresh portions of the waters; at the end of 24 hours very little separation had taken place in the No. I. water, but a considerable separation in No. II. After a second removal of the sediment and water, another 24 hours with fresh samples of the waters produced scarcely any result in the case of No. I., whilst No. II. showed as much sediment as before; on continued standing a little separation took place in the case of No. I., but the sediment in No. II. bottle continued to increase very considerably. The action corresponds almost exactly to the action of Loch Katrine water on lead in open vessels. Water No. I. in the closed bottle acts in very much the same way as the Loch Katrine water in closed vessels. The analysis of Loch Katrine water shows about the same proportion of solids, though the salts are different in their respective amounts; in Loch Katrine water they are, in parts per 100,000, as follows:—

Organic matter	1.285
CaSO ₄	0.544
CaCl ₂	0.206
Alkaline chlorides	0.619
MgCO ₃	0.300
SiO ₂ and phosphates	0.243
Fe ₂ O ₃	Traces
Total	3.206

—T. L. B.

PATENTS.

Manufacture of Illuminating Gas and other Useful Products from Refuse of the Kind known as Town's Refuse. F. Seudder, London. Eng. Pat. 10,313, July 3, 1890. 4d.

THE refuse, after being screened and hand picked to remove non-combustible material, is charged, together with an admixture of about 10 per cent. of coal or coke to ensure proper combustion, into a gas producer of any suitable construction designed to produce either ordinary producer-gas or water-gas, and it is burnt with air or air and steam. It is also usually advantageous to mix with the refuse a suitable proportion (from 1 to 2½ per cent.) of lime or an alkali to act as a flux and to facilitate the production of ammonia from the nitrogenous matter in the refuse. For the latter purpose a producer constructed to make water-gas is the most suitable kind. In carrying out the process it is advisable to use a combination of two producers, the water-gas formed by the steam descending through the incandescent charge of the first producer being then passed through the second producer, which is preferably charged with coke. In this way any steam and hydrocarbons carried forward by the water-gas from the first producer become decomposed.

The gases after leaving the second producer are then cooled to a temperature of about 300° F. by passing through a cooler or condenser preferably cooled by air, and they are then led through strong sulphuric acid of about 140° Tw., which absorbs the ammonia contained in the gases, whilst the carbonic oxide, hydrogen, and other unabsorbed gases are passed finally into a suitable reservoir or conduit for use for illuminating or heating purposes. The temperature to which the gases are cooled, viz., about 300° F., is such that the sulphuric acid is not volatilised, but is sufficient to prevent the condensation of water in the sulphuric acid. The sulphate of ammonia crystals that are formed are removed from time to time, and a corresponding quantity of fresh sulphuric acid is run into the saturator to maintain the strength of the acid.—H. S. P.

Improvements in Sterilising Water and other Liquids, and Apparatus therefor. H. Rouart, Paris, France. Eng. Pat. 14,051, September 6, 1890. *8d.*

The process consists in heating the liquid to be sterilised in a strong closed vessel to 120° C., and subsequently cooling it. By this means the dissolved gases in the liquid under treatment are retained, subsequent aeration is rendered unnecessary, and thus the danger of fresh infection is minimised. Several forms of apparatus in which the operation can be most conveniently carried out are described. For drawings and details of these, the original specification must be consulted.—H. T. P.

Improvements in the Treatment of Sewage. A. O. Jones, Harrogate, and S. Fox, New Wortley. Eng. Pat. 14,253, September 10, 1890. *6d.*

The solid portion of the sewage to be treated is separated from the liquid portion and charged, either alone or in admixture with from one-fourth to four times its own weight of some carbonaceous material, such as coal, coal-dust, or smudge, coke, town's refuse, sawdust, or soot, into an ordinary furnace for the production of water- or producer-gas. The furnace is manipulated in the usual way, air and steam being admitted alternately; only, when the sludge is to be used alone, the furnace is first heated by a preliminary charge of coke or coal. The liquid portion of the sewage is heated in a boiler, the steam and noxious gases given off being employed to feed the gas-producing furnace. The water- or producer-gas obtained is purified as usual by means of scrubbers and purifiers.—H. T. P.

Improvements in the Preparation of Agents for Use in the Purification of Sewage and other Polluted Water, by Precipitation; and Improvements in the Treatment of Sewage and other Polluted Water in order to Effect the Purification thereof. J. W. Slater and "The Native Canano Company (Limited)," London. Eng. Pat. 17,453, October 31, 1890. *6d.*

The following preparations are employed for the purpose of purifying sewage, &c. :—

A.—Clay, loam, or non-calcareous earth, 100 parts by weight; semi-peat, 100 parts; basic iron slag, Redonda phosphate or other phosphate, 10 parts; carbon (if used), 10 parts; and water in sufficient quantity to produce a thin paste.

B.—A saturated solution of crude aluminium chloride, or an equivalent quantity of a solution of aluminium sulphate, 100 parts by weight; solution of copper slag in crude hydrochloric acid, "in such quantity as to introduce into the mixture copper, one part by weight." Instead of the copper slag, any other waste, containing an equivalent amount of copper, may be used. Or, in place of the copper solution, a solution of manganous sulphate or chloride, 80 parts by weight; water, 10 parts, also by weight.

In treating sewage, &c., a quantity of A. is added thereto, and well stirred in; a quantity of B. is then added, by which means the impurities are precipitated. For average sewage, 3 lb. of A. and 1½ lb. of B. per 10,000 gallons, are about the right amounts to use. In other cases the quantities to be employed are easily found by a small trial experiment.

In regard to the above mixtures the following remarks must be made. By "semi-peat" is meant a naturally occurring deposit of vegetable matter in course of conversion into peat, but which still retains, to some extent, its vegetable structure, and contains only traces of erenic and apocrenic acids. Semi-peat is found overlying the clay along the banks of the Lower Thames and Medway (for instance, at East Greenwich). Carbon is only added to the mixture A. when the liquid to be treated is stronger than average sewage, or contains much tan liquor.—H. T. P.

A Method of and Apparatus for the Treatment and Disposal of Sewage. C. W. Chancellor, Baltimore, U.S.A. Eng. Pat. 4243, March 10, 1891. *8d.*

This apparatus is more particularly suitable for the treatment and disposal of household sewage. It consists of a cylindrical strainer, a receiving tank, a settling or precipitating tank, and a filter. The vessels are all air-tight, and are connected together in series, the last three being placed on the same level; whilst the strainer is fixed on the top of the receiving vessel. The soil pipe from closets, &c., is connected directly to the strainer. The solid portion of the sewage discharged into the latter finds its way through a trap at the bottom into the receiving vessel, which is filled with water, where it settles. The liquid portion of the sewage passing through the walls of the strainer flows through a pipe into the settling tank. Before entering the settling tank a small quantity of the fluid is made to pass through a box containing some solid disinfectant, such as quicklime, sulphate of iron, or alum. The inlet and outlet tubes of the precipitating vessel are so arranged that the suspended matters have time to settle before the liquid passes on to the filter. The filter simply consists of a cast or wrought iron vessel fitted with a perforated false bottom, between which and a perforated shelf fixed some distance higher up, the filtering medium is disposed. The filtered liquid finally leaves the filter through a pipe near the top. For drawings and details of the apparatus the original specification must be consulted.—H. T. P.

(C).—DISINFECTANTS.

The Employment of Carbon Disulphide against the Ravages of the Phylloxera. A. F. Marion and G. Gastine. Compt. Rend. 1891, 112, 1113—1117.

The authors have made further experiments on the value of carbon disulphide as an insecticide, especially in the case of the phylloxera of the vine. Different quantities of carbon disulphide, both pure and also mixed with some non-volatile ingredient, have been injected into different descriptions of soil and determinations made of the extent of the diffusion, as measured from the point of injection. Also in another series of experiments the toxic effect of the carbon disulphide vapour on the phylloxera has been experimented on. 100 tubes, each containing fragments of the vine roots, which were attacked by the insect, were placed in series of 25 in different kinds of earth and subjected to the action of carbon disulphide vapour. At the end of a certain period the root fragments were withdrawn and examined. From the relation which the still living phylloxera bore to those which had been killed, the authors found, what they term, the "insecticide coefficient." In the opinion of the authors, mixtures of such substances as gas-tar or rosin oil, and carbon disulphide, made with the object of reducing the rate of volatilisation of the latter in the earth, are a false economy, since a considerable proportion of the carbon disulphide is retained permanently by the tar or oil.

In the employment of vaselin for this purpose, the case is just the same, and it is only during the first short period after the injection that the vapour of the carbon disulphide is present in sufficient amount to act as an insecticide.

The authors consider that the disulphide should be employed by itself, the quantity being varied for different classes of soil, from 220—250 kilos. per hectare for light and readily permeable soils, whilst for heavy clays the quantity must be increased to 300—350 kilos. They also consider it economical to apply the carbon disulphide in two portions, a few days being allowed to elapse between the injections. It is an excellent practice to inject 5 or 6 cc. of the disulphide at a distance of some 10 cm. from the vine stock and at a nearly equal depth.—J. W. L.

The Employment of Carbon Bisulphide for the Destruction of Atmospheric Germs. H. Quantin. Compt. Rend. 1891, 112, 1283—1284.

Carbon bisulphide when dissolved in a vegetable oil is immediately precipitated as an emulsion by the addition of

water (free from calcium salts) made slightly alkaline by sodium carbonate. A milk is thus obtained, the toxic properties of which are in direct proportion to the quantity of carbon bisulphide present, and which can be brought up to 60—80 grms. per litre. On standing, some of the carbon bisulphide separates from the emulsion, but it is readily taken up again on stirring the mixture. The oil, beyond serving as a solvent for the carbon bisulphide, also is advantageous in restricting its rate of evaporation. This method of obtaining an emulsion can be employed in many ways for antiseptic purposes. The carbon bisulphide can be saturated with sulphur, of which it will take up one-third of its own weight, before making the emulsion; or solutions of sulphur in heavy oils, boiling below 200° C., can be similarly prepared. Further, an emulsion of such a mixture as carbon bisulphide and carbonate of copper can be employed as an antiseptic. The experiments tried with the carbon bisulphide, an emulsion containing 50 grms. to a litre of oil being employed, were in every way satisfactory. —C. A. K.

The Employment of Carbon Bisulphide dissolved in Water against Phylloxera. A. Rommier. Compt. Rend. 1891, **112**, 1330—1333.

THE paper contains a short summary of the experiments made in France since 1875 on the use of aqueous solutions of carbon bisulphide for exterminating phylloxera. The solubility of carbon bisulphide is a little more than 2 grms. per litre at the ordinary temperature according to the author, whilst Chancel and Parmentier found it to vary from 2 grms. per litre at 3·4° C. to 1·05 grms. per litre at 40° C. These aqueous solutions of carbon bisulphide have in all cases been most successful in combating the phylloxera pest. —C. A. K.

Alkaline Sulphides as Insecticides. Dubois. Compt. Rend. 1891, **112**, 1526.

See under XV., page 842.

XIX.—PAPER, PASTEBOARD, Etc.

On Sizing Paper with Ammonium Albumen. Dingl. Polyt. J. **279**, 298—300.

AMMONIUM albumen (compare Dingl. Polyt. J. **275**, 71, and this Journal, 1890, 320) obtained from milk, is soluble in water, and this liquid may be mixed with rosin-size solutions, starch, colouring matters, &c. in varying proportions. In many respects its properties are similar to rosin-size, the albuminates being precipitated by treating the solutions with aluminium sulphate. The chief advantages of ammonium albumen as a sizing material consist in its being absorbed in large quantities by the fibres and in its imparting to the paper increased strength and durability in addition to gloss and smoothness. It yields better results than animal size, because all albuminates are precipitated by treatment with aluminium sulphate, and what is not absorbed by the fibres coats their surface, whilst animal size is less effective and much more expensive. In many instances it is advisable to mix ammonium albumen with rosin-size (in varying proportions), and so combine the good qualities of both these sizing materials.—H. S.

PATENT.

Improvements in Apparatus for Separating Iron from Paper Stock. H. H. Lake, London. From B. D. Rising, Mittineague, and C. H. Atkins, Palmer, U.S.A. Eng. Pat. 10,696, June 23, 1891. 6*l*.

IN the bottom of the trough through which the pulp has to travel from the vats to the paper-making machine, is mounted an electro-magnet, whose poles project through into the trough and extend from side to side across it. The poles thus form two successive ridges across the bottom, over which the pulp must flow, and attract and retain any magnetisable particles in the latter. Ripples and depressions, with the use of mercury, are dispensed with. The poles may form simple ridges or may be of any desired shape and number, and may be excited by more than one electro-magnet if desired.—E. T.

XX.—FINE CHEMICALS, ALKALOIDS, ESSENCES AND EXTRACTS.

Quinine and its Manufacture. C. Zebel. Chem. Zeit. 1891, **15**, 735—736.

AFTER an historical sketch of the quinine industry, the author turns to the method of extraction of the bark, for which purpose paraffin oil is now employed. The finely-powdered bark is ground to a thin paste with lime, caustic soda, or sodium carbonate, and extracted with warm paraffin oil. On standing the oil separates, when it is run off and shaken with sulphuric acid; this solution is boiled, and whilst boiling is neutralised with sodium carbonate and allowed to cool. Quinine sulphate crystallises out on cooling, whilst cinchonidine, cinchonine, and quaidine remain in solution as sulphates. The quinine sulphate is purified by recrystallisation after treatment with animal charcoal. The mother-liquor containing the other alkaloids is treated with caustic soda, and extracted with weak alcohol, when of the three bases precipitated by the alkali, quinine and cinchonidine are dissolved, whilst cinchonine is left behind; the two former can then be separated by means of their neutral tartrates, that of quinine being considerably the more soluble.

Chemically pure quinine is manufactured by preparing the acid sulphate, which after undergoing sufficient purification is reconverted into the neutral salt. The consumption of quinine amounts to 200,000 kilos. annually. The Ceylon bark contains from 2·4 per cent. of quinine sulphate; Java bark 4—9 per cent. and even up to 13 per cent. The more recent cultivations of cinchona bark in Peru and Bolivia are of special importance; such bark yields about 4—5 per cent. of sulphate of quinine.—C. A. K.

Amaryllyne and Belamarine; two New Alkaloids. K. Fragoer. Ber. 1891, **24**, 1498—1500.

IT is well known that the plants belonging to the family Amarylidae are poisonous; the tubers both of *Amaryllyis formosissima* and of *A. Belladonna* produce vomiting and even death.

The former, which is a native of South America, contains a new alkaloid, *Amaryllyne*, which can be extracted from the tubers by means of alcohol. After distilling off the solvent the residue is washed with water, the resulting solution precipitated with sodium carbonate, and the precipitate extracted successively with ether and with chloroform.

After evaporation a brown-red residue remains, which is purified by dissolving in acidulated water, neutralisation, extraction with chloroform, and crystallisation from strong

alcohol, from which last the alkaloid separates in small clusters of needle-shaped crystals. It is slightly soluble in water, readily in ether, alcohol and chloroform, and gives characteristic precipitates with most of the general reagents for the alkaloids. Concentrated sulphuric acid gives a dark red-brown colouration, which turns gradually brown; this brown solution becomes green on the addition of three drops of water. When heated, the amarylline begins to discolour at 190° C. and melts at 196° C.

The tubers of *Amargyllis belladonna*, which is a native of the islands in the Caribbean Sea, contain the alkaloid *Belamarine*, which can be extracted by means of hot alcohol. The residue, after evaporating off the alcohol, is taken up with water, and the aqueous solution precipitated by sodium carbonate, when a voluminous yellow-brown precipitate is obtained, which is purified by repeated crystallisation. The alkaloid forms long, colourless needles, readily soluble in chloroform, ether, and alcohol, and which melt at 181° C. The salts give characteristic precipitates with the usual reagents for the alkaloids, and also with other reagents. The author intends to continue the study, both chemical and physiological, of the two new alkaloids.—C. A. K.

Synthesis of Oxygenated Pgridine and Piperidine Bases. A. Ladenburg. Ber. 1891, 24, 1619—1628.

The author has already shown that the aldehydes react with picoline to form alkalines with the separation of water (Ber. 1889, 22, 2583).

α -Picoline, when heated to 120° for 10 hours with paraform aldehyde in molecular proportions, water being added to the mixture, yields α -picolylalkine—

a liquid boiling at 114°—116° C. under a pressure of 9 mm. That it is an alkaline is shown by its forming a benzoic ester, $C_8H_7(CH_2CH_2O.C_6H_5)N$, a weak base, platine and auric double chlorides of which were prepared and analysed. The free base could not be obtained in a crystalline state. On oxidation α -picolylalkine forms picolinic acid; a pyridyl acetic acid could not be obtained. α -Picolylalkine results when the picolyl compound is treated with sodium and absolute alcohol. It is a liquid boiling at 234.5° C. (corr.). The hydrochloride is hygroscopic, whilst the benzoyl compound forms a hydrochloride which crystallises in colourless plates. In this latter it is not the hydrogen of the imido-group that has been substituted, since it forms a nitrosamine. The substitution of the hydrogen of the imido-group by methyl is attended with considerable difficulties, and it cannot be effected by any of the ordinary methods. It can, however, be carried out successfully by heating the α -picolylalkine in aqueous solution with a large excess of the potassium salt of methyl sulphuric ester on the water-bath for 12–24 hours. The product thus obtained possesses a constant boiling point, but nevertheless still contains some unchanged α -picolylalkine, from which the methyl compound is separated by converting the latter into the mercuric chloride double salt, which is with difficulty soluble and readily purified by recrystallisation from hot water. This salt melts without decomposition at 214° C., and has the composition $C_{10}H_{12}NO.HCl.5HgCl_2$. From it the free base is readily obtained as a colourless syrupy liquid, possessing a slight smell and boiling at 223.5° C. (corr.). It is readily soluble in water and alcohol, less readily in ether, and only solidifies slowly in the cold. The gold double chloride of the base is fairly soluble and forms small crystals resembling those of sal-ammoniac, and melts at 169°—170°. Further, this n -methyl- α -picolylalkine—

reacts with methyl iodide to form an ammonium iodide from which the corresponding chloride and its gold and platine double chlorides were prepared. Since the base resembles tropine closely both constitutionally and in its properties, differing, however, in having two additional hydrogen atoms in the ring, the name *Hydrotropine* is proposed for it. When

warmed with tropic acid and hydrochloric acid an alkaline results, which, like atropine, has a mydriatic action on the eye. Since the above relationship of hydrotropine to tropine exists, the author attempted to prepare the latter from the former by oxidation. The resulting body, called *Paratropine*, has the formula $C_{11}H_{13}NO$, but is not identical with the base obtained from atropine, in fact does not resemble it very closely in physical properties. An alkaline solution of potassium ferrieyanide was employed as the oxidising agent, the resulting base being isolated by means of its gold double chloride. The free base is a colourless liquid boiling at 200°—203° C. (almost 30° C. lower than the boiling point of tropine), and which shows no tendency to crystallise at a low temperature. It has strongly alkaline properties, and forms characteristic double chlorides with platine, auric, and mercuric chlorides, which melt at 195°—197° C., 181°—182° C., and 225° C. respectively. Analyses of all these salts are given. A small quantity of a difficultly soluble base was obtained by heating paratropine with tropic acid and hydrochloric acid, and which has a similar mydriatic action to atropine.

These experiments are being continued with the view of preparing tropine and atropine synthetically.—C. A. K.

Tropine. A. Ladenburg. Ber. 1891, 24, 1628—1633.

The synthetical experiments conducted by the author with the view of preparing tropine and atropine (see previous abstract) have led to the desirability of studying the properties of tropine and of its salts more minutely. Full crystallographic measurements of the gold and platine double chlorides of tropine are given. The mercuric double chloride melts at 246° C., and blackens before melting; it has the composition $C_8H_9NO.HCl.6HgCl_2$. A short discussion of the proposed constitutional formulae for tropine follows, in which the author shows that the di-basicity of tropine acid does not overthrow the formula suggested by him, as stated by Liebermann (Ber. 1891, 24, 515).

—C. A. K.

A New Alkaloid from Conium Maculatum, its Constitution and Attempts to Synthesise it. A. Ladenburg and G. Adam. Ber. 1891, 24, 1671—1676.

The authors have investigated the nature of the new alkaloid isolated by Merck from *Conium maculatum* (this Journal, 1891, 481).

It is a strong base having an alkaline reaction and forming readily soluble salts with acids. It melts at 100°—102° C., but sublimes before melting in fine needles; the base boils at 229°—231° C., and solidifies to a crystalline mass at once on distillation. Analysis points to the formula $C_{11}H_{17}NO$, whence the alkaloid is isomeric with conhydrine, with which it shows a marked analogy; for this reason the name of *Pseudo-conhydrine* is proposed for the new base. It dissolves readily in water, alcohol, ether, and benzene, and is optically active, having a rotatory power $\alpha_D = +1.30^\circ$. It is a secondary base and forms an oily nitrosamine. The hydrochloride forms colourless hygroscopic crystals, having the composition $C_{11}H_{17}NO.HCl$; the hydrobromide is stable in the air. Pseudo-conhydrine heated with amorphous phosphorus and hydriodic acid in a closed tube to 150° C., forms an iodide $C_{11}H_{16}NI$, which when treated with hydrochloric or sulphuric acid yields a base, which was obtained however in too small a quantity to be identified. Nevertheless this reaction is considered by the authors to point to the fact that pseudo-conhydrine, like conhydrine and tropine, contains a hydroxy-group and belongs to the class called "alkalines." Ladenburg has shown that the analogy of picecolylmethylalkine to conhydrine points to one of the two following formulae for the latter:—

or

Since pseudo-conhydrine is isomeric with conhydrine it is not unnatural to suppose that it possesses one of the above

two formulæ. To put this supposition to the test the authors prepared the second of the above bodies synthetically, viz.:— α -lupetidylalkine starting from α -lutidylalkine

which was obtained by the action of formaldehyde on α -ethylpyridine. This body is a liquid boiling at 128° — 130° C. and forms characteristic platonic and auric double chlorides. When reduced by sodium in absolute alcohol solution it is converted into the α -lupetidylalkine—

which although resembling pseudo-conhydrine in smell, boiling point, and solubility, differs from it markedly in its much lower melting point, considerably below 0° C., and in its not forming crystalline salts. It boils at 232° — 234° C. The action of phosphorus and hydriodic acid is also different, and no crystalline iodide results, but a body which when distilled with alkali yields a base having the formula $C_6H_{13}N$ —an allylpyridine or conicine. It is evident that lupetidylalkine is identical with neither conhydrine nor with pseudo-conhydrine: the constitutional formulæ of the two latter therefore still remained undetermined, and the two formulæ suggested above are insufficient unless one of the three isomers contains an isopropyl group.—C. A. K.

The Formation of Inactive Tartaric Acid by the Oxidation of Phenol with Potassium Permanganate. O. Doebner. Ber. 1891, 24, 1753—1757.

A SOLUTION of phenol, neutralised by caustic soda when oxidised in the cold by potassium permanganate yields oxalic acid, inactive tartaric acid, a large quantity of carbon dioxide, and a yellow-brown amorphous body, the composition of which could not be ascertained. From 90 grms. of phenol, 9 grms. of the calcium salt of inactive tartaric acid, 24 grms. of calcium oxalate, and 5 grms. of the amorphous substance result.

The formation of the two acids may be expressed according to the following equation:—

a decomposition which, in the opinion of the author, is entirely in accordance with Kekulé's benzene formula, but opposed to the prism and to the diagonal formulæ.

The bearing of this on the double linkages in the benzene ring is discussed. Further experiments on similar lines are in progress.—C. A. K.

The Constitution of 5-membered Ring Systems. E. Bamberger. Ber. 1891, 24, 1758—1764.

See under IV., page 828.

The Action of Acid Alkaline Sulphites on Cinnamic Aldehyde. F. Mensler. Ber. 1891, 24, 1805—1807.

WHEN cinnamic aldehyde is shaken with acid sodium or potassium sulphite, the addition product separates out, which when boiled with water is decomposed according to the following equation:—

The acid sulphite of sulpho-cinnamic aldehyde thus formed is more readily obtained by treating 1 molecule of the aldehyde with 2 molecules of a hot concentrated solution

of the acid sulphite; on evaporation a crystalline residue results, which is purified by recrystallisation from water. These salts regenerate the aldehyde on dry distillation or when boiled with caustic soda; boiled with dilute sulphuric acid, sulphur dioxide is evolved, whilst the sulphonic acid of cinnamic aldehyde remains in solution. This latter body, which has the formula $C_6H_5 \cdot C_2H_3(\text{SO}_2 \cdot \text{OH})\text{COH}$, is isolated by converting it into the hydrazone which crystallises from alcohol in yellow plates, melting with decomposition at 165° — 166° . The hydrazone when treated with caustic soda is converted into the hydrazone of cinnamic aldehyde.

From these reactions the close analogy in the behaviour of cinnamic aldehyde and of acrolein with acid sulphites is apparent.—C. A. K.

Morrenine and Morrenol. P. Arata and C. Gelzer. Ber. 1891, 24, 1849—1853.

Morrenia brachystephana is one of the American *Asclepias* which grows throughout the Argentine Republic, where it is known under the name of "*Taxis*." It is largely grown by the Indians and Gauchos for the sake of the silk hairs which the fruit contains and which is used as vegetable silk. The rich sap of the rhizoma and of the fruit is made use of in medicine, especially as an aid for the flow of milk in the case of women lacking a milk supply. The daily dose is 30 grms. The infusion is yellow and thick and has a sweetish taste with a bitter after-taste. It is not unpleasant to take, but at first produces slight vomiting and a little headache; afterwards increased perspiration is noted, but otherwise the system is unaffected.

The authors have investigated the chemical nature of the root and fruit of this plant. The root is of a dark yellow colour and has a specific gravity of 0.631, contains 9.06 per cent. of water, and 9.30 per cent. of ash. Ether extracts an aromatic smelling mixture of chlorophyll, resin, fatty acids, and wax-like bodies, but the extract contains no alkaloid. The residue after extraction with ether, when extracted with alcohol yields a yellow solution which contains an alkaloid, which latter is best isolated by macerating the finely divided root for 3—4 days with 2 per cent. hydrochloric acid and treating the resulting solution after concentration with a slight excess of calcined magnesia and evaporating the whole to dryness. The residue thus obtained is exhausted with alcohol, the solvent evaporated off and the residue again taken up with either chloroform or amyl alcohol. A dark red gelatinous mass having a sharp smell and a very bitter taste remains after distilling off the solvent. It is soluble in water, melts at 106° C., and gives all the general reactions for the alkaloids. The name "*Morrenine*" is proposed for the new alkaloid. No analytical data were obtained, owing to lack of material.

The sap of the fruit of *Morrenia brachystephana* consists of a yellow-white milk, having an aromatic smell and which coagulates on standing. The liquid separated from the coagulated mass contains the alkaloid morrenine, whilst the residue dissolves in warm alcohol to a pale yellow-coloured solution from which a white crystalline substance separates on standing. This product is insoluble in water, soluble in cold sulphuric acid with a red colour and melts at 168° . Analyses point to the formula $C_{14}H_{25}O$ or to $C_{15}H_{21}O$. The name "*Morrenol*" is proposed for this substance, which is being further investigated.—C. A. K.

Preparation of Catechol. H. Gutknecht. Chem. Zeit. 1891, 15, 959.

CATECHOL has for a long time been neglected by manufacturers of dyestuffs on account of supposed difficulties in its preparation. A useful product may however readily be obtained from catechu if the use of unnecessary heat and reagents is avoided. Commercial catechu is cut into large pieces with wet knives or axes, softened in cold water, well kneaded, filtered cold through woollen cloths and the residue washed with cold water. The catechu-tannin passes into solution, the residue containing the catechol is dissolved a little at a time in hot water, filtered through

woollen cloths, and the solution cooled as speedily as possible. The catechol is thus precipitated in yellowish white needles. The filtration of the hot solution presents some difficulties on account of the slimy consistency of the residue. The catechol may be purified by recrystallisation or decolourised by adding lead acetate drop by drop to the warm solution. If the catechu is directly treated with hot water and filtered, the cold mass loses its sliminess and can more easily be worked; the yield of catechol is however about 20 per cent. less. The catechu-tannin should be useful in cotton dyeing as it yields clearer shades than ordinary catechu. Catechol is useless as a dye for cotton, but when treated with weak acids, preferably boric acid, or with small amounts of acid salts at 100°, it is converted into an uncrystallisable product which yields a clear green colour with cotton tissues.—S. B. A. A.

Bismuth Salicylate. H. Causse. *Compt. Rend.* 1891, **112**, 1220—1223.

In order to prepare bi-muth salicylate by the double decomposition of a bismuth salt and an alkaline salicylate, it is necessary to dissolve the former in acid, with the result that a mixture of the salicylate with salicylic acid is obtained. In order to avoid this, the author prepares the salt in the presence of ammonium chloride, which has the power of keeping the bi-muth salt in solution without any fear of dissociation and precipitation of a basic salt taking place. 100 grms. of sub-nitrate of bi-muth are dissolved in hydrochloric acid (concentrated) and the solution treated in the cold with 1 litre of a saturated solution of ammonium chloride; to this is then added a mixture of 120 grms. of sodium salicylate and 500 grms. of a saturated solution of ammonium chloride. On standing, the bi-muth salicylate separates out in the form of a voluminous crystalline powder, closely resembling dehydrated quinine sulphate in appearance. It is filtered off, washed, and dried at the ordinary temperature. Analysis points to the formula $\text{Bi}(\text{C}_7\text{H}_5\text{O}_3)_3 + 4 \text{H}_2\text{O}$; it is insoluble in and unacted upon by cold water, whilst boiling water, acids, and alkalis decompose it with the separation of salicylic acid or of a salicylate. It is also readily decomposed by absolute alcohol, and on heating when the decomposition begins at 50° C.—C. A. K.

Quinethyline, a Homologue of Quinine. E. Grimaux and A. Arnaud. *Compt. Rend.* 1891, **112**, 1364—1367.

THE authors have shown in a previous communication (this Journal, 1891, 723 and 790), that quinine is the methyl ether of euphene, and the name of "quinines" is proposed for all derivatives of euphene having the general formula $\text{C}_{15}\text{H}_{21}\text{N}_2\text{O}_2\text{OR}$ where R is a substituting group. Thus ordinary quinine is the first member of this series, and the body described in the present memoir the second member, viz., the ethyl ether of euphene or quinethyline. The salts of euphene previously prepared were found to contain small quantities of quinine salts, and in order to obtain the former in a pure state the acid sulphate is first converted into the neutral sulphate in aqueous solution, the latter separated by crystallisation, redissolved in boiling water, and the solution treated with an excess of caustic soda. The euphene is first precipitated, and then redissolved by the alkali, whilst the quinine remains suspended in the solution and may be extracted either by means of ether or of chloroform. The residual alkaline solution is then treated with sufficient dilute sulphuric acid to redissolve the precipitated base, and the alkaloid finally obtained in the free state by pouring the acid solution into ammonium hydrate. The precipitate is collected, washed and dried at 100° C. To prepare the quinethyline, the euphene is treated with ethyl chloride or bromide at 120—130° C., or preferably with ethyl nitrate. One molecule of euphene dissolved in alcohol, 1½ mols. of sodium, and 1½ mols. of ethyl nitrate are heated in a sealed tube to 95—100° C. for 12—15 hours. The alcohol is then distilled off, the residue taken up with acidulated water, and an excess of sodium hydrate added, which redissolves any euphene that

has been unacted upon. The new base is then extracted from the alkaline liquid with ether, the ether distilled off and the basic sulphate and then the neutral sulphate of quinethyline prepared, which latter is purified by repeated recrystallisation from hot water.

Quinethyline, $\text{C}_{15}\text{H}_{23}\text{N}_2\text{O}_2\cdot\text{OC}_2\text{H}_5$, is prepared by treating the neutral sulphate with a slight excess of ammonia in the cold. It is precipitated as a white amorphous powder closely resembling quinine. This precipitate is hydrated, and melts at 60° C., but by careful drying first in the air and finally at 125° C., it is obtained in a pulverulent form, when it melts at 160° C. It is very soluble in ether, alcohol, &c.; the sulphuric acid solution of the base is strongly fluorescent. Quinethyline could not be obtained in a crystalline condition, but it forms a crystalline hydrate; like both quinine and euphene it is levo-rotatory, $[\alpha]_D^{20} = -169.4^\circ$. The acid sulphate of the base, $(\text{C}_{15}\text{H}_{23}\text{N}_2\text{O}_2)_2\cdot\text{H}_2\text{SO}_4\cdot\text{H}_2\text{O}$, is only slightly soluble in cold water, whilst the neutral sulphate is considerably more soluble, and forms large prisms, which effloresce in the air and have the composition $\text{C}_{15}\text{H}_{23}\text{N}_2\text{O}_2\cdot\text{H}_2\text{SO}_4\cdot 8 \text{H}_2\text{O}$.—C. A. K.

The Volatility of Creosote: Pharmaceutical Preparations. A. Reismann. *Pharm. C. H. N. F.* 1891, **12**, 203.

OFFICIAL creosote, a mixture of gnaiecol and creosol, only commences to boil at 205°—220°, but is volatile even at ordinary temperatures; thus, a sample which was exposed on a watch-glass to the air inside the ease of a chemical balance for less than four weeks, lost 65.6 per cent. of its weight. Creosote pills coated with cocoa, under similar conditions, lost 22.4 per cent. of the creosote they contained; sugar-coated pills kept better, losing, during the same time, only 5.6 per cent. The author considers enclosure in gelatin capsules the best method of making up pharmaceutical preparations of creosote.—E. B.

Terpenes and Camphor. O. Wallach. *Ber.* **24**, 1525—1579.

IN the following paper the author gives a summary of the more recent literature on the subject of the terpenes; many of the original papers to which he refers have been previously abstracted. (Compare this Journal, 1888, 517, 586, 587; 1889, 635; 1890, 963, 964, 1147.)

The terpene-like hydrocarbons may be classed into three groups, according to their molecular formula:—(1.) Hemiterpenes or pentenenes, C_5H_8 . (2.) True terpenes, $\text{C}_{10}\text{H}_{16}$. (3.) Polyterpenes $(\text{C}_5\text{H}_8)_n$.

The true terpenes undergo decomposition at a moderately high temperature, being partially converted into unsaturated hydrocarbons of the valerylene series, the best known member of which is isoprene; isoprene, and the ordinary terpenes undergo polymerisation at a high temperature and are transformed into polyterpenes of the molecular formula $\text{C}_{15}\text{H}_{24}$, $\text{C}_{30}\text{H}_{48}$, &c.; of these polyterpenes, to which class belong, amongst others, caoutchouc and eolophony, the sesquiterpenes, $\text{C}_{15}\text{H}_{24}$, are most commonly found in ethereal oils.

At the present time there are nine terpenes which have been characterised with certainty as distinct substances, namely, pinene, camphene, fenchene, limonene, dipentene, sylvestrene, phellandrene, terpinene and terpinolene.

Pinene is the fundamental constituent of the ordinary varieties of oil of turpentine; it is the principal constituent of the ethereal oils of most pines, and also occurs in larger or smaller quantities in numerous ethereal oils from other sources.

Camphene is important on account of its close relationship with camphor (see below), but whether it occurs in nature has not yet been determined.

Fenchene has only recently been discovered; it is very closely related to camphene, as will be shown later on.

Limonene is one of the most commonly occurring terpenes; it is present in the ethereal oil of the aurantiaceae, in the largest quantity in oil of Orange-peel, and also in oil of Lemon and oil of Bergamot; it is also found in con-

siderable quantities in Cumin oil, Dill oil, and oil of Fleabane, and is a never-failing constituent of oil of Pine-needles (this Journal, 1888, 587).

Dipentene occurs in oil of elemi (this Journal, 1889, 635), oil of Camphor, and in Russian and Swedish oil of turpentine; it is formed in particularly large quantities, together with isoprene, by the dry distillation of caoutchouc, and can also be obtained from certain terpene derivatives containing oxygen, for example, from cineol, terpin hydrate, and terpinol.

Sylvestrene has only hitherto been found, together with pinene, in Swedish and Russian oil of turpentine; the American oil of turpentine contains pinene but not sylvestrene, although it is obtained from the same species of pine.

Phellandrene, until lately, had been found only in the oils of Bitter-fennel and Water-fennel, but it seems to be somewhat widely diffused, and is now known to occur in oil of elemi, eucalyptus oil, &c. (this Journal, 1888, 587.)

Terpinene occurs in nature in oil of cardamom, and can be obtained artificially from other terpenes.

Terpinolene has been obtained artificially by various reactions, but has not yet been much investigated.

The terpenes exist in physically different modifications: Pinene, from American oil of turpentine, for example, is dextro-rotatory, whilst that obtained from the French oil (formerly called terbenzene) is levo-rotatory. Limonene, from the oil of the *Aurantaceæ* and from oil of Cumin, is dextro-rotatory, that from Pine-needle oil is levo-rotatory. Phellandrene, from oil of Fennel and from oil of Elemi, is dextro-rotatory, but that obtained from eucalyptus oil is levo-rotatory.

Most active terpenes can be converted into inactive modifications by heat and by various chemical agents, such as mineral acids; the inactive products are also formed by mixing equal quantities of the two active modifications of opposite rotatory power. The active terpenes give, as a rule, active derivatives; occasionally, however, the derivative has a rotatory power of opposite sign to that of the compound from which it has been obtained.

In some cases the inactive form of the terpene, or its derivative, is identical with the corresponding active modification in all respects except as regards optical properties; this is so with pinene, camphene, and phellandrene. Inactive limonene is, however, totally different from the active terpene in its whole behaviour; the derivatives of the two modifications have also so little resemblance that inactive limonene was formerly thought to be a distinct hydrocarbon, and named dipentene; it will be found convenient to retain this name for inactive limonene.

Although most active terpenes can be readily rendered inactive, some, such as dextro-rotatory sylvestrene (and the levo-rotatory sesquiterpene) cannot be converted into inactive modifications; others, such as fenchene, terpinene, and terpinolene are at present only known in the inactive forms.

As regards other physical properties it may be stated that pinene, camphene (melting point 50°), and fenchene boil at about 160° and have a specific gravity of about 0.86; limonene, dipentene, and sylvestrene boil at about 175° and have a specific gravity of 0.846 at 20° (see table, p. 852).

That the terpenes are unsaturated compounds is clearly shown by various reactions. They combine directly with the halogen acids yielding hydrochlorides and hydrobromides, but they do not all behave in the same way, as is shown by the following examples:—When perfectly dry hydrogen chloride is passed into dry pinene, a saturated crystalline compound $C_{10}H_{16}.HCl$ ("artificial camphor") is formed; camphene also combines with one molecule of hydrogen chloride under similar conditions, and the product is a saturated compound. Limonene shows a totally different behaviour; when it is treated with hydrogen chloride in absence of water it combines with one molecule of the acid yielding an unsaturated, optically active liquid having the composition $C_{10}H_{16}.HCl$; this compound combines with a second molecule of hydrogen chloride in presence of moisture, being converted into an inactive compound (dipentene dihydrochloride) of the composition $C_{10}H_{16}.2HCl$. Dipentene and sylvestrene resemble

limonene in their behaviour with hydrogen chloride. The melting points of the mono- and dihydrochlorides of the terpenes are given in the table (see page 852). From both these classes of compounds the terpenes can be regenerated by heating with aniline or sodium acetate.

The terpenes also behave differently towards bromine:—Some, as for example pinene and fenchene, combine with only one molecule of bromine-yielding saturated compounds, whilst others, such as limonene, dipentene, sylvestrene and terpinolene combine directly with two molecules of the halogen. Most of these compounds are crystalline (see table, p. 852) and like the hydrochlorides and hydrobromides are of great service in identifying the terpenes.

Some of the best defined terpene derivatives are those obtained by treating the terpenes with oxides of nitrogen or with nitrosyl chloride. Phellandrene, for example, can be readily detected by pouring a mixture of the sample and light petroleum on an aqueous solution of sodium nitrite, and then gradually adding acetic acid, with frequent shaking; if phellandrene is present a voluminous, unstable, crystalline compound of the composition, $C_{10}H_{16}.N_2O_3$, is quickly deposited. Terpinene also combines with nitrous acid, but much more slowly, yielding a very stable nitrosite, $C_{10}H_{16}.N_2O_3$, which crystallises in prisms and melts at 155° .

The other terpenes do not yield crystalline derivatives with oxides of nitrogen, but combine with nitrosyl chloride forming nitrosochlorides of the general formula—

These compounds can be easily prepared by treating a solution of the terpene in glacial acetic acid, or alcohol, with amyl or ethyl nitrite, and then adding hydrochloric acid to the well-cooled mixture (this Journal, 1888, 517). If in the above reaction nitric acid is used in the place of hydrochloric acid, nitrosates of the general formula—

are produced (this Journal, 1888, 517); the nitrosates are sometimes very serviceable for the isolation of particular compounds, but they are frequently more soluble than the nitrosochlorides or else do not crystallise.

The unsaturated terpene hydrochlorides, such as limonene and dipentene hydrochloride, also yield crystalline, very sparingly soluble nitrosochlorides and nitrosates.

The nitrolamines (this Journal, 1888, 517) have also proved of great value for the identification of the terpenes. These compounds are easily obtained by treating the nitrosochlorides, nitrosates, nitrosites, or hydrochloronitrosates of the terpenes with organic bases such as piperidine, benzylamine, &c.; they crystallise very readily, are very stable, and have well-defined melting points (see table, p. 852).

When the nitrosochlorides are treated with reagents which eliminate hydrogen chloride, they are converted into nitroso-compounds of the general formula $C_{10}H_{15}NO$; in the case of pinene, limonene, and dipentene, these nitroso-derivatives crystallise well.

The author then proceeds to explain, with the aid of the following diagram and table (p. 852), some of the most important reactions of pinene. He considers that the behaviour of this terpene is best explained by assigning to it the constitution represented by the formula given below, and by assuming that in some reactions the para-binding is broken, and a second ethylenic binding formed between two other carbon atoms by intramolecular change.

As examples of some of the reactions of pinene, it may be mentioned that it is converted into dipentene by heating it at a high temperature; when treated with moist hydrogen chloride it is converted into dipentene dihydrochloride, $C_{10}H_{16} \cdot 2HCl$, but with dilute nitric acid it gives terpin ($C_{10}H_{16} \cdot 2H_2O$). Dipentene and its derivatives are not the only products of the action of moist acids on pinene; the formation of terpinene, terpinolene, terpineol, and cineol has also been observed, but these compounds are doubtless formed from terpin by secondary reactions. Pinene nitrosochloride is readily converted into crystalline nitrolamines by compounds such as pipridine and benzylamine, which have the nature of fatty bases; when, on the other hand, it is treated with true amido-compounds it is reconverted into pinene. By means of the last reaction it is possible to prepare chemically pure, inactive pinene (this Journal, 1890, 964). When pinene nitrosochloride is treated with alcoholic potash it loses one molecule of hydrogen chloride, and is converted into nitrosopinene, which, on reduction with zinc-dust and acetic acid, is transformed into pinylamine. Pinyl-

amine hydrochloride, when heated above its melting point, gives parisorpropylmethylbenzene (cymene).

The two terpenes, camphene and fenchene, are probably very similarly constituted. The former can be obtained artificially from camphor, and has probably the constitution given above; the latter is formed in exactly the same manner from fenchon, a substance isomeric with camphor, and which has recently been isolated from Fennel oil (this Journal, 1890, 1147). The close relationship between camphor and fenchon is clearly shown by the remarkable similarity in the chemical behaviour of the two compounds. As will be seen from an examination of the following table, (p. 853), the two substances form strictly analogous derivatives.

The constitution of limonene and dipentene is then discussed, and it is shown that the two compounds are structurally identical, dipentene being produced when equal quantities of dextro- and levo-rotatory limonene are mixed. Although this is the case, the physical properties of the derivatives of the two substances differ very considerably.

C ₉ H ₁₅ .COOH	Boiling point = 257°—260°	254°—255°
C ₉ H ₁₆	130°—140°

The two series of compounds also differ in solubility and in the facility with which they crystallise. Dipentene dihydrochloride, C₁₀H₁₈Cl₂, and the dihydrobromide, C₁₀H₁₈Br₂, can be converted into crystalline halogen substitution products; the hydrochloride yields the compounds C₁₀H₁₇Cl₃ (melting point 85°—86°) and C₁₀H₁₆Cl₂ (melting point 105°), and the hydrobromide gives a tribromide C₁₀H₁₇Br₃ (melting point 110°). When this tribromide is boiled with alcoholic potash it is converted into an unsaturated hydrocarbon (boiling point 182°) which is isomeric with eymene, and which forms a crystalline tetrahydride, C₁₀H₁₁Br₄, melting at 154°. A satisfactory constitutional formula for limonene cannot yet be put forward.

A substance closely related to dipentene is *Cineol* (eucalyptol, cajuputol), C₁₀H₁₈O (this Journal, 1888, 586), a compound which forms the principal constituent of the oils of Cina, Eucalyptus globul, and Cajuput, and which also

occurs in the oils of Rosemary, Laurel, Sage, Spike, Myrtle, Camphor, Lavender, and Australian eucalyptus. Cineol has the same boiling point as limonene, dipentene, and sylvestrene, but a much higher specific gravity and refractive power; when limonene or pinene contains a small quantity of cineol its properties are altered to such an extent that it may be easily mistaken for a distinct compound. It is, however, very easy to identify cineol owing to the readiness with which it combines with bromine and with hydrogen bromide. Cineol can be readily converted into dipentene by the action of dehydrating agents, and it is transformed quantitatively into dipentene derivatives in various reactions.

As regards the constitution of sylvestrene, terpinolene, terpinene, and phellandrene, nothing definite is known.

PATENTS.

A Manufacture of Iso-Eugenol and of certain of its Derivatives and their Application to the Manufacture of Vanillin. G. de Laire, Paris, France. Eng. Pat. 17,547, November 1, 1890. 6d.

ISO-EUGENOL, which has the formula—

is prepared from eugenol, or the Essence of Cloves, by heating it with caustic potash in amyl alcohol solution for 16–24 hours. After distilling off the amyl alcohol with steam, the residual liquid is treated with dilute sulphuric or hydrochloric acid, when the iso-eugenol separates and is decanted, washed, and purified by distillation: it boils at 258–262°C. By replacing the hydrogen of the hydroxyl group in iso-eugenol by an acid radicle, acetyl, propionyl, butyryl, valeryl, and benzoyl derivatives may be obtained, all of which yield vanillin on oxidation. In the preparation of these compounds, both mono-molecular and polymerised bodies may result: the latter only give small yields of vanillin when oxidised, and therefore the conditions favourable to the preparation of the former must be maintained. These conditions consist in heating the iso-eugenol with anhydrous acids, or in treating slightly alkaline solutions of the alkali salts of iso-eugenol with the acid chlorides.

Details for the preparation of the acetyl and benzoyl compounds are given: they are crystalline bodies, the former melting at 79–80°C., the latter at 103–104°C.

Improvements in the Manufacture of Methyl and Ethyl Phenacetine. B. Wilcox, London. From the "Fabriken vormals F. Bayer and Co.," Elberfeld, Germany. Eng. Pat. 18,022, November 8, 1890. 4d.

THIS is an improvement on the patent previously taken out for the preparation of methyl and ethyl phenacetine (Eng. Pat. 5723 of 1890; this Journal, 1891, 384).

To prepare the ethyl compound, phenacetine is first converted into the acetyl compound by treating it at the ordinary temperature with acetic anhydride in molecular proportions, the temperature being gradually raised to 100°C. during the addition. The whole is allowed to cool, alcohol added, and then distilled, when any excess of acetic anhydride is removed as acetic ether. The residue is distilled in vacuum, when it comes over as a clear liquid, which solidifies on standing, and consists of pure ethyl phenacetine. The methyl compound is prepared similarly. The acetic anhydride may be replaced by acetyl chloride, or less advantageously by acetic acid.—C. A. K.

Process for the Production of Anthranilic Acid. O. Imray, London. From "Amsterdamsche Chininefabrik," Amsterdam, Holland. Eng. Pat. 18,216, November 12, 1890. 6d.

See under IV., page 831.

A New Process for Producing Oxygen Gas. F. Fanta, London. Eng. Pat. 3034, February 13, 1891. (Under Internat. Conv., October 22, 1890.) 6d.

THE process is based on that of Tessier du Motay, in which manganates of soda are treated in a current of steam, when oxygen is evolved and the manganates reduced to sesquioxides of manganese, which are re-oxidised by heating in a current of air. Two special precautions are taken in order to obviate the melting and caking together of the material in the retort. In the first place, the manganate of sodium or potassium is prepared in a porous condition; full details for producing it in this form are given. And secondly, the air and steam employed in the operation are heated in the same furnace as the retorts or tubes in which the material

is placed previously to their entering the tubes, by which means any deposition of moisture which would render the material soft and liable to cake is obviated. The apparatus consists of a furnace in which a heating appliance for the air, a superheater for the steam and two independent series of tubes or retorts for the manganate, are fixed. In one of these series the manganate is treated with the superheated steam, and in the other the reduced manganate is re-oxidised by the hot air, this order of things being reversed at the end of each operation. Without any change of temperature, therefore, a continuous supply of oxygen is drawn off, which, after passing through a cooling apparatus and a washer, is collected in a gas-holder. The process may be repeated indefinitely. The superheating of the steam has the additional advantage of facilitating the reduction of the manganate, owing to the decomposition of the steam into hydrogen and oxygen that takes place. No details of plant are given.—C. A. K.

XXI.—PHOTOGRAPHIC MATERIALS AND PROCESSES.

Action of Sulphuric Acid on Quinol (Hydroquinone) and Effect of the Resulting Quinol Monosulphonic Acid on Gelatine-Bromide Plates. J. H. Stebbins, jun. J. Amer. Chem. Soc. 1891, 13, 155–159.

WHEN quinol (hydroquinone) is heated at 100° with twice its weight of sulphuric acid of 66°, it is converted into a mass of yellowish acicular crystals of quinol monosulphonic acid, $\text{C}_6\text{H}_4(\text{OH})_2\text{SO}_3\text{H}$, which can be freed from excess of acid by draining, and crystallised directly from alcohol. It can also be obtained in the usual way by decomposition of the barium salt. From alcohol it crystallises in brownish transparent rhombic prisms of the composition—

They lose the greater part of their alcohol over sulphuric acid at the ordinary temperature and the remainder at 120°. The barium salt crystallises with 1 mol. H_2O in concretionary stellate groups of acicular crystals. The potassium salt is obtained from the barium salt by double decomposition; it crystallises in small yellowish-white needles when the concentrated solution is mixed with three or four times its volume of alcohol and allowed to evaporate in a vacuum.

A solution of the barium salt made slightly alkaline with sodium carbonate, slowly develops a reddish-brown image on an exposed gelatine-bromide plate.—C. H. H.

Improvements in the Manufacture of Explosives. H. H. Lake, London. From S. T. G. Thorn, G. R. O. Westendarp, and G. L. C. Pieper, Hamburg, Germany. Eng. Pat. 16,189, October 11, 1890. 6d.

ABOUT 48 parts of trinitroresol are mixed with 20 parts of barium or strontium carbonate or hydrate, 33 parts of barium nitrate and all worked up together with a solution of soft resin, wax, &c., in alcohol into a dough-like mass, which is then dried and granulated.—W. M.

Improvements in the Manufacture of Lucifer and other Matches made of Wood, Cotton, or other Combustible or suitable Material. J. B. Searlett, Newhaven. Eng. Pat. 9196, June 1, 1891. 4d.

THIS invention consists in tipping both ends of each match with an igniting compound.—W. M.

Improvements in the Manufacture of Gunpowder. C. H. Curtis, London, and G. G. André, Dorking. Eng. Pat. 11,383, July 4, 1891. 4d.

THE inventors produce a smokeless powder by incorporating a mixture of soluble and insoluble nitrocellulose with nitroglycerin, preferably in the cold, the most suitable proportions being 40–47 parts of insoluble nitrocellulose, 20–23 parts of soluble nitrocellulose, and 30–40 parts of nitroglycerin, together with about 50–60 parts of acetone or acetic ether as a solvent.—W. M.

which must screw on with the fingers, and which should not be steam-tight. Any convenient support may be used for the oven. The breaking of a tube is evidenced by the gases escaping with a hissing noise from the leaky cap.

—T. L. B.

Conversion of Cartier and Baumé Degrees. J. A. Mandel and A. Bourgougnon. J. Amer. Chem. Soc. **13**, 169–170.

TAKING the specific gravity of the salt solution used for graduating Baumé's instrument as 1.073 (*Cherallier, Art de l'Ingénieur, &c., Paris, 1819*), and adopting the same notation as in a former paper (*Proc. Amer. Chem. Soc.* **1**, 53)—

$$\frac{V}{v} = \frac{1.073}{1} \text{ and } \frac{v}{v+10} = 1.073$$

whence $v = 136.9$.

Gay Lussac observed that 30° Cartier corresponds to 32° B., and 28° Cartier corresponds to sp. gr. 0.8791.

$$1^\circ \text{ Cartier} = \frac{32}{30} = 1.066 \text{ B.}$$

$$28^\circ \text{ Cartier} \times 1.066 = 29.848 \text{ B.}$$

$$144.329$$

$$134.329 + 29.848 = 0.8791$$

and, further, absolute alcohol at 15° has a sp. gr. = 0.795 and gives 41° Cartier.

$$44 \times 1.066 = 46.904 \text{ B.}$$

The tables give 47° B. = 0.795 sp. gr.—C. H. B.

XXIII.—ANALYTICAL CHEMISTRY.

APPARATUS.

An Apparatus for Heating Sealed Tubes. D. Woodman. J. Amer. Chem. Soc. 1891, **13**, 182–184.

THE apparatus, which is cheap, light, and convenient of use, and which is represented in the accompanying figure, is thus described:—

AN APPARATUS FOR HEATING SEALED TUBES.

A length of 5-inch stove-pipe, A B, is provided with sheet iron caps, C C, so made as to be easily removable. Into A B is fixed, by means of four rivets, a piece of sheet-iron of the same length as the oven, and bent down at the edges (*f f* represents a section of this); two holes are bored at suitable places in the top of the oven for thermometers, *t t*, and three half-inch holes, *h h h*, for direct admission of heat, Bunsen burners being placed directly underneath them. The thermometers should not, however, be placed directly over the burners as wrongly indicated in the figure. A piece of heavy asbestos paper is fastened round the oven by means of copper wire, and discs of asbestos are fitted into the caps C C. The tubes are heated on the shelf in wrought-iron tubes S, of 1-inch internal diameter; these tubes are fitted with screw caps,

INORGANIC CHEMISTRY.— QUALITATIVE.

On the Influence of Ammonium Hydrate on Arsenic Pentasulphide. Le Roy W. McCay. Chem. Zeit. 1891, **15**, 476.

AMMONIUM hydrate completely dissolves freshly-prepared arsenic pentasulphide precipitated from sulpharsenates of alkalis by hydrochloric acid, and well washed with water and absolute alcohol. The same is the case with arsenic pentasulphide freshly prepared by treating an acidified solution of arsenates of alkalis under pressure with sulphuretted hydrogen, and afterwards washing well with water and absolute alcohol. The solution appears first yellow and then almost colourless. No sulphur is precipitated, and the solution does not contain any arsenates. This solution contains sulphoxyarsenic acid after it has been treated in the following way:—First, highly diluted and cooled with ice, then acidified by a mineral acid, shaken and filtered, and the filtrate finally subjected to a current of air driven through it until the sulphuretted hydrogen is entirely expelled.

The author thinks it possible that the reaction is indicated by one of the following formulæ:—

INORGANIC CHEMISTRY— QUANTITATIVE.

The Estimation of Small Quantities of Alkali; and the Recognition of the Neutrality of Water. F. Mylius and F. Foerster. *Ber.* 1901, **24**, 1442—1448

Is the course of a research on the solvent action of water on glass, the authors endeavoured to directly estimate the dissolved alkali by means of a very weak solution of acid. An indicator suitable for the purpose was found in the shape of isolo-cosin or erythrosin ($C_{12}H_8O_5$), which, when used in the manner to be described is of extraordinary sensitiveness. Commercial Erythrosin requires to be purified for analytical purposes, and this may be done in the following way. A solution in aqueous ether is shaken out with a weak solution of caustic soda. A stronger solution of caustic soda is then added, by which means the brick-red sodium salt of Erythrosin is precipitated. The precipitate is washed with spirit and recrystallised from hot alcohol. From an aqueous solution of the purified salt, the Erythrosin is precipitated by the addition of hydrochloric acid, and thoroughly washed with water. For the estimation of traces of alkali, a milli-normal solution of acid is required. It must be prepared with absolutely pure water, and may be preserved unchanged for some time in a bottle of good glass. Titration is conducted as follows:—50—100 cc. of the water to be tested are placed in a stoppered bottle, and 10—20 cc. of an ethereal solution of erythrosin, containing not more than 2 mgrms. of the indicator per litre are added, and the whole is well shaken. If alkali be present the aqueous layer will assume a pink tint. Milli-normal acid is then added, the mixture being well agitated after each addition, until the pink colour disappears. Finally, milli-normal soda is run in until the colour just reappears. The amount required to do this (about 0.2 cc.) is subtracted from the volume of acid used. The method is capable of the most varied application. For instance, the carbonates in water may be estimated by its means (CO_2 does not sensibly affect the indicator). The decomposition of ammonium sulphate in boiling aqueous solution may be distinctly traced; and the presence of a minute excess of base or acid in salts of the alkalis, and of zinc, magnesium, cadmium, manganese, nickel and cobalt may be readily detected. The salts of iron (terrie) chromium and aluminium have an acid reaction. Silver and lead yield coloured salts with erythrosin, but as they are insoluble the process cannot be here applied. For the estimation of organic acids the method is altogether unsuitable.

For determining very small quantities of alkali (below 0.1 mgrm. Na_2O per 100 cc.) the process is preferably used colorimetrically. When a very dilute alkaline solution is shaken with an excess of ethereal erythrosin solution, the water is coloured more or less pink, according to the amount of alkali present. The intensity of the colouration is not proportionate to the amount of alkali, because, firstly, the water takes up a little free erythrosin from the ether; and, secondly, the alkaline erythrosate formed, is decomposed in very dilute solution into alkali and erythrosin.

The reagents required are

1. *Pure Neutral Ether.* Ordinary ether is shaken with soda solution, then washed once with water, and preserved in contact with water.

2. *An Ethereal Solution of Erythrosin.*—0.1 grm. is dissolved in one litre of aqueous ether (neutral).

3. *A Solution of Sodium Erythrosate.*—0.01 grm. of erythrosin is dissolved by the aid of 0.4 cc. of deci-normal soda and diluted to one litre with pure water.

4. *Neutral Water.* This the authors prepared by re-distilling distilled water, acidified with sulphuric acid, in an apparatus completely made of platinum. The authors define such water as neutral, 100 cc. of which take up from an ethereal solution of erythrosin a quantity of that substance equal in colour to 5.65 cc. of the standard solution of sodium erythrosate, diluted to 100 cc. In practice, ordinary distilled water may be neutralised with sulphuric acid, until its "erythrosin equivalent" is 5.6—5.7 cc. The following is the method of working:—100 cc.

of the liquid to be examined are placed in a cylindrical separator, 20 cc. of the ethereal erythrosin solution are added, and the whole is well shaken. The red aqueous layer, which will measure 110 cc., owing to absorption of ether, is transferred to a second separator and shaken with 10 cc. of aqueous ether to remove the excess of free erythrosin. Finally, the colour of the liquid is determined by comparison with water containing a known volume of the standard sodium erythrosate solution, 5—20 cc. of the latter diluted to 100 cc. being a suitable quantity. Experiments were made to determine the exact relation existing between the amount of alkali present and the colour intensity produced. The results are given in the table below:—

Quantity of Soda (Na_2O) per 100 cc. in 1000 Mgrms.	Volume of Sodium Erythrosate required to match the Colour observed.	Corresponding Amount of Soda in 1000 Mgrms.
0	0	0
10	14.5	6.6
15	20.5	11.0
20	25	14.3
25	31	18.8
40	45	29.1
60	66	44.7
80	86	59.5
100	104	72.8

The numbers in the last column are calculated on the assumption that the colourations observed are due to neutral sodium erythrosate, and that therefore 1 cc. of standard solution corresponds to 0.00074 mgrm. Na_2O . Allowance is of course made for the "erythrosin equivalent." It will be seen that the quantities of soda found average 72.1 per cent. of the amounts actually present. Taking this number, it appears that 1 cc. of erythrosate solution corresponds in reality to—

Mgrm.	
0.00102.....	Na_2O
0.00151.....	K_2O
0.00050.....	NH_3
0.00002.....	CaO

Employing these values the following results were obtained:—

K_2O	
Taken.	Found.
15.16	11.2
30.32	32.1
60.64	58.9
90.96	88.3
151.6	160.1
NH_3	
10.96	11.4
21.92	20.4
54.84	55.4

The above numbers represent $\frac{100}{1000}$ mgrms. per 100 cc. Carbonic acid somewhat affects the accuracy of the method, but unless present in large excess, the error introduced is not serious.—H. T. P.

Separation and Estimation of Antimony. J. Thiele.
Annalen, 1891, **263**, 361—376.

THE method devised by Tookey (Chem. Soc. J. **15**, 462) for the separation of antimony and tin, has been more exactly studied, and to some extent modified by Attfield and Clasen, without these chemists observing that oxidation of the metallic antimony precipitate takes place during the washing of the same, and that in consequence some of the antimony finds its way into the filtrate. The author has, therefore, considered it desirable to again test the accuracy of the method. Pure antimony trioxide, dried by heating in a current of carbon dioxide, was dissolved in hydrochloric acid and precipitated by electrolytic iron, as recommended by Clasen (J. prakt. Chem. **92**, 477). Previously to washing the precipitate on the filter, antimony could not be detected in the filtrate, but on commencing the washing (with pure boiled water) antimony made its appearance therein. Moreover, when the precipitate was washed for a long time with very dilute hydrochloric acid, its weight continuously increased. It thus appears that part of the antimony oxide formed remains on the filter, and that part passes into the filtrate. The following amounts of antimony precipitate were obtained from the weights of antimony oxide stated:—

No. of Experiment.	Wt. of Sb ₂ O ₃ taken. } = Sb.		Sb. found.	Error.	
	Grms.	Grms.		Grms.	Per Cent.
1	0.3742	0.3118	0.3112	0.0006	0.19
2	0.3267	0.2722	0.2720	0.0002	0.07
3	0.3106	0.2588	0.2591	0.0003	0.12

The percentages of oxygen contained in these precipitates were determined by carefully heating the same in weighed pieces of combustion tubing in a very slow current of hydrogen, the tubes being first heated beyond the precipitate in order to intercept any oxide which volatilised, mirrors of antimony being deposited on the red-hot glass. The following percentages were thus found: in precipitate (1) 2.31; in (2) 2.02; in (3) 2.28.

The antimony in the filtrates was estimated as pentasulphide by Bunsen's method, the following being the results:—

No. of Experiment.	Sb ₂ S ₅ Found = Sb.		Per Cent.
	Grms.	Grms.	
1	0.0077	0.0016	1.48
2	0.0081	0.0019	1.79
3	0.0089	0.0053	2.05

making the total percentages of antimony found—

—	1.	2.	3.
In the precipitate	97.40	97.96	97.84
In the filtrate	1.48	1.79	2.05
Total	98.88	99.75	99.89

The cause of the lowness of the above results was traced to the presence of antimony trisulphide in the precipitate obtained by Bunsen's method, the precipitate containing, on an average, 63 per cent. of metal, instead of 60 per cent., as it should do, did it consist entirely of pentasulphide.

In effecting the separation of antimony and tin, the author found unexpected difficulties: electrolytic iron precipitates tin as well as antimony; after heating in hydrogen, electrolytic iron dissolves very slowly in hydrochloric acid, leaving a residue of carbon (the iron was precipitated from a solution containing acetic acid), and

still precipitates a trace of tin. This trace was detected by dissolving the precipitate in hydrochloric acid by the aid of potassium chlorate, expelling the excess of chlorine by boiling, precipitating the antimony with iron, and testing the filtrate with mercuric chloride. Pure iron wire possesses the advantages over heated electrolytic iron of dissolving readily and completely, but like the latter precipitates a little tin.

The only method which enabled the author to obtain a filtrate free from antimony, consisted in precipitating the antimony with a large excess of heated electrolytic iron, at once transferring the precipitate to a filter and washing in an atmosphere of hydrogen. This method, however, possesses the disadvantage of entailing a separation of the antimony from the undissolved iron, which is effected by dissolving the antimony in a concentrated solution of sulphur in potassium hydrate, filtering, treating the solution with chlorine, and estimating the antimony by Bunsen's method. It is necessary to use a concentrated solution of potassium sulphide, as otherwise finely-divided ferrous sulphide passes through the asbestos filter and vitiates the results.—E. B.

The Estimation of Silica in Presence of Iron. Leclere.
Compt. Rend. 1891, **112**, 1132—1133.

OWING to the difficulty, in the presence of much ferric chloride, of evaporating the residue of a solution to dryness for the purpose of rendering the silica insoluble, the author takes advantage of the fact that the double chloride of iron and potassium dries readily. The method which he recommends is as follows:—For the determination of the silica in cast iron, 1 gram. of the metal is dissolved by the aid of 20 cc. of nitric acid and 10 cc. of hydrochloric acid; the greater part of the acid is boiled off, two quantities of 30 cc. of hydrochloric acid are added to expel the nitric acid, and finally 3 grms. of ammonium chloride are added and the residue heated gently to expel the last traces of nitric acid. The residue is dissolved in hydrochloric acid, and then 3 grms. of potassium chloride are added and the evaporation carried to dryness. These salts are soluble in cold water, but a little hydrochloric acid is added in order to bring other bases which may be present into solution. The silica remains insoluble with the carbon. They are filtered off, and after ignition the silica may be weighed. The presence of ammonium chloride prevents the silica from carrying down manganese. When chromium is present this is best reduced by means of a little zinc. The results obtained are satisfactory.—J. W. L.

ORGANIC CHEMISTRY.—QUALITATIVE.

The Use of Ammonium Selenite as a Test for the Alkaloids.
A. J. Ferreira da Silva. Compt. Rend. 1891, **112**, 1266—1268.

LAFON has employed ammonium selenite as a test for morphine and for codeine; the reagent consists of a solution of 1 gram. of the salt in 20 cc. of concentrated sulphuric acid, and gives a green colouration with the above two alkaloids. The author has examined the action of this reagent with other alkaloids with the following results:—Aconitine, no immediate colouration, slight rose colour after 20 minutes. Berberine, yellow to brown and finely wine-red colouration. Brucine, rose to pale orange, and then amber colouration. Caffeine and cocaine, slight rose colouration on standing. Curarine, slight violet to red colouration. Delphine, slight violet colouration, turning red on standing. Digitaline, no immediate colouration, then yellowish and reddish precipitate on standing. Escerine, yellow to orange colouration. Morphine, greenish-blue colouration, which turns chestnut brown on standing; no precipitation. Narcotine, blue colouration, turning first violet and then reddish; slight precipitate of a reddish colour after three hours standing. Narceine, yellowish-green colouration turning to brown and then to red; red precipitate on standing. Papaverine, blue colouration passing to bottle-green, violet, and finally red; on standing a slight bluish precipitate is deposited. Solanine, yellow colouration passing to brown,

red, and finally violet. Saponine, yellow colouration turning red; a very delicate test. Senegine, pale yellow colouration, which becomes reddish on standing. Veratrine, yellowish colouration, which after standing three hours deposits a red precipitate, whilst the solution remains yellow. Cinchonine, cinchonidine, atropine, and pilocarpine do not give any reaction with ammonium selenite. The author is of opinion that these reactions are not entirely due to the reducing powers of the alkaloids, causing a separation of metallic selenium which dissolves in the sulphuric acid of the reagent, but that some special action takes place in the case of each of the alkaloids.—C. A. K.

ORGANIC CHEMISTRY—QUANTITATIVE.

The Estimation of Sugars with Copper Potassium Carbonate Solution. No. III. H. Ost. Ber. 1891, **24**, 1631—1636. (Compare this Journal, 1890, 1160.)

This communication deals with the estimation of maltose; the preparations employed were crystallised 3—5 times from dilute alcohol. After remaining for a week over concentrated sulphuric acid the compound is constant in weight, but does not lose its water of crystallisation, the latter being only slowly removed at 100—110°, and not without decomposition. Maltose exhibits a similar behaviour towards copper potassium carbonate solution as towards Fehling's solution, less copper being reduced than by the monosaccharides (monoses). The amount of reduction is less influenced by the presence of an excess of dissolved copper.

In carrying out the experiments 50 cc. of the copper solution were diluted to 75 cc. and gently boiled for 10 minutes with various weights of maltose hydrate, and the remainder of the operation conducted as previously described (Zeits. f. anal. Chem. 1890, 637; this Journal, *loc. cit.*). 50 cc. of the copper solution are exactly precipitated by 195 mgrms. of maltose hydrate. Single determinations are in better agreement than those formerly cited in the case of milk sugar, but are not so close as those obtained with dextrose and galactose (this Journal, *loc. cit.*). For example, 100 mgrms. of maltose hydrate gave on boiling as above described for 10 minutes, 165, 167, 169, 169, 167.7, 168, 169, and 165.4 mgrms. of copper; mean = 167.5 mgrms. of copper; on boiling for 15 minutes, 169.3 mgrms. of copper; and on boiling for 20 minutes, 173.2 mgrms. of copper. The conditions of the experiments were such that they can easily be attained by other chemists. The following table is constructed from the mean results obtained when the boiling was maintained for 10 minutes:—

Copper.	Maltose Hydrate, $C_{12}H_{22}O_{11} \cdot H_2O$.	Anhydrous Maltose.

—A. R. L.

The Rotatory Power of Levulose and Invert Sugar. H. Ost. Ber. 1891, **24**, 1636—1645.

The author undertook the experiments described below in view of the contradictory results of other chemists as to the rotatory power of levulose. The levulose employed was prepared from inulin, and after being crystallised three or four times from absolute alcohol, resembled to outward appearance that of Honig and Schubert (this Journal 1888, 445). It formed compact mammillated aggregates of prisms, and when dried over concentrated sulphuric acid was generally anhydrous; whilst Jungfleisch and Grimbirt's preparation (this Journal, 1888, 761) contained 2.5 per cent. of water. The author's preparation was not hygroscopic, and when heated in a stream of hydrogen at 100° in a Liebig's drying tube it melted and slowly lost weight (0.75 per cent. in 10 hours), without becoming constant. He cannot confirm Jungfleisch and Grimbirt's observation that a solution of levulose is decomposed when heated at 50°, or that the rotatory power is affected even when heated at 100°. To determine the specific rotatory power of levulose all the

weighings were reduced to a vacuum. The results obtained for solutions containing 3–30 per cent. by weight of levulose are represented by the formula—

$$[\alpha]_{D_{20}} = - (91.90 + 0.111 p)$$

where p is the weight in grms. of levulose in 100 grms. of the solution. Like those of dextrose, more dilute solutions of levulose have a much lower specific rotatory power. The values are plotted side by side with those of Hönig and Jessor (Zeits. f. Rübenzuck. Ind. 1888, 1027), and also with those of Jungfleisch and Grimbert. It is found that they are higher than the former for solutions containing less than 25 per cent. and lower for concentrations above this; whilst they are about 3 per cent. higher throughout than the latter; this may perhaps be due to the presence of an optically inactive impurity in the levulose employed by Jungfleisch and Grimbert. The specific rotatory power of a mixture of levulose and dextrose (equal parts) was next determined for different concentrations. The dextrose was carefully dried at 100°, crystallised from absolute methyl alcohol and dried over concentrated sulphuric acid. The results agree well with the calculated values, taking the author's numbers for levulose and those of Tollens (Ber. 17, 2234; this Journal 1885, 132); the agreement is however still better if 0.1–0.2 be deducted from Tollens' numbers, and the fact that Tollens dehydrated his dextrose by heating it at 60–70°, whereby it may have undergone slight change, appears to justify this deduction. The author has obtained the following results with his dextrose dried over concentrated sulphuric acid (see above); for $p = 10$, $[\alpha]_{D_{20}} = 51.54$ (52.74 Tollens); for $p = 2$, $[\alpha]_{D_{20}} = 52.15$. The mean of three determinations of the rotatory power of invert sugar produced by the Clerget-Herzfeld inversion method gave $[\alpha]_{D_{20}} = -20.71$ ($p = 13.035$), whereas the rotatory of pure invert sugar for the same concentration is $[\alpha]_{D_{20}} = -20.28$. 13 per cent. solutions of pure invert sugar and of levulose were treated at different temperatures and for various lengths of time with aqueous solutions of oxalic and acetic acids; the results are in agreement with those of Gubbe (Ber. 18, 2214; this Journal, 1885, 747) and show that a 0.1 per cent. solution of oxalic acid at 50°–53° has no influence on the specific rotatory power of invert sugar even after several hours; the specific rotatory power of levulose is however lowered from—

$$[\alpha]_{D_{20}} = -93.34 \text{ to } [\alpha]_{D_{20}} = -92.02 \text{ and } -92.19$$

on heating with a 0.25 per cent. solution of oxalic acid and a 0.25 per cent. solution of hydrochloric acid respectively for 15 minutes at 100°. Contrary to the statement of Jungfleisch and Grimbert, however, a 5 per cent. solution of acetic acid lowers the rotatory power of invert sugar, even at the ordinary temperature from—

$$[\alpha]_{D_{20}} = -20.3 \text{ to } [\alpha]_{D_{20}} = -19.77.$$

The inversion of cane sugar is best effected by heating it with a 2 per cent. solution of oxalic acid for 1.5 hours or with a 1 per cent. solution for 4 hours at 60°; this method gives a specific rotatory power $[\alpha]_{D_{20}} = -20.16$ ($p = 13$). A solution of invert sugar prepared according to Soxhlet's method by heating cane sugar with 0.1 per cent. hydrochloric acid is not quite identical with that obtained by the Clerget-Herzfeld method. The former has a specific rotatory power $[\alpha]_{D_{20}} = -19.25$ – -19.50 ,

whereas $-\frac{99.5 + 52.1}{2} = 19.2$, and as furthermore it has the same reducing power as a solution of a mixture of pure dextrose and levulose (equal parts), it is to be recommended for standardising the copper solution.

Note on Ost's Communication on "The Rotatory Power of Levulose and Invert Sugar." B. Tollens. Ber. 1891, 24, 2000.

THE author draws attention to his work in conjunction with Pareus (Annalen, 257, 165; this Journal, 1890, 748) in which similar views to those of Ost (preceding abstract) are expressed, viz. that the specific rotatory power of levulose is higher than it has hitherto been considered to be. In one experiment, for example, the value of $[\alpha]_{D_{20}} = -93.03$ was obtained for a 10 per cent. solution which agrees closely with that of Ost. Referring to the observations of the latter on the specific rotatory power of dextrose, Tollens does not consider it finally established that the differences between his results and Ost's are due to his own preparation having undergone slight decomposition on drying at 50°–60°, an alternative view being that Ost's preparation contained 0.2 per cent. of water.—A. R. L.

Action of Nitric Acid upon Plant Fibres. C. F. Cross and E. J. Bevan. Ber. 1891, 24, 1772–1776.

See under V., page 831.

On the Cryoscopic Behaviour of Aqueous Solutions of Cane Sugar. J. F. Eykman. Ber. 1891, 24, 1783–1785.

THE author has repeated Traube's experiments (this Journal, 1891, 660); his results, which are shown in the following table, contrary to those of Traube, are perfectly normal:—

Percentages of Cane Sugar.	Mgm. Mols. per Kilo.	Depression Observed.	Molecular Depression.
0.4473	13.08	0.026	19.9
0.8218	24.03	0.047	19.5
1.115	32.6	0.065	20.2
1.613	47.16	0.102	21.6
3.073	89.9	0.193	21.5
5.64	164.9	0.367	22.3
11.72	347.2	0.797	23.3

The Influence of Inactive Bodies on the Rotatory Power of Dilute Solutions of Dextrose. N. Wender. Ber. 1891, 24, 2200–2203.

IT is known that the inactive constituents of diabetic urine affect the rotatory power of fairly strong solutions of dextrose. Urea, and to some extent, ammonium salts, exert a depressing influence; and it is therefore quite possible that the dextro reading of any small amount of dextrose existing in normal urine might be completely masked and thus overlooked. To settle the point, solutions of dextrose were prepared, with and without the addition of urea, and the rotatory powers were carefully taken. The following results were obtained:—

Dextrose taken.	Urea Taken.	Solvent.	Length of Tube.	Temperature.	Rotatory Power Observed.	Difference.
Grms.	Grms.		Decim.	° C.	°	
0.3976	..	Water up to 100 cc.	2	22.5	+ 0.424	} — 0.003
0.3976	1.028		2	22.5	+ 0.421	
0.106	..		2	20.5	+ 0.103	} + 0.0075
0.106	2.030		2	20.5	+ 0.1105	
0.102	..		2	20.5	+ 0.2952	} + 0.0038
0.102	2.095		2	20.5	+ 0.2900	

Next, a sample of normal urine was decolourised by means of animal charcoal and used as solvent for the dextrose.

Length of tube = 2 decim. Temperature 20° C.

Dextrose taken.	Solvent.	Rotatory Power.	Difference.
Grms.	100 cc.		
0.1141	Water	+ 0.416	
0.1110	Urine	+ 0.108	- 0.008

It is evident, therefore, that the constituents of urine exert no influence whatever on the rotatory power of dilute dextrose solutions—H. T. P.

On Hubl's Method for the Examination of Wax. R. Benedikt and K. Mangold. Chem. Zeit. 1891, 15, 474—475.

This method, although of great value, has the drawback that certain kinds of wax are saponified by it only with difficulty when treated with alcoholic lye. For instance, if a wax contains ceresin, the saponification numbers obtained are nearly always too low. To avoid these inaccuracies the following modifications are recommended by the authors:—

1. The acid number is ascertained in the way indicated by Hubl, and it is advisable to use a considerable quantity of the substance (7 to 10 grms.) for the test.

2. Instead of the saponification number the "total acid number" is determined, by which is understood the quantity of caustic potash necessary for neutralising a mixture of fatty acids and fatty alcohols, obtained after previously decomposing the saponified wax by dilute hydrochloric acid. To obtain this mixture 20 grms. of caustic potash are dissolved in 15 cc. of water and boiled, to this during continuous stirring are added 20 grms. of the wax which has been melted on the water-bath. The mixture is heated and stirred for 10 minutes more, then diluted with 200 cc. of water; heated again and acidified with 10 cc. of hydrochloric acid slightly diluted with water. It is then boiled until the upper part appears clear, then allowed to stand, and the wax cake boiled, first with water containing some hydrochloric acid, and subsequently twice with water alone. Then the wax cake is dried with filter-paper, and melted in the drying oven and the liquid filtered. The filtrate solidifies as it cools. Six to 8 grms. of the substance thus obtained are treated with alcohol free from acids, heated on the water-bath, and titrated after phenolphthalein has been added. The total acid number thus obtained is somewhat lower than Hubl's saponification number. If s be the acid number, S the total acid number, and a the ether number, we have Hubl's saponification number $a + s$ and—

$$\begin{aligned} a &= 56100 (S - s) \\ &= 56100 - 18S \\ S &= 56100 (a + s) \\ &= 56100 + 18a \end{aligned}$$

The total acid numbers of various kinds of yellow beeswax of different origin varied from 88 to 93; as an average figure 92.8 is given, corresponding to the saponification number 95. The amount of wax W contained in ceresin is then determined by the formula—

$$W = \frac{100S}{92.8}$$

or, more accurately—

$$W = \frac{97.72S}{92.75} = 0.0228S$$

If, however, small quantities (6 per cent. or less) are mixed with beeswax, this test is no longer applicable, and Buisine's method must be used instead. When stearic acid or resin is present, the acid number is higher; if σ be the average

acid number of such additions, these additions are calculated by the formula—

$$K = \frac{100(s - 20)}{\sigma - 20}$$

Stearic acid, as used for technical purposes, has $\sigma = 200$, hence we have in this case—

$$K = \frac{10(s - 20)}{18}$$

When fats or tallow are present, the following formula has to be used—

$$W = \frac{100(S_f - S)a}{(S_f - S)a + (S - S_{ic})b}$$

where S is the total acid number, S_{ic} the total acid number of pure beeswax, S_f that of fat, a the quantity of wax necessary for obtaining 1 gm. of substance as above described by the treatment with dilute hydrochloric acid, and b the quantity of fat which yields 1 gm. of insoluble fatty acids (see also this Journal, 1891, 52, 53, 728 and 729). —H. S.

Analysis of Beeswax. C. Mangold. Chem. Zeit. 1891, 15, 799—800.

An adulteration of beeswax with less than 6 per cent. of ceresin or paraffin cannot be detected with certainty by any of the ordinary methods because the relations between the free fatty acid and saponifiable and unsaponifiable matters in genuine beeswax vary within somewhat considerable limits. The detection of smaller quantities of these adulterants can only be made possible by a direct determination of the hydrocarbons present, and the author describes a modification of a method recently brought out by A. and P. Buisine (this Journal, 1891, 52 and 729) with that object. The method is based on the observation of Dumas and Stas that if a saponified wax be heated with potash lime, the fatty alcohols are decomposed with formation of fatty acids and evolution of hydrogen, the volume of which becomes a measure of the fatty alcohols present, whilst the hydrocarbons may be dissolved out of the residue and weighed. The recent improvements of the method consist in the simplification of the apparatus and a more exact knowledge of the conditions to be observed. From 2 to 10 grms. of the wax are saponified by melting with potash lime. The solid dry soap is then powdered and well mixed with three times its weight of potash lime, and placed in a strong pear-shaped flask, in which it is heated to 250° for two hours. The apparatus for conducting this operation is shown in the sketch. A is an iron vessel with a lid

APPARATUS FOR ANALYSIS OF BEESWAX.

fastened down by screws, and filled with mercury. The flask or eprouvette E is connected, gas-tight, with a Hofmann's burette H for measuring the hydrogen evolved. T is a thermometer and V a temperature regulator. K is a condensing tube for mercury vapour. The author recommends that the heating at 250° be continued for three hours to secure completion of the reaction, after which the flask is allowed to cool, and is broken up to liberate the residual mass, which is then powdered and extracted with petroleum spirit in a Soxhlet apparatus. The residue left on evaporation of the petroleum spirit is dried at 110° and weighed. Genuine beeswax examined by this method give always some hydrocarbons, but the experience of the author and other observers is to the effect that the quantity is almost invariably between 12.5 and 14.5 per cent. The mean of these quantities or 13.5 must therefore be deducted from the total hydrocarbon found, and the difference is the amount of hydrocarbon added by way of adulteration. The results of numerous analyses accompany the article.

New Reagent for Acetone. A. Schwicker. Chem. Zeit. 1891, 15, 914.

A MIXTURE of acetone and aqueous ammonia dissolves powdered iodine with evolution of heat, the liquid becomes turbid, and after a time a deposit of iodoform is formed; a penetrating smell which irritates the eyes and is probably due to some iodine substitution product of acetone, is simultaneously produced. This reaction may be used as a test for small quantities of acetone even in presence of alcohol, as the latter gives no reaction under the circumstances.

The test is best made as follows:—A few drops of strong ammonia are added to the solution containing acetone, then 1 or 2 drops of decinormal iodine, a darkish precipitate of iodide of nitrogen forms but disappears on shaking, or on gently warming, and when the solution of acetone is not too dilute it is immediately succeeded by a yellowish turbidity due to the formation of iodoform. Successive additions of 1 or 2 drops of iodine solution are repeatedly made, allowing the liquid to stand a little while after each addition and then shaking it well. The smell of iodoform can be clearly distinguished in the liquid in spite of the presence of ammonia. Any accumulation of iodide of nitrogen formed after successive additions of iodine may be dissipated by adding 1 or 2 drops of a very dilute solution of sodium thiosulphate, but this reagent disturbs the reaction if added too soon.

Very dilute solutions of acetone should be treated with a more dilute solution of iodine and the precipitate of iodide of nitrogen, which in these cases forms at once, should be left to itself for a considerable time before warming or treating with sodium thiosulphate. The reactions which occur are probably represented by the equations—

The author believes that the iodoform reaction described would be given by all ketones containing the acetyl group. After prolonged standing aldehyde yields a similar precipitate of iodoform with ammonia and solution of iodine.

—S. B. A. A.

Analysis of Shoe Blacking. J. Pinette. Chem Zeit, 1891, 15, 917.

ABOUT 5 grms. of blacking are weighed out into a 200 cc. separating funnel, 100 cc. of water added, and the liquid is made up to the mark with a mixture of equal volumes of ether and light petroleum. The whole is then well shaken, allowed to subside, and the height of the layers read off. 25 cc. of the ethereal solution are pipetted off, filtered, evaporated to dryness, and the residual fat weighed. An aliquot part of the aqueous layer is filtered and titrated with decinormal soda and phenolphthalein for free acids, the

neutral solution obtained evaporated to dryness in an unweighed platinum dish, the dish and residue weighed, ignited and again weighed. The difference between the two last weighings gives the invert sugar and extractable matter.

Another aliquot part of the aqueous solution is neutralised with decinormal soda, evaporated until free from ether, filtered, made up to 25 cc., and the invert sugar determined with Fehling's solution. The extractable matter is found by difference. Water and ash are estimated in separate portions. The difference between the sum of the percentages thus obtained and one hundred is taken as carbon. The ash is analysed like other phosphatic mixtures. The free acid found is not sulphuric acid, as stated by Hölling, but, phosphoric acid, and exists either in the free state or in acid phosphates. Of late, varieties of blacking free from acids have come into the market, a highly bituminous schist being used in place of bone-black in their manufacture. These blackings are simply mixtures of fat, molasses, and black schist, with the occasional addition of an antiseptic. The following analyses are given of the two classes of blacking:—

	No. 1.	No. 2.
	Acid Blacking.	Blacking Free from Acid.
Water ..	23.84	13.28
Fat ..	5.53	3.48
Free acids ..	1.66	..
Invert sugar ..	20.14	..
Cane sugar	23.35
Extractive matter ..	3.40	10.81
Carbon ..	7.86	9.49
Combined water	
P ₂ O ₅ ..	10.24	..
SO ₃ ..	8.76	..
CaO ..	12.06	..
Na ₂ O ..	5.61	..
Ignited siliceous matter	39.59
	100.00	100.00

From this the proportions of the raw materials employed in the manufacture appear to be in round numbers as follows:—

	No. 1.	No. 2.
Bone black ..	13.0	..
Molasses ..	68.0	63.5
Sulphuric acid ..	12.0	..
Soda ..	4.5	..
Fat ..	2.5	2.5
Black schist (losing 20 per cent. on ignition)	31.0

—S. B. A. A.

Analysis of the Calcined Vinsasse from Beet Molasses.

C. Heyer. Chem. Zeit, 1891, 15, 915 and 959—960.

THE total potash in the ash of the vinsasse from beet molasses is generally determined by converting the potassium sulphate in an aqueous solution into chloride, by the addition of an equivalent quantity of barium chloride, filtering and evaporating an aliquot part of the filtrate with platinum tetrachloride. The percentage of potassium chloride is also estimated directly in the solution of the ash

by neutralising exactly with nitric acid, and titrating with a decinormal silver solution. The author has found that these methods yield inaccurate results in many cases, owing to the incomplete calcination of the vinasse and consequent presence in the ash of nitrogenous compounds which on heating with water are partially converted into ammonia, and estimated as potash. In one sample 1.53 per cent. of ammonia was found in solution after boiling with water for five hours and with potash for one hour, and the residues still contained 0.19 per cent. of nitrogen. It is, therefore, absolutely indispensable to recalcine the ash before estimation, and the percentage of potassium salts varies with the thoroughness of this calcination.

The following analyses of the same sample of ash show the extent of the variation—

	a.	a ¹ .	b.	A.	B.	C.	D.
K ₂ CO ₃	61.74	67.32	67.35	61.20	72.27	71.24	63.79
KCl.....	13.54	13.54	12.20	13.66	11.66	13.47	11.45
K ₂ SO ₄	1.91	1.61	1.76	1.81	0.79	0.60	1.05
K ₂ PO ₄	0.27	0.27	0.24	Trace	Trace	0.30	0.20
Na ₂ CO ₃	0.84	8.70	10.74	10.74	6.42	5.93	13.72

a was obtained by precipitating the aqueous solution of the ash with barium chloride, evaporating a portion of the filtrate almost to dryness and adding a solution of platinum tetrachloride; *a*¹ was obtained by evaporating a portion of a solution to complete dryness, drying at 120 and gently igniting before treatment with platinum chloride; *b* resulted from the drying and thorough calcination of a portion of the original solution of the ash, with subsequent re-solution, precipitation of the sulphuric acid, and addition of the platinum salt; A, B, C, and D are determinations made by other analysts.

Before titrating the chlorine, it is advisable to boil the acid solution in order to decompose the cyanides which remain in the ash even after thorough ignition. When the ash contains soluble sulphides or sulphocyanides, a little nitric acid or bromine water should be added to the calcined mass, and the solution after addition of barium chloride should be allowed to stand for about six hours.—S. B. A. A.

An Apparatus for Weighing Oil. R. Hefelmann. Chem. Zeit. 1891, 15, 989.

The pipette P fits air-tight into the small conical weighing beaker W. The pipette is graduated as shown and its

APPARATUS FOR WEIGHING OIL.

upper end is closed by the rubber ball H. By this apparatus the required quantity of oil for various determinations may be quickly weighed.—A. L. S.

The Determination of Acid Tartrate in Wine Lees.
B. Balli. Chem. Zeit. 1891, 15, 989—991.

P. PHILLIP and Co.'s method consists in neutralising the acid tartrate with soda or potash, filtering and precipitating the acid tartrate from the solution of the neutral tartrate by acetic acid.

Kammer neutralises in the cold instead of at the boiling temperature.

The author finds that this method is not applicable to the analysis of wine lees and other impure materials, which often contain calcium sulphate and carbonate and potassium carbonate.

On neutralisation calcium sulphate reacts with neutral potassium tartrate as follows:—

When calcium sulphate is present the result of the analysis will consequently be low.

Calcium carbonate reacts on the acid tartrate as follows:—

The analytical numbers will consequently in this case be also low.

The presence of potassium carbonate will, on the other hand, cause the analytical numbers to be high, as the presence of this salt is equivalent to the presence of neutral potassium tartrate which on the addition of acetic acid would yield its equivalent amount of acid tartrate, in addition to that produced from the acid tartrate available in the substance analysed.

The author recommends the following modification of the method.

The analysis is carried out in two parts.

The raw tartar is boiled with water, when the carbonates react on the acid tartrate as follows:—

On neutralisation the available acid tartrate is dissolved, and the clear solution thus contains neutral tartrate from the available acid tartrate and neutral tartrate as produced according to the first equation by the action of potassium carbonate, and neutral tartrate as produced according to the second equation by the action of calcium carbonate. The neutral tartrate in the solution is estimated by adding calcium chloride, acetic acid, and alcohol, the precipitate of calcium tartrate is filtered off and titrated with semi-normal alkali. The resultant figures are in excess of the amount of available acid tartrate as explained above, and a subsidiary analysis is necessary to determine the correction. This may be done in two ways:—

A. Indirect Method.—A portion of the crude tartar is boiled with water and the solution filtered; the solution is diluted and acidified with acetic acid and calcium chloride added. The precipitate is filtered off and titrated. The result gives the amount of bitartrate and neutral tartrate in the solution. The amount of bitartrate must be determined in another portion of the solution, in exactly the same way, only omitting the acidification. The difference between the two results gives the amount of neutral tartrate.

B. Direct Method.—The crude tartar is boiled with water and the solution is cooled and diluted. A part of the acid tartrate crystallises out and the mother-liquor is a saturated solution of acid tartrate containing all the neutral tartrate in solution. On adding acetic acid to this a quantity of acid tartrate is formed, equivalent to the neutral tartrate in solution, and as the solution is already saturated with the salt the whole thus formed crystallises out; it is filtered and washed with alcohol and weighed.—A. L. S.

Rapid Method of Estimation of Common Salt in Wine.
J. Gondoin. J. Pharm. Chim. 1891, 24, 8.

To 10 cc. of the wine under examination, 1 cc. of a standard solution of silver nitrate, containing 7.25 grms. per litre (1 cc. = 0.0025 gm. of NaCl), are added. After stirring, a drop of the solution is placed on paper impregnated with potassium chromate, the production of a red spot of silver chromate indicating that the whole of the chlorine of the common salt is precipitated. The addition of the silver nitrate solution, 1 cc. at a time, is, if necessary, continued until, on testing, a red colouration is obtained. Each 4 cc., or more exactly 4.07 cc., of the standard silver nitrate solution, corresponds to 0.01 gm. of sodium chloride in 10 cc., or to 1 gm. per litre, of the wine.—E. B.

Estimation of Tannins in Acid Liquors. A. Bartel.
Dingl. Polyt. J. 1891, 280, 233—234.

MEERKATZ (Der Gerber, 1889, 350) sought to overcome the difficulty which exists in the determination of tannins in acid liquors, by neutralising the liquor with barium carbonate before making the estimation, and maintained that there was no loss of tannin caused by this treatment.

The difficulty referred to arises from the action of the organic fermentation acids on the hide-powder used for absorbing the tannins, the results obtained being too high.

The author suspected that the excess of barium carbonate, which must necessarily be added, would precipitate some of the tannin, and instituted experiments with a view to settling this point. To 1 litre of an extract of oak bark 20 grms. of carefully purified barium carbonate were added, and the mixture shaken throughout a day. The solution was then filtered alongside of another litre of the same extract which had been treated in exactly the same way without the addition of barium carbonate. The tannin was then estimated in the two filtrates by Löwenthal's process, with the result that the one to which barium carbonate had been added contained 15.58 per cent. of tannin, while the other contained 22.28 per cent. Another experiment in which 5 grms. of barium carbonate were used gave similar results, as also did determinations made by the Schroeder indirect gravimetric method (this Journal, 1888, 647).

An experiment was also made to see if exact neutralisation with sodium hydroxide could be allowed. A portion of the oak bark extract was mixed with a little acetic acid and then with sufficient sodium hydroxide (previously ascertained) to neutralise this acid; the tannin in this solution, and in another similarly treated with the exception of the addition of acetic acid and sodium hydroxide, was determined by the indirect gravimetric method. The solution which contained the sodium acetate gave 18.93 per cent. of tannin, the other 26.28 per cent.

The author concludes that neutralisation of the acid liquor cannot be permitted.—A. G. B.

ANALYTICAL AND SCIENTIFIC NOTES.

Sodium. M. Rosenfeld. Ber. 1891, 24, 1658—1660.

SODIUM which has become coated with a crust by being kept under rock-oil can be easily purified without loss of metal in the following way:—The incrustated metal is first placed in a mixture of amyl alcohol (1 part) and petroleum (3 parts), and rubbed with a rag soaked in the same mixture until it acquires a silvery lustre; it is now placed for a short time in petroleum containing 5 per cent. of amyl alcohol, then washed with pure petroleum, and finally kept under petroleum containing 0.5—1.0 per cent. of amyl alcohol. Potassium and lithium can be purified and kept in the same way.

For preparing sodium amalgam the sodium is best purified in the manner just described; combination between the two metals then takes place very readily at the ordinary temperature.

The liquid alloy of sodium and potassium can be easily prepared in a short time by placing equal quantities of the two metals, purified as described above, in a mixture of

amyl alcohol (1 part) and petroleum (9 parts) and then pressing them together until liquefaction is complete; the alloy can be kept under petroleum.

Sodium sulphide can be very conveniently prepared by triturating sodium (1 gm.) with sodium chloride (3 grms.), and then mixing the grey powder obtained in this way with flowers of sulphur (0.7 gm.), but without employing any pressure; combination then takes place with development of light and heat, and the red monosulphide is formed, together with the yellow polysulphide. When quantities of sulphur corresponding to those required for the formation of the di- and trisulphide are used, a more energetic reaction takes place.—F. S. K.

Formation of Graphite by Contact Metamorphosis. R. Beck and Willi Luzi. Ber. 1891, 24, 1884—1886.

THE authors have recently found some beautifully crystallised specimens of graphite in rocks, which have undergone metamorphosis by contact with ancient volcanic rocks, the graphite crystals being in this case discernible from the amorphous carbonaceous substances of the original clay slates and siliceous slates. Although in our literature on this subject reference is made regarding the occurrence of graphite in certain slates which have been metamorphosed by contact with granite, proof of this is wanting owing to the absence of analytical and crystallographic data. These are now furnished by the authors, who have proved beyond doubt that graphite has been formed from carbonaceous substances by contact metamorphosis. In Pirna and Kreischau upper Silurian clay slates and siliceous slates have been found which are very rich in carbonaceous substances. They lie partially within the region of contact of granite and hornblende granite, and it has been found on close examination that those within this region of contact have become converted into rocks rich in graphite. A graphitic chialstolite slate and a graphitic quartzite were examined by the authors. The former was found embedded in the greatly metamorphosed upper Silurian grey trap of the Burkhardt Forest, whilst the latter proved to be a genuine contact rock from the immediate vicinity of the granite found in Kreischau. Both rocks have been formed from original siliceous slates, and their structure and chemical composition show that they are true contact products. The graphite from the chialstolite slate formed perfectly opaque jagged lumps, having a metallic lustre by reflected light, and being from 0.003 mm. to 0.02 mm. in diameter, whilst the carbonaceous portions in the unaltered upper Silurian clay slates and siliceous slates measured less than 0.001 mm. The quartzite from Kreischau was still richer in graphite. The latter was even more beautifully crystallised, single, well-defined crystals being 0.03 mm. in diameter. It occurred most frequently, however, in the form of irregular granules and jagged ramified crystalline aggregates measuring 0.3 mm. This graphite had a greasy touch and gave a metallic streak. The following results were obtained on analysis:—

	Carbon.	Hydrogen.
Graphite from the chialstolite slates	98.84	0.21
Graphite from the quartzite	99.94	0.05

The graphitic quartzite contained over 2 per cent. of graphite and had a specific gravity ranging from 2.62 to 2.637.—D. B.

Quantitative Determination of the Chemical Action of Light. Part III. The Influence of Dilution. G. Lemonic. Compt. Rend. 1891, 112, 1124—1127.

DETERMINATIONS of the decomposing action of light on solutions of oxalic acid and ferric chloride, present in equivalent proportions, but with varying amounts of water, were made. The authors consider that the physical effect of dilution may be disregarded, and the change effected

attributed to chemical action. From mathematical considerations they conclude further that, from the point of view of the influence of dilution, the chemical change effected by light and by heat follow the same law.—J. W. L.

PATENT.

Improvements in Centrifugal Apparatus for Testing Relative Volumes of Mixtures of Liquids of Different Specific Gravities. J. Laidlaw, Glasgow. Eng. Pat. 10,492, June 20, 1891. 6d.

New Books.

SOLUTIONS. By W. OSTWALD, Professor of Chemistry in the University of Leipzig. Being the Fourth Book, with some additions, of the Second Edition of OSTWALD'S "LEHRBUCH DER ALLGEMEINEN CHEMIE." Translated by M. M. PARTISON MITCHELL, Fellow of Gonville and Caius College, Cambridge. London: Longmans, Green & Co. New York: 45, East 16th Street. 1891.

IN the notice by the translator this paragraph occurs: "The facts amassed about solutions are now so many, and the theory is now so fully developed, that a systematic arrangement of these facts, and an authoritative statement of the theory, are sure to be welcomed by chemists." It is probably safe to add, "and Technologists," at the end of this paragraph.

The book is an 8vo. volume, bound in cloth, price 10s. 6d., and contains title page, Translator's notice, Preface, Table of Contents, list of Errata and Addenda, 310 pages of text, and an Alphabetical Index of names of investigators, as well as one of the matter treated of.

The text is sub-divided into groups or chapters described as follows: Chapter I. Solutions in Gases. II. Solutions of Gases in Liquids. III. Solutions of Liquids in Liquids. IV. Solutions of Solids in Liquids. V. Osmose. VI. Diffusion. VII. Vapour Pressures of Solutions. VIII. Freezing points of Solutions. IX. Salt Solutions. X. Simultaneous Action of several Solvents.

EXAMINATION OF WATER FOR SANITARY AND TECHNICAL PURPOSES. By HENRY LIEFMANN, M.D., Ph.D., Professor of Chemistry in the Woman's Medical College of Pennsylvania, &c., and WILLIAM BRYAN, Demonstrator of Chemistry in the Pennsylvania College of Dental Surgery, &c. Second Edition, revised and enlarged, with Illustrations. London: Kegan Paul, Trench, Trubner and Co. Ltd. 1891.

SMALL 8vo. volume, bound in cloth. Price 5s. It contains, Preface, Table of Contents, 118 pages of text, a set of tabulated Analytical and other data, and an Alphabetical Index. The text is illustrated with 17 excellently executed wood engravings exhibiting the various forms of apparatus described.

The subject-matter is classified as follows:—

The History of Natural Waters. Analytical Operations, classified as *Sanitary examinations* and *Technical examinations*. Interpretation of Results. Biological Examinations. Purification of Drinking Water. Identification of Source of Water. Technical Applications. Analytical Data.

A TREATISE ON THE LAW AND PRACTICE RELATING TO LETTERS PATENT FOR INVENTIONS, with an Appendix of Statutes, International Conventions, Rules, Forms and Precedents, Orders, &c. By ROBERT FROST, B.Sc. (Lond.), Fellow of the Chemical Society of Lincoln's Inn, Barrister-at-Law. London: Stevens and Haynes, Law Publishers, Bell Yard, Temple Bar. 1891.

LARGE octavo volume, bound in cloth. Price 28s. Containing Dedication page, to Sir Richard E. Webster, M.P., Preface, Table of Contents, List of Abbreviations used in the Work, Table of Cases, List of Addenda and Corrigenda, and subject-matter covering 741 pages. The Work closes with a very full and complete Alphabetical Index. The text is carefully paragraphed by marginal references and notes to assist search, and at foot of pages are given references to cases. Considerable prominence is given to leading chemical law cases.

The general treatment of the subject may be gleaned from the Chapter headings, which are as follows:—

Chap. I. The Patentee. II. The Subject-matter. III. Novelty. IV. Utility. V. The Specification. VI. Amendment of the Specifications. VII. Obtaining Letters Patent for Inventions. VIII. Assignment of Letters Patent. IX. Licences. X. Revocation of Letters Patent. XI. Prolongation or Extension of Letters Patent. XII. Action to restrain Threats of Legal Proceedings. XIII. Action of Infringement. Appendix, dealing with Statutes, International Convention for the Protection of Industrial Property, Orders, List of Fees, War Office Memorandum for Inventors.

FORTSCHRITTE DER THEERFARBENFABRIKATION UND VERWANDTER INDUSTRIEZWEIGE, 1887—1890. *And der Hand der Systematisch Geordneten und mit kritischen Anmerkungen versehenen Deutschen Reichs-Patente.
